As to the next point, I went so far in the matter of the variety of rays as to head one paragraph, "Cathode Rays of Various Kinds Are Variably Diffused." As intimated in his early papers, Lenard still reasons in the present open letter that there are "Rays of an unbroken series of an infinitely great number of different rays, varying gradually in properties."

Lenard has generally been misunderstood regarding the magnetic deflection of cathode rays, outside of the discharge tube. Dr. Lenard makes this point very clear. The book states on p. 66: "The author could not find in Lenard's papers, any positive or negative proofs that he had actually deflected the external cathode rays by a magnet, while passing through air or gas at ordinary pressures. * * * Dr. Lodge, who briefly reviewed Lenard's experiments, expressed the same opinion. See Elec. Lond. Jan. 31, 1896, p. 439."

Dr. Lenard modifies this by saying: "I have effected the deflection in hydrogen. The deflection is not visible in air of ordinary pressure, only because such air is too turbid to show any distinct rays at all, which could be distinctly observed at sufficient length to show deflectibility."

LITERATURE

THEORY AND CALCULATION OF ALTERNATING CURRENT PHENOMENA.—By C. P. Steinmetz, with the assistance of Ernst J. Berg. New York, 1897. W. J. Johnston & Co. 431 pp., 6 x 9 in. Cloth. Price, $2.50.

Those who have followed Mr. Steinmetz's work, especially in the field of magnetism and applied alternating current phenomena, will be glad to know that he has put himself on record in a formal way. This is a special cause for congratulation, because Mr. Steinmetz possesses in an eminent degree the faculty of a teacher. But in saying this we do not wish to lead any one astray by the belief that this work will enable the casual reader to avail himself of all of Mr. Steinmetz's knowledge. As here embodied, the work is by no means intended for beginners. Indeed it requires no little preparation to enable one to extract from it the large mass of useful and practical information which it contains; but for those equipped properly such as the graduates of our technical colleges ought to be, it offers a mine of information.

The author treats in detail the principal actions met with in alternating current work, both electrically and magnetically, and shows how these various phenomena affect the calculations of the designs, not only of electric machinery, but the external transmission lines. The work includes the treatment of the single phase as well as the various polyphase systems, and a number of appendices, among them one on oscillating currents.

There is no factor which may enter into the design of alternating current apparatus with transformers or machines that Mr. Steinmetz has not covered, and the experience which he has himself had in this direction has been largely drawn upon to furnish the material which he treats of. As stated above some mathematical knowledge is required to get a full appreciation of the work, but the numerous graphical methods employed by Mr. Steinmetz will, nevertheless, make it of considerable value also to those who have only a slim mathematical equipment.

TELEPHONY AND TELEGRAPHY

THE NEW TELEPHONE EXCHANGE FOR NEW ORLEANS.

For some time past the facilities of the existing Bell Telephone Exchange at New Orleans have fallen short of the requirements, but steps have now been taken to remedy that by the erection of a new building which shall embody all that is latest and best in exchange construction and operation. By August 1 the company will move into its new home, which will be erected at the corner of Carondelet and Poydras streets, opposite the present exchange.

Work on the structure commenced immediately after Mardi Gras. The contract, which has caused quite a lively competition among builders from all sections of the country, has been awarded to the firm of Murdoch, Campbell & Co., of Chicago. The piling for the structure was laid some time ago, and it is considered strong enough to hold a building twice the size of the one contemplated. A cut of the building accompanies this article, and a glance at it will show that the new exchange is going to be one of architectural beauty.

GREAT SOUTHERN TELEPHONE AND TELEGRAPH CO.

New Telephone Exchange of Great Southern Bell Co., New Orleans, La.

As will be seen in the cut, the building will be five stories high and will occupy the entire vacant space at the corner of Carondelet and Poydras streets. The entire structure will be built of stone and iron, and will be fireproof throughout. Nothing conducive to the comforts of the large number of people employed by the company has been overlooked.

The entrance to the building will front on Carondelet street. It will be very ornamental in design, and will have a large vestibule finished in marble. There will be two other entrances on Carondelet street—one to the public telephone station and the other to the workshop. The rest of the ground floor will be a large store with an entrance on Poydras street, which will be used for rental purposes. In the rear southwest corner of the ground floor will be stationed the engine room for heat, generating power and pumping. In the rear of this room will be the cable shaft, extending from sub-conduits to the fourth floor for the purpose of carrying all cables and wires which enter the building. The estimated number of wires that will go up this shaft is ten thousand, which means five thousand subscribers on the metallic system.

The second floor will be devoted to office purposes, and when finished will present one of the neatest and best appointed counting rooms in the city. About two-thirds of the second floor will be sub-divided by handsome partitions, which, while leaving the entire counting room as one room, will give privacy to the various departments. The office of the president will be situated on the south side of the cable shaft. In the rear of this office a room will be set apart for the archives. Immediately in the rear of this will be the toilet rooms, which will be finished in marble and will be equipped with every modern improvement. Abutting this on the southwest corner will be the continuation of the second story cable shaft.

The third floor will be finished in one large room, which for the present will be considered a workshop and overflow department for general supplies. The southwest corner of the room will be later set aside as a division for the electricians and engineers.

The fourth floor will be the special feature of the building, as it is upon this floor that the more modern ideas will be introduced in the new switching plans to be provided. In selecting the building site the question of access and distribution of wires was quite an important factor. Coupled with this advantage the question of light and comfort of the large number of employés, necessarily required in the operating department, were quite material. This room will receive its light from three large arched windows and two single windows on the Carondelet street side, and the same number and same style of windows on the Poydras street side. The switchboard and modern apparatus which will be stationed on this floor will occupy nearly the entire room. In the rear south end of the floor space on this floor will be located a mezzanine floor that will include bath rooms, drying rooms and lockers. Immediately under this floor space will be an elaborate system of marble finished toilet rooms and a storage battery and power plant. On the southwest corner will be the lunch room, about fifteen by fifteen feet in size, which will be equipped with a novel heating apparatus. It will also contain a library and such additional details as will make the room an enjoyable one of recreation for the lady employés, who will be exclusively in charge of this floor in its various departments.

The whole work is being actively pushed by General Manager Fowler, whose long experience in the telephone field has given full knowledge of what is best to do and what methods are best to adopt.

NIAGARA POWER TRANSMISSION TELEPHONE SERVICE.

AN interesting special telephone service has been put in for use in connection with the Niagara Falls power transmission, so as to render possible at any time instantaneous communication between all parts of the network of power circuits. The telephone lines consist of two No. 12 hard drawn copper wires, strung all the way between the Cataract Company's power house and the office of the Buffalo General Electric Company in Buffalo. On this circuit one telephone is located in the office of Mr. C. R. Huntley, of the Buffalo Company, and a second one in the power house of the Buffalo Railway Company. These two telephones and one in the Cataract Company's power house, remain in circuit constantly. In addition to this "long-distance" service, the contractors, White-Crosby Company, have also erected fifty telephones along the line, placed half a mile apart and enclosed in cast iron boxes similar to those ordinarily containing police telephones in cities. These are so made that when the door of any one of the cases is opened, the telephone within is thrown into circuit. At other times, all these line instruments remain cut out. This method enables any one patrolling the line to go to the nearest telephone and call up either of the three instruments above referred to that are regularly in circuit. Thus the whole line is in touch with its extremities.

Supplementary to this, an ordinary metallic circuit system has been installed, a 50-drop switchboard being placed in the Cataract Company's power house at the Falls. The circuits to and from this connect up all the instruments in all the various establishments taking power from that plant. The telephonic apparatus was made by the Phœnix Interior Telephone Company, of New York City.

THE HAWAIIAN CABLE.

The United States Senate committee on naval affairs has recommended the incorporation in the Naval bill of Senator Lodge's proposition to appropriate $25,000 to take soundings for a telegraph cable between the Hawaiian Islands and Japan.

ELECTRIC TRANSPORTATION

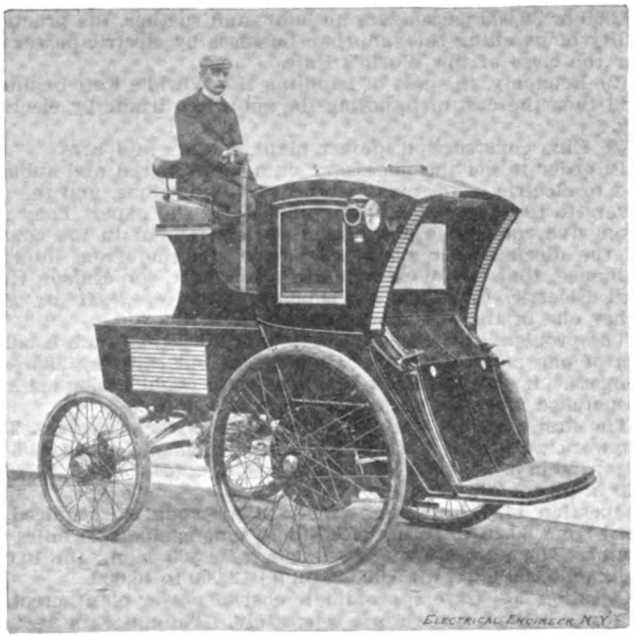
ELECTRIC HANSOM CABS IN NEW YORK CITY.

MUCH attention is now being attracted in this city by a number of electric hansom cabs. These vehicles have been built by the Electric Carriage and Wagon Company, who have installed a depot at 140 West Thirty-ninth street, close to the Edison station, whence the current for charging the batteries is now derived.

The accompanying engraving, made from a photograph, gives an accurate idea of the appearance of the cabs, which differ from the usual hansom in that they have four wheels instead of two, and an extension for the batteries. The batteries are contained in this rear compartment upon which the driver's seat is mounted, and consist of four sets of cells, weighing together about 1,000 pounds.

The steering is effected by a lever which the driver handles with his right hand, as shown in the engraving. With his left hand, he controls the current by operating a small hand wheel. The brake is operated by foot, as is also the whistle. Two motors of the Lundell type drive the front wheels by means of spur gearing.

All the wheels are provided with heavy pneumatic tires. The front pair are fixed, the cab being steered by the rear wheels. The rear axle is also fixed, but to permit of steering, the rear wheel hubs are hollow and are provided with ball joint journals, so that they move independently of the axle. The side lights are small incandescent lamps and a lamp is also provided on the inside of the cab.



ELECTRIC HANSOM CAB, NEW YORK.
(*From Photograph.*)

The cabs have a maximum speed of 15 miles per hour, which is found to be more than necessary to meet all the requirements of city and country travel, although in case a greater speed is called for it can be had up to a rate of 20 or 25 miles per hour, but, of course, only at the expense of the total distance which the vehicle can travel. The vehicles have a maximum mileage on one charge of battery of about 25 miles, depending largely on grades and surface conditions to be overcome.

The cost of operating, with properly equipped stations, is said to be about one-half that of horses. That is to say, assuming that on an average it costs about $1 per day to keep a horse, including the life of the horse, the cost of operating one of these vehicles capable of doing the same amount of work as a horse will not exceed 50 cents per day. As the size of the battery at present used only has a capacity of 8 horse-power hours, the cost of charging, where power is produced at the station, should not exceed 2 cents per horse-power hour, or 16 cents, and when obtained from central station 5 cents per horse-power hour, or 40 cents. To this, of course, must be added 10 per cent. depreciation per annum chargeable to battery renewal, etc.

One of these cabs is employed by Proctor's Theatre for advertising purposes and an electric delivery wagon built by the company will shortly be put in service by a large New York dry goods house.

WALLACE ON ELECTRICITY FOR SUBURBAN RAILWAY TRAFFIC.

At the last meeting of the American Society of Civil Engineers, there was presented a paper by Mr. Wallace, chief engineer of the Illinois Central, entitled "The Substitution of Electricity for Steam as a Motive Power for Suburban Traffic." It was a statement of the chief results of a very careful study made by Mr. Wallace in 1892 in the course of preparation for handling the World's Fair traffic between Van Buren street, and the Exposition grounds. The paper is not offered as a solution, even approximate, of this difficult problem; but the purpose is to place before the members of the society the facts as ascertained by that inquiry, with the hope of drawing out discussion, and other papers from experts in this special line of work. This matter of applying electric power to suburban service is again under consideration by the Illinois Central, and Mr. Wallace promises to give further information in a later paper or in the concluding discussion on the present paper.

He divided the problem into the questions of

(1) Practicability, covering the possibility of carrying 10,000 20,000 or 30,000 passengers an hour; and further, the practicability of handling the suburban business by electric power after the close of the World's Fair.

(2) Economy, the cost of handling the World's Fair business and then the cost of handling the suburban traffic by electricity.

(3) Line construction, power plant, motors and cars.

In order to get the necessary data he prepared and submitted to electric companies a series of 45 questions, and the answers to these questions are embodied in the paper. They are from five companies designated by letters; but in the course of the discussion a guess was made, judging from internal evidence, that (a)=Westinghouse, (b)=Short, (c)=Edison General Electric, (d)=Thomson-Houston and (e)=Daft or any other one of three or four companies.

The problem given was to haul 60 or 70 trains, each consisting of one motor car and two trailers, and carrying 336 passengers. It was assumed that one train could be loaded and dispatched from the terminal station each minute.

The first question was as to the horse-power of motors. The answers were: (a) Two of 75 h. p.; 150 h. p.; (b) two of 75 h. p.; 150 h. p.; (c) four of 50 h. p.; 200 h. p.; (d) four of 25 h. p.; 100 h. p.; (e) 200 h. p.

Question 14.—How much power plant would be required to haul from 60 to 70 trains of 65 to 70 tons each, at 20 miles an hour? The answers to these are: (a) 4,800 h. p.; (b) 10,000 h. p.; (c) 5,000 h. p.; (d) 5,000 h. p.; (e) 12,000 to 15,000.

Question 20.—Give approximate cost of power plant, erected, engines, boilers, generators, separately. The answers are: (a) $475,000, not including real estate, which is almost exactly $100 per horse-power. (b) $1,000,000, being $60 per horse-power for the steam plant and $40 for the electric plant. This includes the cost of building; (c) $320,000, or $65 per horse-power; (d) $455,000, or $91 per horse-power, including the cost of building. This is divided, building, $10 per horse-power; dynamos, $35; steam plant, $46; (e) $1,169,000 or $77 per horse-power, not including the building.

Question 21.—Give estimated cost for operating power plant with coal at $1 per ton. The answers are: (a) $60,000 per year, including fuel, labor and repairs; (b) $30 per horse-power, operating 18 hours a day or for 7,500 horse-power, a total of $225,000 a year; (c) Fuel cost $4 an hour, being 2 lbs. of coal per horse-power per hour; labor account $17 a day; (e) $420 a day of 12 hours.

Question 42 is, What will be the percentage of loss of power between the steam engine and the motor? This is estimated by (a) at 33 per cent.; by (b) and (c) at 50 per cent., and by (e) at 15 per cent.

Questions 36 and 37 ask, What time would be required to build and equip the plant, and whether the company would guarantee on its own specifications, at an agreed price, the successful installation and operation of the plant? The companies were willing to undertake to do the work in one year. (a) was willing to guarantee performance; (b) was willing to make a guarantee under heavy penalties; (c) would like a chance to try one train; (d) was willing to make a guarantee; (e) did not answer.

Question 5 was, What is the best method to transmit the power of the motor to the axle, by gear or by crank? To this (a) replied by placing the armature directly on the axle, or by steel gears. (b) was perfectly well satisfied that there was no method admissible but a gearless motor; that is, with the armature on the axle. (c) preferred cranks or parallel rods. (d) and (e) both recommended gears.

DESTRUCTION OF RAILWAY POWER HOUSE IN PHILADELPHIA.

Through some very extraordinary carelessness in the handling of a crane in the power house of the Union Traction Co., at Thirteenth and Mount Vernon streets, the whole plant was destroyed by fire on the night of March 3, throwing a large part of the system into confusion and delaying several lines of cars until current could be switched on from other sources. The power house in question was equipped with three Westinghouse generators of 2,000 horse-power and one which, it is said, was being worked over into a capacity of 2,500 horse-power. These were driven by Wetherell-Corliss engines. There were also five Westinghouse "Kodak" generating units of 600 horse-power each. In the boiler room there were sixteen boilers of 350 horse-power each. The whole plant and building were valued at about $500,000. It appears that in passing the crane over one of the large units, the hook was allowed to trail across the field and armature, causing a short circuit, which flung around red hot metal and insulation and set fire to the oil soaked wooden floor. The men in the station tried to extinguish the fire, but could not do so. The fires under the boilers were drawn with great difficulty, but the main steam pipe burst and the roar of the escaping steam added greatly to the confusion and alarm. The plant is reported to be fully insured.

THE TROLLEY STEAM FIGHT IN NEW ENGLAND.

The New England Railroad Company has practically withdrawn all opposition to the trolley line to New Britain. When the case is called in the Superior Court, before Judge F. B. Hall, the company will enter no appearance or consent to judgment against it. An agreement to this effect has been entered into, and the Newington Tramway Company and the Central Railway and Electric Company of New Britain will at once build the road. This agreement is made as the result of a compromise by which Section 8, the anti-paralleling clause, of the street railway law of 1895, is not to be disturbed by the General Assembly, but will remain on the statute book as a protection alike to the steam roads and the trolley lines.

STREET CAR FREIGHT SERVICE AT COLUMBUS, O.

The Columbus (O.) Central Street Railway Company will soon establish a freight service on the Westerville division of their lines between the city and the suburb of Westerville. It is the intention of the company to build a car especially designed for carrying freight. The new car will be about the same size of the ordinary cars now in use on the lines of the Central. The business will be handled somewhat after the manner of express business. The car will be placed on the spur at Town and High streets in charge of a man who will give a receipt for all goods turned over to him for transportation. The car will remain there during certain hours to be designated later and when the time comes for it to leave it will be attached to a regular Westerville motor car.

When the Westerville end of the line is reached the car will be left there for a certain length of time during which the goods can be unloaded and packages for Columbus will be received. The rate to be charged for handling freight has not yet been decided upon but it will undoubtedly be less than the express rate which is 25 cents for packages of less than 100 pounds. The number of trips to be made by the car each day will be as frequent as the business warrants, and if necessary additional freight cars will be built to accommodate the business. A service of this kind has long been desired by the people of Westerville, who are greatly pleased with the plan.

"VALUABLE."—The Electrical Engineer is a most reliable and valuable paper, for both young and old—educated and uneducated. We can recommend it as the most valuable journal treating on scientific electrical appliances.—Passaic (N. J.) Item.

SOCIETY & CLUB NOTES

LAMP TESTING BUREAU PROPOSED FOR THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

PRESIDENT NICHOLLS of the National Electric Light Association, has just issued his Interim Report No. 3, discussing a number of questions of considerable interest to the members.

Referring to the work of the Committee on Standard Lamp Socket, attention is called to the meeting held for the purpose as detailed in The Electrical Engineer at the time, and while progress has been made since then some unforeseen difficulties have arisen. At the last meeting of the National Board of Fire Underwriters the rule relating to sockets was amended as follows. "No portion of a lamp socket or lamp base, exposed to contact with outside objects, must be allowed to come into electrical contact with either of the conductors." The proposed standard base and socket would therefore have to conform to this rule.

The Committee on Data has tabulated valuable statistics which are now in the hands of the printer.

The Committee on Incandescent Lamp Standards reports the results of its conferences with the Units and Standards Committee of the American Institute of Electrical Engineers and the establishment of a standard method and apparatus for the measurement of candle-power has been satisfactorily settled, and it now only remains to produce secondary standards—that is, standard incandescent lamps to be used for purposes of comparison—and to draw up proper specifications for uniform rating of lamps and its ready verification.

President Nichols submits also a plan for establishing a lamp testing bureau which we give in full below:

PLANS FOR ESTABLISHING A LAMP-TESTING BUREAU

The proposed bureau to be in charge of an expert employed by the National Electric Light Association, and methods of testing to be approved by a majority of experts of lamp manufacturers, who agree to abide by decisions of the bureau as to quality of product and fulfillment of guarantees.

Any lamp company, whose lamps are being tested at the bureau, will be allowed at any time to investigate the methods used and the accuracy of standards, but to have no access to records of the bureau, except as regards tests which have been, or are being, made on their own product.

The expense of maintaining the Testing Bureau will be met by the income of the Bureau, as hereinafter provided, by certain definite charges for tests made, and could also probably be partially met by subscription or definite dues from central stations or other consumers, who would signify their intention of availing themselves during any year of the services of the bureau.

Lamp companies would be at liberty to guarantee their product at as high a standard of quality as they see fit, and the province of the bureau would be to determine whether such guarantees have or have not been fulfilled. Tests will be made by the bureau on guaranteed lamps furnished by any manufacturer, on application by the customer, the following conditions having been complied with:

1. Before test is made, the customer ordering the test should deposit with the bureau a sum equal to the estimated cost of such test at the following rates:

Initial tests or readings of lamps will be made at....cents per lamp. Tests will be made to determine the value of a lamp burned at its marked voltage at....cents per thousand watt hours.

Conditions under which tests will be made are as follows:

1. Not less than twenty lamps will be tested to determine the value of any given lot of lamps.

2. Where the value of any lot of lamps is to be determined, not less than two per cent. of the entire number whose value is to be determined are to be furnished the bureau for test in their individual unbroken packages (this would only necessitate the placing of a seal or label on the wrapper of each lamp in such a manner that it must be broken to unwrap the lamp) within thirty days after their receipt by the customer.

NOTE.—Where the number of lamps used in a year by the customer is comparatively small, so that a number of shipments from the manufacturer would be required in order that two per cent. of the entire number should equal twenty lamps, two per cent. of each shipment may be sent to the bureau within thirty days after each shipment, and the test not made or ordered by the customer until twenty lamps have been received by the bureau, provided that such test is ordered within one year from the receipt of the samples from the first shipment.

3. Where tests are requested to determine the value of the lamp by burning it at its marked voltage, an initial test will first be made on lamps furnished, which, as above provided, must represent not less than two per cent. of the lamps, the value of which is to be determined. One-half of these, which most nearly represent the average result obtained on the initial test, will be burned at their marked voltage until their value is determined, in accordance with the guarantee. Should any lamp be accidentally broken during the test, its place shall be taken by a reserve lamp, which, on initial test, most nearly represents the broken one. The average result obtained from the test of these samples determines the value of the lamps represented by the samples.

4. The results obtained by tests made by the bureau should, by agreement on the part of the lamp manufacturers and of customers who avail themselves of the services of the bureau be final, claims being settled in accordance with its findings, upon a definite basis agreed upon between manufacturer and customer.

In order that the proposed bureau shall be of value enough to entitle it to the support of lamp companies and their customers, a definite basis of value for a lamp should be determined by agreement between manufacturers and their customers who are to support the bureau. Though lamp companies should be at liberty to guarantee their product at as high a standard of quality as they see fit, the general lines on which such quality is to be determined should be agreed upon by all concerned. The following basis is, therefore, suggested:

1. The effective life of a lamp is to be considered as ending when the lamp reaches some certain percentage of its initial candle-power reading, the value of a lamp being determined by the candle hours given by burning the lamp at its marked voltage and taking readings of candle-power at intervals of 100 hours until the candle-power falls to....per cent. of its initial rated candle-power at the marked voltage; or should the lamp tested burn out before reaching....per cent. of its initial candle-power, it is credited with its actual performance.

Initial readings should be the secondary, and of small value compared to the actual performance of the lamp in service, though manufacturers should guarantee their lamp for an individual variation in candle-power of not to exceed....per cent., and an average variation of not to exceed.... per cent. Economy or watts should allow for an average variation of not to exceed....per cent.

2. The guarantee to the customer should provide that, where the customer requests a test made by the bureau, the cost of the test is to be paid, and certain penalties observed, as follows:

If an initial test only is requested, where one or more lamps are found outside the guaranteed initial range as to candle-power, the customer is entitled to a....per cent. reduction in price of lamps represented by the samples furnished the bureau. If average economy is found outside the guaranteed range, the customer is entitled to a....per cent. reduction. The cost of the above initial test is to be paid by the customer if the lamps are found inside the guarantee, and by the manufacturer if found outside.

Where tests are requested to determine the area, or candle hours, an initial test will first be made on lamps furnished, which, as hereinbefore provided, must represent not less than two per cent. of the lamps, the value of which is to be determined. One-half of these which most nearly represent the average result on initial test will be burned at their marked voltage, and the candle hours determined.

The average results obtained from the test of these samples determines the value of the lamps represented by the samples. Should the average candle hours, or area, fall below the guarantee not more than....per cent., the manufacturer shall only pay the cost of the test. Should the candle hours, or area, fall more than....per cent. and less than....per cent. below the guarantee, the customer is entitled to a....per cent. reduction in price of lamps represented by the lamps tested, and the manufacturer to pay the cost of the test. Should the average candle hours, or area, fall below the guarantee by more than....per cent. and less than....per cent., the customer is entitled to a....per cent. reduction in price of lamps, and the manufacturer to pay the cost of the test.

The above percentage of reduction, or penalty, to be continued in proportion until the customer obtains the lamps (no charge), the manufacturer paying the cost of the test.

Should the average candle hours, or area, be at or above the guarantee, the customer shall pay the cost of the test.

As above provided, where tests are requested by the customer, check should be sent to the bureau before the test is made, covering the estimated cost of the test.

Although not an important point, I believe it would greatly stimulate advance in quality of lamps, to the benefit of both consumer and reputable manufacturers, if every six months the average results of all tests made on the product of different manufacturers were published in the electrical journals, such results to separate various economies, and placing in different classes lamps of voltages from 45 to 60 volts, and lamps from 100 to 125 volts; also separate results on any test which might be made on lamps from 200 to 250 volts.

The following papers are announced to be read at the next convention:

W. Worth Bean, St. Joseph & Fort Benton Railway & Lighting Company, "Municipal Lighting"; J. B. Cahoon, Elmira Municipal Improvement Company, "Standardizing Prices for Incandescent Light and Power"; C. L. Edgar, Boston Edison Company, "Correct Method for Charging for Product"; W. S. Jewell, Toledo Traction Co., "Cost of Delivery of Current from Station to Customer"; T. C. Martin, Editor The Electrical Engineer, "The Daylight Work of Central Stations"; L. B. Stillwell, Cataract Construction Company, "Electrical Development at Niagara"; Prof. Elihu Thomson, Lynn, Mass., "Recent Progress in Arc Lighting"; J. G. White, White-Crosby Company, "The Niagara Power Transmission Line"; Prof. C. A. Wilson, Professor of Electrical Engineering at McGill University, Montreal, "The Induction Factor, a New Basis of Dynamo Calculation and Classification"; Arthur Wright, President Municipal Electrical Association, England, "The Profitable Extension of Central Stations."

INTERNATIONAL EXPOSITION IN BRUSSELS.

The International Exhibition, to be held in Brussels, will open on April 24 and close on Nov. 15. The section of science is expected to be especially rich in exhibits illustrative of the latest progress and the co-operation of many of the leading scientists in Europe has been secured. This section will be divided into three classes. Class A will cover mathematics, astronomy, physics and chemistry. Class 2 includes geology and geography, biology and anthropology. Class 3 will be devoted to bibliography. Transportation by the Belgian railways will be granted free of charge. Reductions on the charges for transportation will also be made by other Europeon railways. Persons desirous of exhibiting in the Class for Physics can obtain all necessary details by applying to M. E. Rousseau, professor at the University of Brussels, 20 Rue Vautier, Brussels, Belgium, or to the secretary, M. L. Gérard, professor at the University of Brussels, 6 Rue du Mèridien, Brussels, Belgium.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

As already announced by us, the National Electric Light Association has decided to hold its next, or twentieth, convention at Niagara Falls, N. Y., and June 8, 9 and 10 have now been selected as the time of meeting. The place is one of utmost interest to electricians, and a large attendance is expected.

TENNESSEE CENTENNIAL EXPOSITION.

New York State will erect a State Building at the Tennessee Exposition. The small appropriation renders it necessary to exercise much economy, and as it is desired to light it well by electricity and to make it cool during the hot weather by means of fans, it is suggested that some manufacturer willing to secure publicity in return for his liberality might be willing to supply a small plant run by steam or gas engine. An offer has already been made of electric light fixtures for the building. Mr. Algar M. Wheeler, secretary of the New York State Commission, may be addressed on the subject at his headquarters, Gilsey House, and 28 West Thirtieth street.

"FULL OF INFORMATION."

"I like your magazine," writes a subscriber in the Northwest, "for the reason that it is full of information about the common everyday business of a plant. We can never know too much about the coal we use, or about speed, belts, belt dressing, oils, treatment of dynamos and motors, lamps, wiring, etc. Many of your patrons are new to the business, and even the older ones are changing places. The abstruse part of electrical industries interests a good number of your readers, but the stations like to read of the daily doings and the common facts. The Data Sheets are good."

MECHANICAL

THE QUIMBY ELECTRIC SCREW PUMPS.

Few realize how much of the total power consumed in civilized communities is absorbed in pumping of one kind or another. Let alone steam power establishments of all kinds, modern domestic life and commerce have brought the pump into use in a variety of places not thought of or required twenty years ago.

Electric power has served to increase largely this use of pumps, for elevator, domestic, and other purposes, and one of the latest departures in this direction is the Quimby screw pump, built by Mr. William E. Quimby, of 59 Liberty street, New York.

The general form and construction of the Quimby screw pump is illustrated in Fig. 1. The four screws that act as pistons in propelling the water are mounted in pairs on parallel shafts and are so arranged that in each pair the thread of one screw projects to the bottom of the space between the threads of the opposite screws. The screw threads have flat faces and peculiarly undercut sides; the width of the face and the base of the thread being one-half the pitch. The pump cylinder fits the perimeters of the threads, as shown in Fig. 2. Space enough is left between the screws and the cylinder, and between the faces of the intermeshing threads to allow a close running fit without actual contact. There is no end thrust of the screws in their bearings, because the back pressure of the column of liquid is delivered to the middle of the cylinder and the endwise pressure upon the screws in one direction is exactly counterbalanced by a like pressure in the opposite direction.

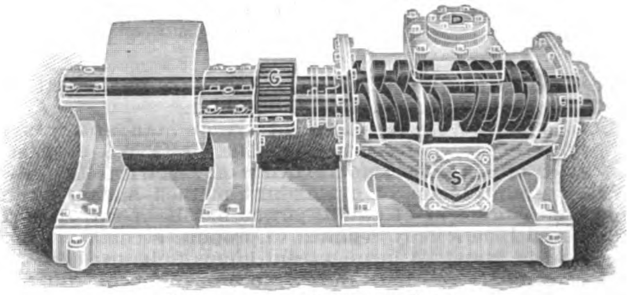


Fig. 1.—Quimby Screw Pump.

The suction connection is shown at S, Fig. 1, and opens into a chamber underneath the pump cylinder. The suction liquid passes through this chamber to the two ends of the cylinder and is forced from the two ends toward the center by the action of the two pairs of intermeshing threads; the discharge being in the middle of the top of the cylinder, as shown at D, and the second shaft is driven by means of a pair of gears. The power to drive the pump is applied to one of the shafts, shown at G in Fig. 1.

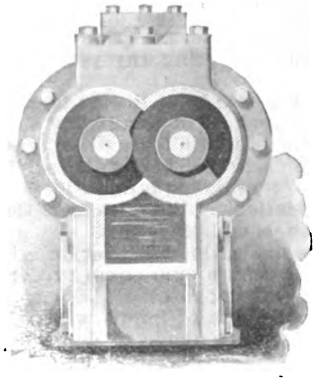

Fig. 2.—Quimby Screw Pump.

The pump has no internal packing, no valves and no small moving parts. The only packing is in the stuffing boxes where the two shafts pass through the cylinder head. As these stuffing boxes are on the suction end of the pump there is no tendency to blow out the packing.

The advantages of this type of pump are apparent. Whether driven by a belt, an electric motor, or a steam engine, the driving power is applied directly and without the loss due to intermediate mechanism.

Having no valves, no internal packing, and no small moving parts, there is very little opportunity for the pump to get out of order; and as the screws are not in contact with the cylinder or with each other, the consequent absence of wearing surfaces gives the pump great durability.

The efficiency of the pumps is also high, because the power is applied direct; the thrust due to back pressure of the column of liquid in the delivery pipe is perfectly balanced. Owing to the absence of rubbing surfaces there is an absence of internal friction; the rotary motion of all the moving parts and the continuous flow of the liquid delivered also contribute to the efficiency.

Fig. 3 shows one of the Quimby screw pumps direct connected to an electric motor. This type is admirably adapted for house service, in connection with an automatic tank switch. Being mounted on the same bed plate, the combination is specially adapted for temporary use and is easily transported.

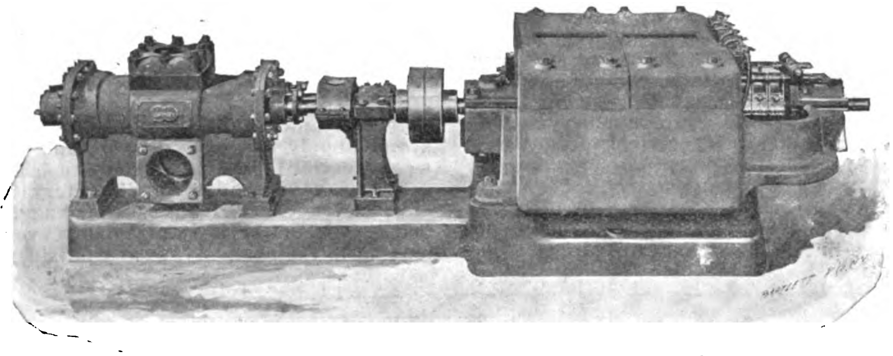

Fig. 3.—Quimby Electric Screw Pump for House Service.

A large number of these pumps have already gone into operation and several can be seen at work in this city on house and elevator service.

PERSONAL

EDWARD M. BENTLEY.

WITH the successful operation of a conduit road in Washington and the coming introduction of this system on a large scale in New York, it is interesting to recall the fact that the first electric street railway in the United States was of this kind. It was started in the summer of 1884 at Cleveland, Ohio, having been constructed by E. M. Bentley and W. H. Knight, two Patent Office examiners, who had resigned to undertake this work. This road was operated for over a year with as much success as could be expected from the primitive electric railway appliances available at that early period, and it led to the formation of the Bentley-Knight Electric Railway Company, which occupied a prominent figure in the early electric railway business until 1889, when it was absorbed by the Thomson-Houston Company.

The Bentley-Knight conduit road at Allegheny City, built in 1887, was in successful operation for several years, and resulted in the building of a conduit road in Boston, on Boylston street, in the following year. This road began operating in mid-winter under most adverse conditions, and as its failure would obviously promote the introduction of the much cheaper overhead system into Boston, it is needless to say that the conduit was not made a success. Its construction, however, was not essentially different from that of the new conduits of Washington and New York, which have been built under the Bentley-Knight patents.

Of these two electric railway pioneers, Mr. Knight became the chief engineer of the railway department of the General Electric Company, and held the position until he was secured by the Whitney syndicate to develop the compressed air motor, and now has charge of that enterprise.

Mr. Bentley, on going with the Thomson-Houston Company, took charge of its department of patents and inventions, and held the position until the removal of the General Electric Company's works to Schenectady. Mr. Bentley is now practicing independently as a patent expert and solicitor of patents, with an office in Temple Court, New York City. He has continued to represent the General Electric Company in its most important patent litigation, having acted as its expert in the suits on the Van Depoele trolley and switch patents, the suits brought against it on the Tesla patents and others. Few, if any, patent experts have had a more extensive and valuable experience to fit them for their duties than Mr. Bentley, who has, moreover, been admitted to the bar as a lawyer. Those having important patent rights to protect, or inventions to be patented, will be interested to know that he is now engaged in general practice, and does not confine himself entirely to electrical subjects.

MR. J. W. BRAID is the chief of the electrical department of the coming Tennessee Centennial Exposition.

MR. JOHN A. HIGHLANDS has been appointed general superintendent of the Hudson River Telephone Company in the place of the late W. H. Cull. Mr. Highlands is an able telephone engineer, is a graduate of the Massachusetts Institute of Technology, and while at Harvard was a nationally famous pitcher in its baseball team.

MR. B. J. ARNOLD, of Chicago, will begin at the University of Nebraska, Lincoln, Neb., on March 15, a series of ten lectures on central station design and construction.

MR. S. INSULL, president of the Chicago Edison Company, was in New York City last week on business, having come on from Washington where he was one of the party with the Governor of Illinois at the McKinley inauguration.

MR. W. J. CLARK, of the Railway Department of the General Electric Company returned to New York last week after a Western trip. He found business conditions decidedly on the mend, and a much better feeling prevalent.

MR. F. J. SPRAGUE injured his leg by a bad fall last week while directing some work at the new Astor Hotel, but escaped fortunately with slight wounds.

MR. A. J. WURTS.—Among the numberous exhibits of the work of graduates of the Stevens Institute of Technology shown during the recent celebration of its 25th anniversary, was that of Mr. A. J. Wurts, of the Westinghouse Company. The exhibit consisted of two marble switchboards with automatic cut-outs, a lightning arrester board, and framed photographs, showing other work of Mr. Wurts. The lightning arrester board has been presented to the Institute by the Westinghouse Company, and the photographs also, by Mr. Wurts, and will be added to the permanent exhibition of the Institute.

MR. W. H. BRENNER has been appointed constructing engineer of the New York and Staten Island Electric Company.

MR. F. SARGENT, the consulting electrical engineer of Chicago, has recently been in New York, and is now making a Southern trip.

MR. C. F. SCOTT, electrical engineer of the Westinghouse Electric and Manufacturing Company, lectured recently in Pittsburg before the First Congregational Church on "Electricity."

MR. JOHN M. WARD, the famous baseball shortstop, now a lawyer, has been engaged by the Nassau Electric Railroad Company to take charge of its claim department, taking over a good deal of the work done by J. C. Church, secretary and counsel of the company.

NEWS AND NOTES.

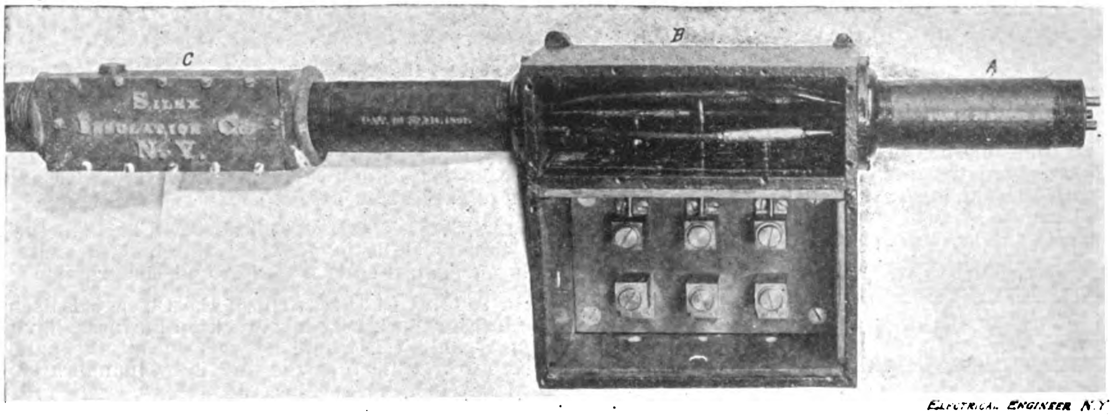
SILEX, THE IDEAL FIRE PROOF INSULATION.

BY OSCAR MOHLE.

TO the Engineers' Club of New York belongs the credit of having in their new home, at No. 374 Fifth avenue, the first absolutely fireproof system of vertical mains for electrical conductors. To any one unfamiliar with the material silex, this might seem at first blush to be a very bold statement. Much has been written during the past six months in the electrical and insurance press about the properties of this insulator, and the following facts are noteworthy:

Silex (di-oxide of silicon) controls electric currents of the highest tension. It has an extraordinarily high fire resisting quality, fusing only at the temperature of the oxy-hydrogen flame, and is practically a non-conductor of heat. It is non-hygroscopic and absolutely proof against the action of water. Its specific inductive capacity is extremely low, being from 10 to 250 per cent. less than any other insulation now in use.

How to apply this substance, so that its undoubted advantages as an insulator could be utilized by providing a reliable safeguard to life and property, has been the task of the Silex Insulation Company, 39 and 41 Cortlandt street, New York. The accompanying engraving shows a section of the system as installed in the above-mentioned club. The steel tubes A contain three No. 0 copper wires imbedded in finely pulverized silex, solidly packed, so as to prevent any possible change in their relative positions, either through careless handling in transportation or installation. These are connected with the street service at the house line in the cellar, continuing along the ceiling to the elevator shaft and thence rising to the top of the building.



OUTLET BOX AND PIPE JOINT FOR SILEX INSULATING SYSTEM.

The lengths in the cellar are joined by a special coupler, C, allowing ample room for connecting conductors, which is then thoroughly packed with silex. At each floor the tube passes through a junction or outlet box, B, in one side of which connections are made, and the space likewise filled in with silex and sealed. The other side of the box is properly slate lined and provided with binding posts for safety fuses of branch circuits. This, in brief, describes the component parts of the silex system of mains.

It has now had a continuous trial for four weeks, and is giving eminent satisfaction.

SOME BRUSH HISTORY THAT IS NOT SO.

SOME curious electrical history finds its way into the daily papers now and again. After circulating awhile it becomes accepted as fact, and thereafter it is a difficult task to show that it is in reality without any foundation. A striking example of this kind of stuff is furnished by the item quoted below, the story being told by "Tip of the Tongue" in one of the New York dailies:

"I wonder what has become of my old friend, Emil Bixel? In 1878 he was keeping a small drug store in Cleveland, Ohio, and had saved up $2,500 which he wanted to invest. The Brush Electric Light Company had just then been organized, and was struggling along in a diminutive factory in the outskirts of the city. One of the officers, hearing of Bixel's $2,500, offered to sell him for that sum $10,000 of the stock in the company, and drove him out to see the plant.

"'Shuh! I wouldn't give $250 for the whole thing,' said Bixel in disgust, and returned to his business.

"I have kept track of that stock. If Bixel had bought it for $2,500 he would have made in sixteen years $240,000.

"Brush got his start in an interesting way. There lived in Harlem two maiden ladies upon whom he frequently called and to whom he was everlastingly talking about his inventions and the difficulties of obtaining funds with which to introduce his light. One became so deeply interested that she persuaded her sister to mortgage their house for $30,000 and lend the money to Brush. Their income from the investment reached the handsome sum of $10,000 a month when the light became well established.

"Brush was too poor to pay the fees of his patent lawyer. They amounted to $1,200, and the inventor wanted to pay in stock of the new company. This the lawyer declined at first, but eventually, finding it impossible for Brush to pay in any other way, consented to accept the stock, which he carelessly tossed into his safe and forgot all about it. In due time it was fished out and the lawyer became rich on it. He lives in a palace in Detroit."

This was shown to Mr. G. W. Stockly, formerly president of the Brush Electric Company, who said:

"No such man as Emil Bixel was ever known by me in connection with any stock matter. No such concern as the Brush Electric Light Co. was organized in 1875, as stated. The Telegraph Supply Company was organized in 1875, and its name was afterward changed to The Brush Electric Company. This company never had a small factory in the outskirts of the city, and never had any such struggles as this article intimates. No officer of the company ever offered any stock belonging to the company, to any outsider, at the time, or in the way, or anything like the way described in this article. The next statement, regarding the increase in sixteeen years, of about one hundred to one, is manifestly absurd, and is very far beyond what any investor ever got from his investment in this company. The next statement, regarding the "maiden ladies in Harlem,' is absolutely without foundation. It is the first time that any such statement has been made, although the papers have been full of inventions and funny stories about the Brush Company, and others. Mr. Brush never was a stockholder in the company, and never had anything to do with its business, or its investments or assessments, until after 1885 at least, which was at about the height of the prosperity of the company. There never was a time when the company had any difficulty about money matters such as this article suggests. These yarns are very pleasant to the general reader, who knows nothing whatever about the subject, and they give some occupation, apparently, to the 'penny-a-liners' who get hard up for material. Some of them have a word or item of truth on which to build the story, but this one is absolutely without foundation of any kind whatever."

PRIZE COMPETITION FOR ELECTRIC PLOWS.

The German Agricultural Society has arranged a prize competition for power-driven plows, intended more especially to encourage and develop the application of electrical power to the working of plows and other agricultural implements, says a German contemporary. The society considers that, for many reasons, the application of electricity to agricultural driving promises considerable success, especially on account of the facility which electricity offers for transmitting power to considerable distances. In the trials which will be made by the society non-electrical plows will also be tested, so that a comparison may be made of the relative efficiency of the different systems. The tests will be made with plows only, since it is considered that only small alterations will be required to apply the power to other implements. Special attention will be attached to the conveyance of the arrangements from field to field. A first prize of 3,000 marks and a second prize of 1,000 marks will be given for the best plow driven by any kind of power, and a special prize for the best electrically driven plow. At the trial a piece of heavy and a piece of light land will be assigned to each plow, and the following points will be noted: 1, the time taken for the plowing; 2, the weight of earth moved; 3, the consumption of fuel by the motor; 4, the power consumed between the motor and the plow; 5, the cost of the plowing, including fuel, water, lubricants, attendance, repairs, interest and depreciation.

ELECTRICAL FIGURES OF PHILADELPHIA.

In his annual report on the work of the Philadelphia Electrical Bureau, Chief Walker gives some interesting figures. This city, with 129 square miles, is equipped with 885 fire boxes, 56 of which are in-doors, paid for by private individuals. New York, with but 31 square miles, has 2,500, and Chicago between 2,500 and 3,000. To thoroughly equip the city they should have at least 2,500 signal stations. The average price per arc lamp per night for 1895 was 41.15 cents; for 1896, 35.05, and proposals for 1897 show 33.3 cents, a reduction of $42,862.25. While the number 6,228 now provided for seems to be large, yet, when the great number of streets yet to be lighted is considered, it becomes insignificant. During the year there have been laid 221,834 feet of conduit by the city.

MOTIVE POWER EXHIBITION AT MUNICH, BAV.

The General Industrial Association of Munich, Bavaria, proposes to celebrate its fiftieth anniversary by an exposition of motors and machine tools, to be held in Munich from June 1 to October 10, 1898. The manufacturers of all countries are invited to participate in the exposition, which will have the cooperation of the Polytechnic Association of Bavaria. The object of the exposition is to show the proprietors of small and medium sized factories, as well as all who are engaged in industrial pursuits, everything that can be of service to them in the domain of motors, machine tools and hand tools for the purpose of facilitating and furthering their work and cheapening their products. Safety appliances will be made a special feature, and it is designed to have public lectures on scientific and technical subjects. A medal for excellence in the various departments will be awarded by an international jury.

THE STOCK MARKET

BETTERING CONDITIONS.

A far more hopeful feeling was created last week than had previously existed, by the plan adopted for refunding the bonds of the Lake Shore Railroad, the old rate being 7 per cent. and the new 3½, on a total of $39,000,000. Inquiry has developed the fact that a similar reduction on bonds to be refunded up to 1905, in the higher class of securities, would result in a reduction in the annual fixed charges of $11,779,000, all of which would naturally go to the improvement of the properties or the direct benefit of the stock. Obviously money is decidedly cheaper, and the increased production of gold will long keep it so.

During the past week, 15,666 shares of General Electric were sold at from 36 down to 34¾. There is a good deal of talk about the strength of this stock in New York and Boston, but present conditions do not afford any safe criterion on that score. Of Western Union 8,361 shares were sold, closing at 83, and in Boston, Bell telephone still lingered around 224 to 225. Local lighting and street railway securities throughout the country are quiet, business not being very active in any of them.

"This anniversary number of The Electrical Engineer is a credit to the publishers and a valuable souvenir to its readers." —Detroit Free Press.

EDUCATIONAL

THE RENSSELAER POLYTECHNIC INSTITUTE.

A brochure by Dr. John H. Peck, reprinted from the American University Magazine, gives a most interesting sketch of the work and purpose of the Rensselaer Polytechnic Institute, Troy, N. Y. This institute has a world-wide reputation as a successful school of engineering. The prevailing purpose of the institution is to teach the relations of science and business. Its chief energies have been directed to prepare students for any engineering work. It has, nevertheless, from time to time, expanded its course in chemistry, physics, metallurgy and astronomy, and retained those in geology and mineralogy, botany and modern languages. The institute presents an example of a school of specialized education, with experience extending over a period of three-quarters of a century.

A $30,000 GIFT TO THE STEVENS INSTITUTE OF TECHNOLOGY.

It may be remembered that in connection with the 25th anniversary of the Stevens Institute recently celebrated, President Morton drew attention to the circumstance that while the original endowment and subsequent gifts had supplied all that was necessary for present requirements, the natural and necessary growth of the Institution would make more ample accommodations and a larger revenue essential for an adequate future development of the work which had been so successfully carried on heretofore.

As an object lesson in this direction, he presented on the same occasion to the Trustees some shares of stock likely to appreciate as the year progressed. This suggestion, we learn, has been acted upon by Mrs. E. A. Stevens, widow of the Founder of the Institute, who has transferred to the Trustees two large lots and houses directly adjacent to the Institute grounds, which, while having at present a valuation of about $30,000, have a prospective value many times as great.

OBITUARY

W. H. CULL.

We regret to announce the death of Mr. William H. Cull, the superintendent of the Hudson River Telephone Company, at Albany, N. Y. He was only 43 years of age. He had been actively engaged in electrical work for many years past, and was at one time engaged in electric railway operation. His experience in telephonic work, however, made him a valuable man in that field, to which he returned.

REPORTS OF COMPANIES

COMMERCIAL CABLE PAYS 8 PER CENT.

The statement of the Commercial Cable Company for 1896 was submitted to the shareholders at their annual meeting held last week. The gross earnings, including interest from investments, amounted to $2,019,255, and the total expenses to $842.690. leaving a balance of $1,176,565. The company paid its regular dividend of 7 per cent., together with a bonus of 1 per cent., making 8 per cent. for the year.

NEW YORK AND NEW JERSEY TELEPHONE CO.

The annual meeting of the New York and New Jersey Telephone Company took place last week at the main office of the company in Smith street, Brooklyn. The following directors were elected without opposition: Charles F. Cutler, Alexander Cameron, Joseph P. Davis, Charles A. Nichols, Hugh Kinnard, William D. Sargent, David B. Powell, George

H. Prentiss, Joel C. Clark, Felix Campbell, Edward J. Hall and Henry Sanger Snow. The treasurer's report contained the following items: Gross earnings, $1,554,585.33; expenses, $1,076,854.76; balance on hand over and above operating expenses, $477,730.66; interest and taxes, $107,268.72; new earnings, $370,461.94. Of this, $253,363 was set aside for dividend purposes, leaving a surplus for 1896 of $117,098.94.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Insolated Plants :

POWER PLANT OF ARMOUR INSTITUTE OF TECHNOLOGY.—On account of the demand for lighting and motor service and additional facilities for laboratory work, the above plant was reconstructed. A Hamilton-Corliss single cylinder non-condensing engine, making 73 revolutions per minute is connected to the main countershaft by means of a rope-drive; a 100 k. w., direct current, 6-pole machine at 115 volts furnishes power for shops and laboratories, as well as for incandescent and arc lights. Another dynamo, giving alternating current is used partly for lighting, and partly for laboratory work. Two other engines are connected to dynamos, one of which is used for lighting at light load, the other for experimental purposes only.—"West. Elec.," Feb. 27, '97.

Measurements :

ALTERNATING CURRENT WATT METER.—Illustration of the Hummel system for single phase alternating currents.—"Elektr't,, Feb. 13, '97.

WATT AND THE MEASUREMENT OF POWER.—By W. H. Preece. A paper read at Greenock, on the occasion of the Watt Anniversary Lecture. Reviewing the work of Watt, author dwells principally on the term horse-power, the way it was created, the way it is being used, and expresses the opinion that it will gradually be discarded.—Lond. "Elec. Rev.," Feb. 12, '97.

Miscellaneous :

INFLUENCE OF ELECTRICITY ON PLANT GROWTH.—Short review of the works of Lemström (1887), Specnew (1892), Bonnier (1892), Paulin (1894), Bailey (1896), and Narkewitsch-Jodko (1896), and some of the results.—"Elektr't," Feb. 13, '97.

SOME DIELECTRICS AND THEIR INSULATING PROPERTIES.—By Geo. T. Hanchett. The peculiar action of disruptive discharges on various materials, such as hard rubber and glass, are described.—"Elec. World," Feb. 6, '97.

A REASONABLE METHOD OF TESTING AND RATING SAFETY FUSES.—By F. A. C. Perrine. Author explains that fuses are no protection against a current rush since the time element is a necessary function in order to make the fuse melt. The true method of testing fuse wires, therefore, is to measure the temperature of the wire which is supposed to be protected as the current is increased in the circuit. Kennelly's experiments give for certain cases the maximum temperatures attained by copper wires when continuously carrying current, and the proper current for a given wire should be chosen, such that double its value will not increase the temperature of the wire more than 75 degs. Fahr. We thus have a basis for choosing the proper fuse to protect the wire against overheating.—"Elec. World," Jan. 30, '97.

PROGRESS OF ELECTRICAL SUBWAY WORK.—By Wm. Maver, Jr. Reviewing the gradual development of the subway work since 1888, the author illustrates and describes the principal methods of laying underground wires and cables. The Van Vleck controllable junction box of the N. Y. Edison Elec. Illuminating Co., by means of which the central station or stations are placed in control of the feeders and branches at any desired point receive special attention.—"Elec. World," Jan. 30, '97.

Power Transmission :

PUMPING OIL BY ELECTRICITY.—Colonel J. J. Carter has established a complete electric plant for pumping oil at Sawyer City. Alternating current is used. (Detailed information is not explicit).—"Am. Man.," Feb. 26, '97.

Railways :

ELECTRIC INTERLOCKING THE BLOCK AND MECHANICAL SIGNALS ON RAILWAYS. By F. T. Hollins.—Paper read before the Lond. Inst. of Elec. Eng's, Jan. 28, '97. Brief description of the principal interlocking systems. The following receive special attention: Spagnoletti, Langdon, Evans, Tyer, Blakey and O'Donnell, Sykes.—"Lond. Elec.," Feb. 12, '97.

STREET RAILWAYS AND THE ILLINOIS LEGISLATURE.—Three bills have been introduced in the Legislature of Illinois providing for the regulation of street railways throughout the State. One seeks to create a commission vested with power to regulate running of cars, kinds of cars to be used, manner of heating, and to fix the rates of fare. Also empowered to determine questions similar to those usually determined by the Railway Commissioners in the State of New York. Another bill provides for the extensions of terms of franchise of existing companies, and the third covers the question of taxation.—"West. Elec.," Feb. 27, '97.

COMPARATIVE ECONOMY IN ELECTRIC RAILWAY OPERATIONS. By Charles H. Davis.—An analysis of costs, pointing out the many points of view that have to be taken to determine comparative values of different systems and different machinery.—"Eng'g Mag.," March, '97.

Roentgen Rays:

TIME OF X-RAY EXPOSURES. By Elmer G. Willyoung.—After a reply to an open letter by Dr. Monell, discussing the time of X-ray exposures, author points out four disadvantages of the Tesla coil over the ordinary induction coil, viz.: (1) Tesla coil has at least twice the number of parts—more complex; (2) Tesla coil uses oil—not so cleanly (not necessarily the case); (3) Tesla coil requires an operating spark gap—noisy; (4) Tesla coil produces alternating current—resulting in either two foci, and consequent blurring, or reversal of tubes and consequent blackening.—"Elec. Rev.," March 3, '97.

Telephony, Telegraphy, etc:

TELEGRAPHING WITHOUT WIRES. By H. J. W. Dam.—Author relates an interview with Dr. Bose, explains in popular language the working of telegraphy by induction, and then refers to a new discovery claimed to have been made by a young man by the name of Marconi, who is now working in conjunction with Mr. Preece.—"McClure's Mag.," March, 1897.

INVENTORS' RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 2, 1897.

Alarms and Signals :—

DANGER SIGNAL. D. A. Gordon and B. B. Weir, Cassopolis, Mich., 577,949. Filed Aug. 29, 1895.

Means in connection with a bridge upon which the track is supported whereby signals may be shown to approaching trains should the track become obstructed.

TESTING APPARATUS FOR ELECTRIC AUTOMATIC SYSTEMS. C. Burger, Newton, Mass., 578,077. Filed December 17, 1896.

Adapted for use in buildings equipped with an automatic electric fire alarm system.

ELECTRIC SIGNALLING APPARATUS. B. J. Noyes, Boston. Mass., 578,114. Filed July 11, 1896.

Police signal system in which a "wagon" call is automatically transmitted from the central station to the stable.

RAILWAY SIGNAL. W. P. Hall, Greenwich, Conn., 578,236. Filed November 28, 1892.

Details of construction.

Batteries, Primary :—

COMBINATION BATTERY CELL. H. A. C. Anderson, New York, 578,131. Filed October 30, 1895.

A cell is so constructed that after its effective term of service as a dry cell has expired it may be revivified and used as a wet cell.

Connectors, Conduits and Insulators :—

ELECTRIC CIRCUIT. J. S. Stone, Boston, Mass., 578,275. Filed September 10, 1896.

An electric conductor consisting of a conducting core provided with a longitudinally discontinuous paramagnetic sheath conductively separated from the conducting core. Designed for telephone cable conductor.

Dynamos and Motors :—

COMMUTATOR BRUSH. J. F. Kester and F. C. Atherton, Buffalo, N. Y., 578,016. Filed June 16, 1896.

Consists of a corrugated core and a wire gauze covering surrounding the core.

ELECTRIC MOTOR. H. A. Stock, Millersburg, Pa., 578,069. Filed April 15, 1896.

Embodies a field magnet having poles arranged in two sets in different planes, the two sets being staggered, and an armature having poles arranged in two sets side by side, and not staggered.

DYNAMO ELECTRIC MACHINE AND ELECTRIC MOTOR. C. P. Turner, New York, 578,280. Filed November 25, 1895.

A field magnet for dynamos and electric motors having the faces adjoining the armature formed of chemically pure iron.

Electro-Metallurgy:—

POROUS DIAPHRAGM. H. Blumenberg, Jr., 578,078. Filed November 15, 1895.

A method of making diaphragms, which consists in treating asbestos with acid to remove the metallic salts and toughen it, and finally forcing binding material into the pores of the asbestos under high pressure.

ELECTROLYTICAL APPARATUS. C. P. Turner, New York, 578,171. Filed February 8, 1896.

Employs a transversely partitioned receptacle to hold the ore, having perforated sides for the entrance of the electrolyte.

ANNEALING APPARATUS. C. P. Turner, New York, 578,170. Filed February 8, 1896.

Details of construction.

Lamps and Appurtenances:—

CONVERTIBLE SIGNAL LAMP. C. H. Dressel, New York, 577,079. Filed June 20, 1895.

ALTERNATING CURRENT ARC LAMP. E. R. Knowles, Brooklyn, N. Y., 577,864. Filed August 19, 1896.

Means to obviate "clattering" in alternating arcs, when starting.

ELECTRIC LAMP. M. M. Kohn, Chicago, Ill., 578,107. Filed December 4, 1895.

Bicycle headlight.

ELECTRIC ARC LAMP. A. Guendel, New York, 578,233. Filed July 7, 1896.

Feed mechanism.

Miscellaneous:—

HEAT REGULATOR. W. J. Robinson, Philadelphia, Pa., 577,026. Filed April 16, 1896.

Details of construction.

IGNITING DEVICE. A. Czarnikow, Berlin, Germany, 578,004. Filed February 26, 1896.

An electric gas-lighter which is manipulated some distance from the burner.

ELECTRODE. A. E. Woolf, New York, 578,070. Filed January 13, 1896.

Consists of an exposed thin plate of metal of the platinum group, the plate being comparatively long from end to end, and narrow from its inner attached edge to its outer free edge.

Railways and Appliances:—

TRAIN CONTROLLING DEVICE. C. S. Shea, Milton, Mass., 578,298. Filed October 14, 1896.

Means to electrically operate the air brake lever on a moving train through a track circuit.

TROLLEY POLE CONTROLLER. L. M. Halsey, Brooklyn, N. Y., 577,853. Filed July 20, 1896.

Device for automatically lowering trolley poles when the trolley leaves the wire.

ELECTRICAL CAR LIGHTING. M. Moskowitz, Newark, N. J., 577,872. Filed December 23, 1896.

Current is supplied from dynamo mounted on car truck and belted to car wheel axle.

ELECTRIC RAILWAY. C. Skinner, Chicago, Ill., 577,885. Filed May 27, 1895.

Closed conduit system.

ELECTRIC RAILWAY. S. G. Brosius, Baltimore, Md., and W. B. Upton and J. Colvin, Washington, D. C., 577,912. Filed February 25, 1896.

Plow for conduit system.

TROLLEY CATCHER. T. Holahan, Rochester, N. Y., 577,921. Filed July 11, 1896.

When trolley leaves wire, the upward pull of the trolley cord releases a spring actuated device which draws trolley down by means of a second cord.

APPARATUS FOR REGULATING AND MODIFYING ELECTRIC CIRCUITS. G. F. C. Adam, Hanover, Germany, 578,182. Filed July 7, 1896.

Switching device for electric motor cars, which are run part of the way by current taken from a line wire and part of the way by a current taken from a storage battery.

ELECTRIC RAIL BOND. B. J. Jones, Chicago, Ill., 578,304. Filed April 29, 1896.

Comprises a loop-shaped body portion, formed of a series of strands arranged side by side, and rivet studs secured by casting to the ends of the body portion.

Switches, Cut-Outs, Etc.:—

ELECTRIC SWITCH. W. W. Doty, New York, and J. A. MacKnight, Mt. Vernon, N. Y., 578,139. Filed July 1, 1896.

Comprises a pair of solenoids, bell crank levers operated thereby and adapted to shift the switch point, an automatic switch for controlling the current passing to the respective solenoid, and means for sending a current to the switch.

DOUBLE POLE REVERSING SNAP SWITCH. H. A. Gorn, New York, 577,950. Filed August 6, 1894.

Comprises oppositely arranged plates carrying the circuit terminals and intermediate contact blocks, a rotating shaft carrying connecting contacts, means for operating the shaft manually, and automatic means for completing the movement of the shaft.

Telegraphs:—

MESSAGE RECORDING INSTRUMENT. B. J. Noyes, Boston, Mass., 578,113. Filed June 25, 1896.

Means by which messages may be recorded upon a strip of paper and the time printed upon the face side of the strip of paper close to the message.

ELECTRIC SIGNALING APPARATUS. B. J. Noyes, Boston, Mass., 578,115. Filed July 21, 1896.

Similar to above.

TELEGRAPHY. R. H. Weiny, Arlington, N. J., 578,126. Filed September 4, 1896.

Transmitting and receiving apparatus, in which an indented paper strip is employed in sending.

Telephones:—

AUTOMATIC TELEPHONE CALL DEVICE. E. P. Boland, New York, 577,911. Filed April 6, 1896.

Automatic coin-operated telephone call device.

TELEPHONE CALL REGISTER. W. A. Heckard and D. Ogden, Columbus, Ind., 577,920. Filed June 8, 1896.

A device which, when operated at a telephone exchange, records in the office of a subscriber the telephone number of any person who has called.

TABLE TELEPHONE APPARATUS. L. M. Ericsson, Stockholm, Sweden, 578,006. Filed October 27, 1896.

Comprises a rotary core, pole pieces with horseshoe magnets attached thereto at each end, the magnets extending downwardly from the core and having broadened and spreading base portions to serve as supporting feet.

COMBINED TELEPHONE AND ANNUNCIATOR SYSTEM. J. R. Strong, New York, N. Y., 578,122. Filed July 31, 1896.

A switch consisting of a number of yielding and stationary contacts connected in multiple to two independent battery circuits and an operating and indicating handle adapted to move over the yielding contacts so as to change the circuit relations when depressed and to simultaneously indicate that the circuit change has or has not been effected according to its position.

LEGAL NOTES

THE BRADLEY ALUMINUM PATENTS SUSTAINED.

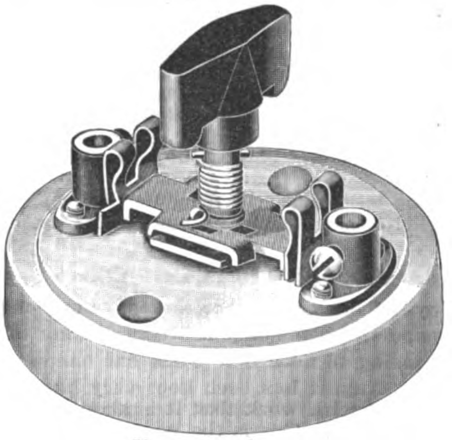
The United States Circuit Court of Appeals has sustained the validity of the Bradley patents for the production of aluminum by the electric fusion. These patents are owned by the Cowles Company, and are numbered 464,933, Dec. 8, 1891; 468,148, Feb. 2, 1892, and 473,866, April 12, 1892. The most important of the above patents is the second, and its principal claim reads as follows:

1. The process of separating or dissociating metals from their highly refractory ores or compounds, non-conductors in an unfused state of which the ores and compounds of aluminum are a type, which consists in fusing the refractory ore or compound progressively by a source of heat concentrated directly upon it rather than by an external furnace, and as it becomes fused effecting electrolysis by passing an electric current there through between terminals which are maintained in circuit with the fused bath, whereby the process is rendered continuous, substantially as set forth.

TRADE NOTES & NOVELTIES

THE HARTFORD SWITCH.

THE switch illustrated herewith is to be known to the trade as the Hartford, being christened after the city of its birth. It is not necessary to introduce the maker, Mr. J. S. Gibbs, as he is well known to the entire electrical fraternity as an inventor and manufacturer of some of the best switches made. In his opinion the Hartford is his crowning effort thus far. Every feature of this new pattern, both mechanical and electrical, has been carefully designed to do the work satisfactorily for the user, and to meet all of the rigid requirements of the rules of the Board of Underwriters. The spring contacts are made of phosphor-bronze. This is considered a decided advantage, as this metal retains its temper permanently and gives full and perfect contact at every movement. The switches turn from left to right, and are actuated by a coiled piano wire spring. The locking and unlocking device is a new combination in switch movements, being accomplished by means of a rack and pinion, which insures a positive but very easy action, without strain or danger of cracking the porcelain base. All parts are substantially made, and are in-



HARTFORD SWITCH.

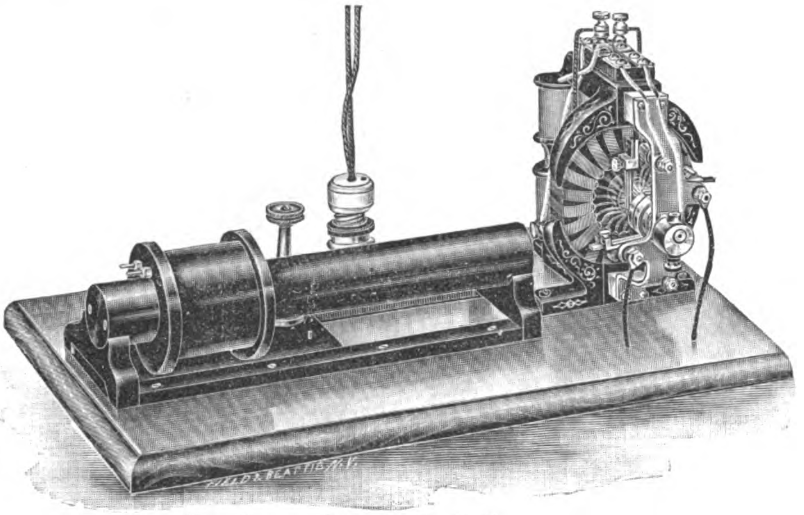
terchangeable, so that if by accident anything should become broken it can be readily replaced. The Hartford switch is made in all of the usual styles and sizes demanded by the trade, and can be bought of all electrical supply dealers. The Conover-Goe Company, Monadnock Building, Chicago, are the general sales agents for the factory.

NEW EDISON DIRECT-CURRENT CAUTERY TRANSFORMER.

THIS apparatus is designed to enable the direct 110 to 120 volt current to be used with absolute safety for electro-cautery work, and will be found of the greatest assistance to those physicians whose offices are equipped with this current. It is also suitable for hospital work, as nearly all of the most prominent institutions are lighted by the Edison direct low tension system.

It consists of a 120 volt Edison motor, the armature shaft of which is provided with two collecting rings which are connected to the armature at points diametrically opposed.

The current taken from these collecting rings, which is now of an alternating character, is led into the primary circuit of the transformer, shown on the left of the cut. The primary circuit is composed of a number of turns of fine insulated copper wire, wound on a core of annealed iron wires, the whole being inclosed in a thin cylindrical shell of hard rubber, which is supported by a hard rubber standard at each end. The secondary coil, composed of a few turns of thick wire, is wound on a hollow hard rubber spool operated by a rack and pinion movement and sliding over the primary coil. The terminals of ~~the secondary~~ coil are brought out to two-pin attachments mounted on one head of the coil, and the cautery cords are connected thereto by split socket connections. On moving the secondary coil to the right, the current is increased, and vice versa. The apparatus is mounted on a highly polished oak base, and is provided with an attachment plug and ten feet of flexible cord for connecting the instrument to the mains.



NEW EDISON CAUTERY D. C. TRANSFORMER.

The apparatus is manufactured by the Edison Manufacturing Company, 110 East 23d street, New York City.

BOSSERT ELECTRIC CO.

In these days of business depression, says one of the Utica, N. Y., newspapers, when many are complaining of the hard times, it is pleasing to note that Utica has one establishment which since last August has been kept very busy, and which is now so crowded with work that it is about to build a new and much larger plant. This is the Bossert Electric Construction Company. Mr. Bossert brought his inventions to the notice of the Utica Chamber of Commerce, and shortly afterward the company was organized, the members being H. P. Crouse, William F. Bossert, Hon. Frank Sang and Seth C. Adams. The company established its plant at 40 Broadway and put in heavy machinery. So popular has its product proved that it is now obliged to enlarge its plant. The company manufactures its well known wall outlet and switch boxes, and also steel clad, slate lined panel and junction boxes and switch board. The superiority of these boxes over others lies in the fact that they are drawn out of steel and are therefore far more valuable than boxes of cast iron, although they are made more rapidly. (See The Electrical Engineer, Feb. 10.)

Architect Constable has nearly perfected plants for the new building, which will be erected in the western part of the city. It will be 48x88 feet on the ground, two stories high, prepared for three, and will be built of heavy timber work. There will be heavy girders of Georgia pine eight feet apart, over which a four-inch floor will be laid. The floors will be supported by heavy posts of Norway pine. There will be three lines of shafting on the first floor, which will be occupied by heavy machinery. Heavy stone foundations will be built for the presses which stamp out the boxes, the largest press giving a blow equal to 84 tons' weight. On the first floor also will be the office, 14x15, a private office, 10x15, and opposite these will be a large store room. The lighter machinery will be on the second floor. Near the building, separated by an alley, will be three brick buildings. They will be an enameling room, 20x21 feet, engine room, 15x10 feet, and boiler room, 15x21 feet, with coal shed attached. All the buildings will be lighted by electricity, connected with city water, and the roofs will be of asphalt and gravel. The new plant when completed will enable the company to largely increase its output. This evidence of its prosperity is very gratifying.

BALL ENGINES.

The Hammond Building of Detroit, Mich., will in the future supply its own electric lighting. The dynamos were furnished by the General Electric Company and the engines by the Ball Engine Company, Erie, Pa.

The Harper Hospital of Detroit, Mich., has recently put in its own electric plant, consisting of two engines built by the Ball Engine Company, Erie, Pa., direct connected to General Electric Company dynamos.

ANCHOR SNAP SWITCHES.

The Electric Appliance Company are just distributing to the trade a catalogue containing a complete line of Anchor snap switches. This is probably the most complete catalogue of snap switches that has been published, and includes a number of new applications of the device; also a complete line of dial or indicating switches. The Electric Appliance Company have prepared a special trade discount sheet for this catalogue, which quotes up-to-date prices on the goods listed. They will be glad to receive inquiries for the catalogue.

I-T-E CIRCUIT BREAKERS.

In the recent disastrous fire which destroyed entirely the principal power house of the Union Traction Company, Philadelphia, on the night of March 3, there were in use a number of I-T-E circuit breakers, as well as circuit breakers of other makes and types. While the engines were still playing upon the flames, Mr. Charles Hewitt, the chief electrician of the Union Traction Company, placed himself in communication with the Cutter Electrical and Manufacturing Company, of that city, and ordered for immediate delivery, one hundred and sixty-five I-T-E circuit breakers. This order was provisional upon prompt delivery, as required by the Traction Company. Inside of twenty-four hours, 116 of these circuit breakers were delivered to the Traction Company.

It would seem that comment upon the merits of the I-T-E circuit breaker, and the size of the Cutter Company's business, which would enable it to fill this order—one of the largest ever placed at one time for circuit breakers—is unnecessary. The fact that standard switchboard types were ordered, made it possible for the entire order, practically, to be filled out of stock.

THE BULLOCK ELECTRIC MFG. CO.

ONE of the most important of the recent moves in the field of electric power and motor manufacture has already been noted, briefly in these columns, namely, the change in style of the old Card Electric Motor and Dynamo Company of Cincinnati, and its development of new plans for handling a business whose magnitude is quite surprising. The Bullock Electric Manufacturing Company, which is the new designation, is simply expressive of the actual conditions of control, Mr. George Bullock in a sense being the company so far as ownership goes, and being also its president. The directors chosen at the recent annual meeting are: Messrs. G. Bullock, J. W. Bullock, G. N. Stone, P. R. Mitchell, J. S. Neave, and G. W. Wilshire, one of whom, Mr J. S. Neave, has been elected vice-president and secretary.

With the new and shorter name the Bullock Company is also free from the confusion existing owing to the similarity of its name with that of another corporation, and the change is generally welcomed, if no other reason existed. As a matter of fact, however, from this time out a more active and aggressive policy will prevail, and special plans have been made to push into the fields where an obviously brisk demand awaits the Bullock dynamos and motors. A separate but closely allied company for the selling and engineering work in the East has been organized by Mr. Bullock and his energetic young coadjutor, Mr. R. T. Lozier, who for some time past has been the company's representative in Eastern territory. In other words, the parent company will restrict itself to the manufacture of the apparatus. The Bullock Electric Company, as the selling organization is called, has its main offices in a fine suite on the 16th floor of the new St. Paul Building, Broadway and Postoffice Square, New York, with branches at 8 Oliver street, Boston, and 665 Bourse Building, Philadelphia. Agencies have also been established in Chicago, St. Louis, Louisville, Atlanta and Spokane. In England, the Bullock interests are represented by Bergtheil & Young, London. The company is experiencing a good inquiry for its machinery for export, as well as at home.

MISSOURI TELEPHONE MANUFACTURING COMPANY.

The illustrated catalogue of the Missouri Telephone Manufacturing Company, 917-919 Market street, St. Louis, Mo., covers every detail of the switchboard, telephonic, and electrical appliances manufactured by the firm, whose factory is fully equipped to supply everything needed in connection with a first-class telephone exchange. One of the specialties of the company is a single plug switchboard, which they claim gives the most rapid service of any switchboard on the market. It is simple in operation; gives no chance for induction, or cross talk, and can be added to by sections. It is equipped for both metallic circuit and single line systems, and can readily be changed from one to the other. Other appliances to which the company give special attention are a new combination switchboard, double-plug, 100-number switchboard, central station switchboard lightning arrester and distributing board, improved forms of transmitters, receivers, magneto signal bells, and batteries, and a full line of construction material, including telephone and telegraph cables, poles, wire, insulators, tools, etc.

ASSOCIATED MANUFACTURERS' TRADE "SPECIAL"

"The Great White Special," consisting of an entire train of Pullman cars, painted white and gold, is the attractive stock in trade of the organizers of the Associated Manufacturers' Trade "Special," who have their office at 714 Havemeyer Building, New York. They propose to fill the train with exhibits of leading manufactured products, and make a tour of the country. The route has been advisedly selected, and will embrace cities of 10,000 population up to 75,000, as stopping places of that class are found to present the most fertile field for an exhibition of this kind.

A fixed price of $750 is charged each exhibitor for the six months over which the trip is to extend. Facilities will be given for establishing agencies and for selling from samples in the towns visited. The representative of each exhibitor, who travels on the train, will be able to arrange to meet any local merchant, show him his samples, and do business. A concern which has no representative on the train can arrange to have any merchant in the cities visited meet the train en route.

The "Special" will be open to the merchants of any city up to noon, and the public will be admitted during the afternoon and evening. The train will consist of twelve cars (ten exhibition cars, a hotel car, and a baggage car), all Pullman vestibuled, each sixty feet long, and equipped with Westinghouse air-brakes and automatic couplers. The entire train will be lighted inside and out by electricity, and heated by steam.

WORTHINGTON COOLING TOWER.

A special catalogue has been published by Henry R. Worthington, New York, on the applications of the Worthington cooling tower. This apparatus is the embodiment of an invention the value of which will be at once recognized by engineers and owners of plants requiring the removal or absorption of large quantities of heat generated during any process. Such absorption is particularly necessary in the condensation of steam from steam engines, and the condensation of ammonia in connection with refrigerating plants; and in these and many other kindred processes the cooling tower is the most modern and efficient means of saving the water usually allowed to run to waste after it has passed over the various condensers and coolers. It is proved by actual service that this device will effect an economy of 85 to 95 per cent. in refrigerating and ice making plants and in locations where heat has to be absorbed, and it has been found especially serviceable where water is scarce.

The catalogue is fully illustrated and shows the application of the cooling tower to various types of steam engines, etc.

ONGLEY ELECTRIC CO.

P. Tecumseh Sherman has been appointed receiver of the property in this State of the Ongley Electric Company, by Judge Pryor of the New York Supreme Court, on the application of John S. Maben, who was appointed receiver in New Jersey, on January 8, 1895. The assets in that State were small, and Mr. Maben was unable to get possession of the books of record or any of the papers of the company. He believes there are assets in New York City consisting of notes aggregating $37,500, which are under attachment, and judgment has been rendered on the attachment for $13,773, which would leave a surplus for the company if the notes are paid in full. To get the surplus is the object for which Mr. Sherman was appointed receiver. His bond was fixed at $10,000.

METROPOLITAN ELECTRIC CO.

The Metropolitan Electric Company, of Chicago, have been given the Western agency for the full line of adjustable incandescent lamp holders, made by White & Co., of Worcester, Mass. These holders are specially adapted for factory, mill and machine shop work, where the operator must have good light. They are simple in construction, strong and durable, and do their work perfectly. They are made in various forms to suit all classes of work. They allow the lamp to be shifted, and no attention is paid to the fastenings or joints, as they are constructed so as to be adjustable in every conceivable position. They pay for themselves easily in the saving of the workman's time, as well as secure better results on account of the perfect lighting. Among the many who are using these holders and recommend them are R. Hoe & Co., New York City; Washburn & Moen Manufacturing Company., Westinghouse Machine Company and Wagner Palace Car Company.

ADVERTISERS' HINTS

JOHN WEDDERBURN & COMPANY, patent attorneys of Washington, D. C., are now offering $1,800 in prizes for new ideas in patentable inventions.

INTERIOR CONDUIT AND INSULATION COMPANY, 527 West Thirty-fourth street, New York, report the new styles of Lundell fan motors for 1897 to be ready.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, show a cut in their "ad" of one of their most recent installations.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, call attention to their catalogue of Anchor switches.

THE LE VALLEY VITAE BRUSH COMPANY are advertising the Vitae commutator brushes, which they are extensively manufacturing.

THE DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., have some new designs in their well known fans for any current except alternating.

THE ROYAL ELECTRIC COMPANY mention some of the advantageous features of their apparatus and guarantee their armatures for two years.

NEW YORK NOTES.

REFRIGERATION.—A very interesting pamphlet on the subject of refrigeration has been issued by Westinghouse, Church, Kerr & Co., Havemeyer Building, New York City, and should be found useful in a great many fields of industry. A great deal of practical information is given on the character and use of refrigerating apparatus. A copy of this illustrated pamphlet will be sent on application, and we recommend our readers to get one.

GOLDMARK & WALLACE, 29 Chambers street, New York, are noting an improved business in dynamo brushes, and conclude that people are working longer hours. They have also issued a neat catalogue of their fan and fan motors, one of the best on the market, and will be glad to mail a copy to any address on application.

THE KENNEDY VALVE MANUFACTURING COMPANY, 75 John street, New York, have just issued a fine catalogue of their large line of valves. Their goods are in extensive use among electric plants. The company will take pleasure in mailing catalogue to any address on application.

LOCKPORT, N. Y.—The Holly Manufacturing Company is contemplating putting in an electric plant of its own. The company may submit a bid, it is said, for lighting the city of Lockport.

THE KENDALL CARRIAGE COMPANY, to build electrically propelled vehicles, was incorporated last week at Camden, N. J.

THE ELECTRIC ENGINEERING AND SUPPLY COMPANY, of Syracuse, N. Y., have elected officers as follows: H. C. Hodgkins, president; H. R. Sanderson, vice-president; H. A. May, secretary and treasurer. These are also the directors, with J. E. Zeublin and J. V. Clark.

PROCTOR-RAYMOND MANUFACTURING COMPANY, 444 Niagara street, Buffalo, N. Y., which was incorporated last month, with a capital stock of $30,000, has since then been very busy in increasing its capacity, and putting in stock preparatory to manufacturing on a larger scale than ever, in the line of bells, annunciators, push buttons, etc. They confine the sale of their goods almost entirely to the wholesale trade.

THE AJAX ARC LAMP COMPANY, of New York City, has been formed with a capital stock of $100,000. The directors are B. H. Pomeroy, E. Woltmann, L. E. Shinn, D. H. Gildersleeve, A. Kirkham, J. Lowenthal and C. S. Van Nuis.

THE EASTERN ELECTRICAL SUPPLY COMPANY has opened its headquarters at 26 Cortlandt street, and welcomes all old friends. Its officers are B. H. Ellis, president and manager; C. P. Scott, vice-president and secretary, and C. I. Hills, treasurer. An experience ranging over ten years makes these gentlemen experts in their line, and they will be glad to quote prices on all supplies and fill any orders at lowest prices.

WESTERN NOTES

THE OTTUMWA PRESS, illustrated and described in our pages last week, is made by the Ottumwa Iron Works, of Ottumwa, Iowa., who will be glad to receive inquiries on the subject.

A PAN-AMERICAN EXPOSITION is proposed for Niagara Falls, and Cayuga Island, at La Salle, has been bought for the purpose by the promoters, at whose head is Capt. J. M. Brinker, of the Gorge Electric Railroad.

NEW ENGLAND NOTES

SHAWMUT FUSE WIRE COMPANY, 93 Federal street, Boston, call attention to their new 500-volt, quick-break switch, which they say is the only one approved by the underwriters throughout New England, and the only one coming within the recent specifications issued by the City of Boston.

THE ELEKTRON MANUFACTURING COMPANY have moved their office to 143 Federal street, Boston, Mass.

SOUTHERN NOTES.

THOMAS & HUNTER, electrical engineers and contractors, of Richmond, Va., have been compelled by pressure of business to open a branch office at Charleston, S. C. They have about completed a telephone exchange of 350 subscribers at Augusta, Ga., and are putting in an exchange of 800 subscribers at Charleston, S. C., to be ready by May 1.

The Electrical Engineer.

Vol. XXIII. MARCH 17, 1897. No. 463.

TELEPHONY AND TELEGRAPHY

THE NEW DEY STREET TELEPHONE BUILDING, NEW YORK CITY.

BY HERBERT LAWS WEBB.

WHEN the first distinctively telephone building in this city was erected, at 18 Cortlandt street, in 1888, it was thought that its six spacious floors of offices would provide accommodation for a long time to come for the various departments of the different telephone companies that became its tenants. The growth of the telephone business, however, has been so rapid and so sustained that within a few years it became necessary to close the doors to outside tenants, of whom at first there were quite a number, so as to make room for the ever-expanding departments of the telephone companies and latterly, since the capacity of a building cannot be increased like that of a switchboard, various of these have had to be moved into other buildings to make space for the expansion of those branches which it is especially desirable to keep under one roof. But as there is no limit at present in sight to the growth of the telephone business the question of securing larger office quarters in order to keep the working forces together and in close touch with each other had to be solved sooner or later and the solution has been found in the erection of the Dey street building.

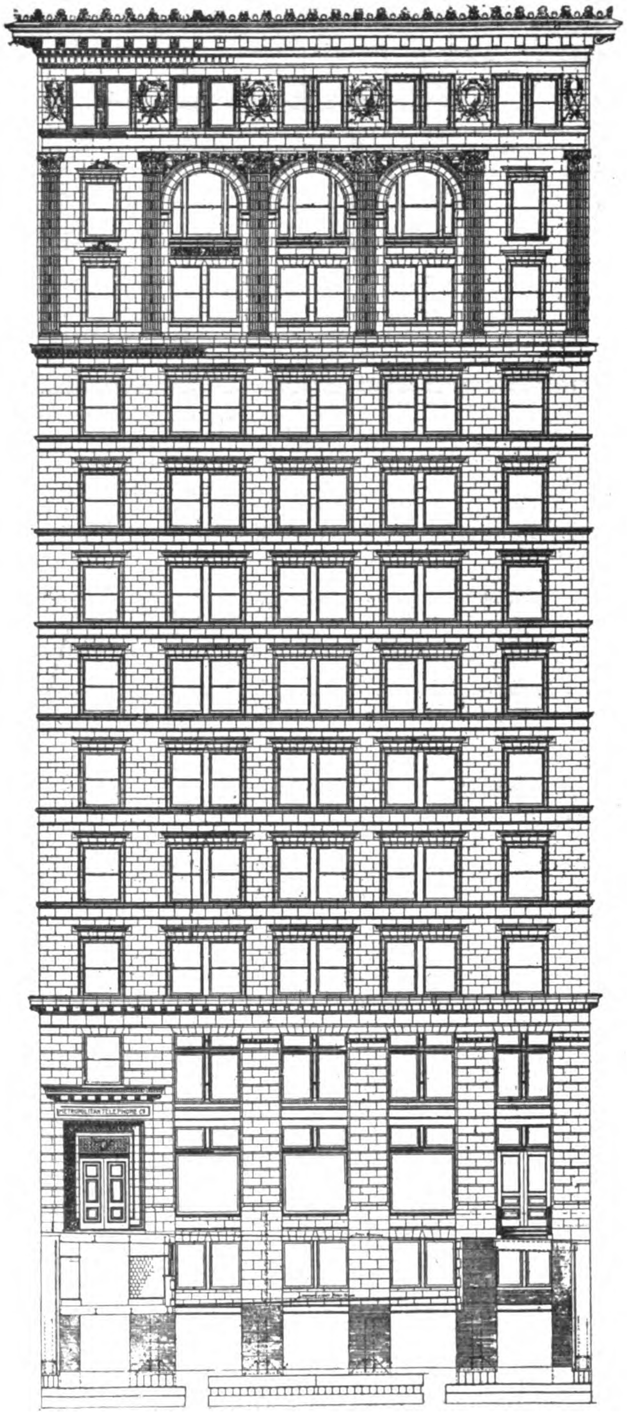
The site of the new building is immediately in the rear of the present telephone building, but does not exactly correspond, beginning one lot west of the site of the Cortlandt street building. One of the old buildings that formerly occupied the site was for a long time used by the New York Telephone Company for the accommodation of its supply, maintenance and construction departments, which were moved last winter, when the builders were ready to tear down the old structures, to quarters in Dutch street.

The new telephone building is remarkable in several ways. As a building proper it has attracted much attention by the elegance of its architecture and the beautiful color and texture of the material used in the external decoration. In point of electrical equipment it is a striking refutation of the old proverb relating to footwear, for the building, which will be exclusively occupied by electrical companies, is provided with the most complete power and electric plant and systems of wiring for lighting and telephone work to be found in New York City. Finally, the building, although on a different street and of a different style of architecture, practically forms an enlargement of the present building, as the rear abuts on the west wing of 18 Cortlandt street, the floors are on the same level and the two buildings connect at each floor—that is, as long as the floors of the old building last out, for it has eight only to the present twelve and future sixteen of the new one.

THE BUILDING PROPER.

The Dey street building is of the steel cage construction, resting on a foundation of grillage beams which practically cover the entire lot. The front of the building measures 72 feet and the depth something over 90 feet. The shape of the floor plan is that of a T, the stem, with a court on either side lined with white enamel brick, running back to the end of the west wing of the Cortlandt street building. The building is designed for sixteen stories, twelve of which, besides the basement and sub-basement, have been carried out at present, the intention being to eventually increase the building to its full capacity by adding the four other stories at a later date. In this the architect, Mr. Cyrus L. W. Eidlitz, who has designed all the telephone buildings in New York, seems to have taken a wrinkle from the telephone switchboard, for the arrangement of a large building, so that its original capacity may be increased by some 30 per cent. as soon as desired, is not an every-day affair.

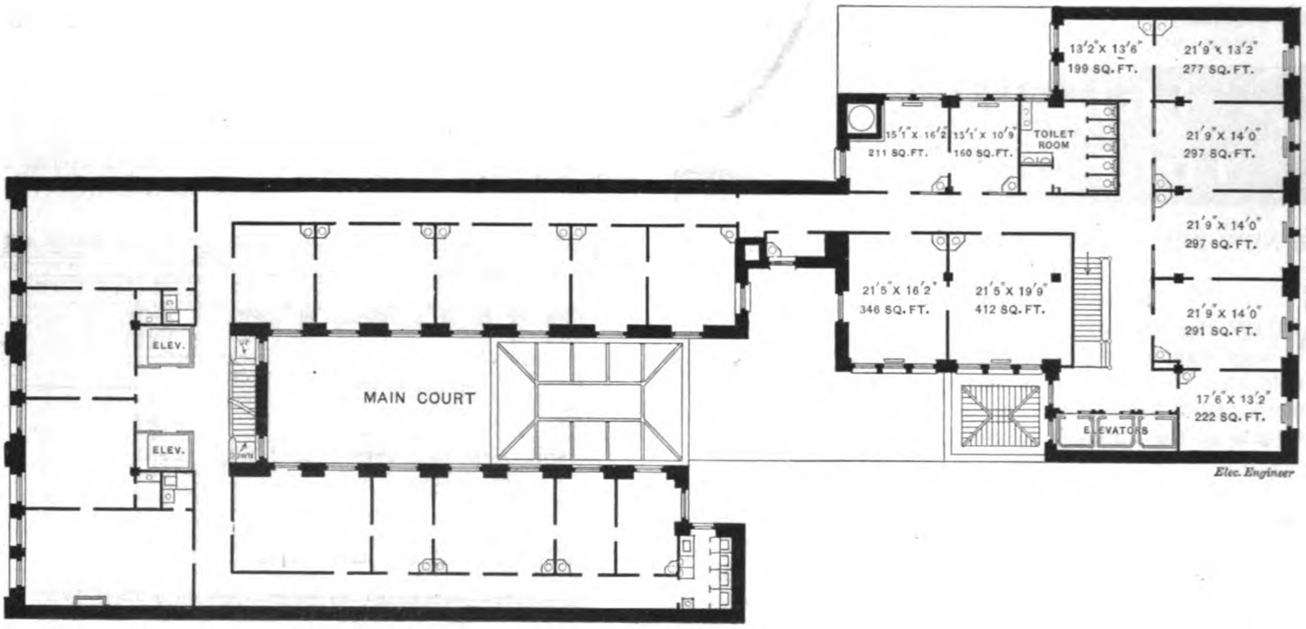
The distinctive feature of the building proper is the method adopted by the architect in carrying out the front, which from the basement to the roof is entirely of terra cotta, backed with brick work in the usual way. The style of architecture is classic in detail, resulting in a general simplicity and distinction of tone which are in the best of good taste and admirably suited to the character of the building. The terra cotta is heavily glazed; its general color is of a buff or cream tint, with such slight variations in shade as are found in burnt clays and which add interest to the color effect of the whole. The entire front has that warm ivory tone so much admired in ancient marble buildings, and this admirable effect has been so much noticed and commented on by those who have watched the construction of the building that general curiosity has been aroused as to the nature of the material used,



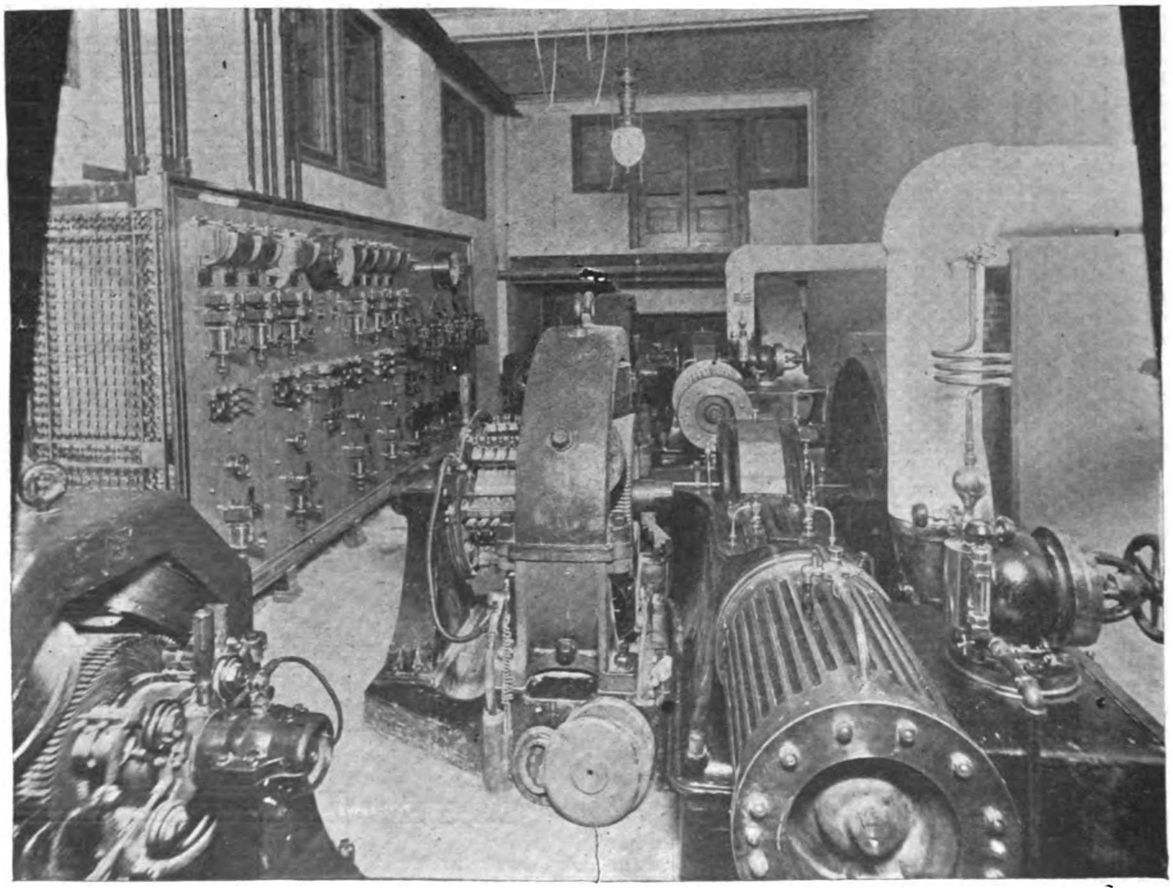
DEY STREET TELEPHONE BUILDING, FRONT ELEVATION.

most of the uninitiated believing it to be stone. The extreme hardness of the terra cotta justifies the impression of the casual observer who should take it for stone, as it is harder and more durable than many kinds of stone, and these qualities, together with the high glaze given to it, make it permanent and prevent staining from soot or the ravages of the weather. Naturally the use of terra cotta has necessitated a different distribution of joints than would have been the case with stone, as it is not practicable to manufacture the material in as large pieces as stone or granite can be obtained in, but the treatment of the joints has been skillfully handled as a part of the general design and in nowise detracts from the harmony of the architecture. The two lower stories are treated as a base and the five succeeding stories as a shaft, which is crowned by more richly ornamented features, with a heavy projecting cornice at the top.

The building is thoroughly fireproof and all parts have been scrupulously carried out in accordance with the latest methods of fireproof construction. The terra cotta is that of the Perth Amboy Terra Cotta Company.



Floor-Plan, Dey Street and Cortlandt Street Telephone Buildings.

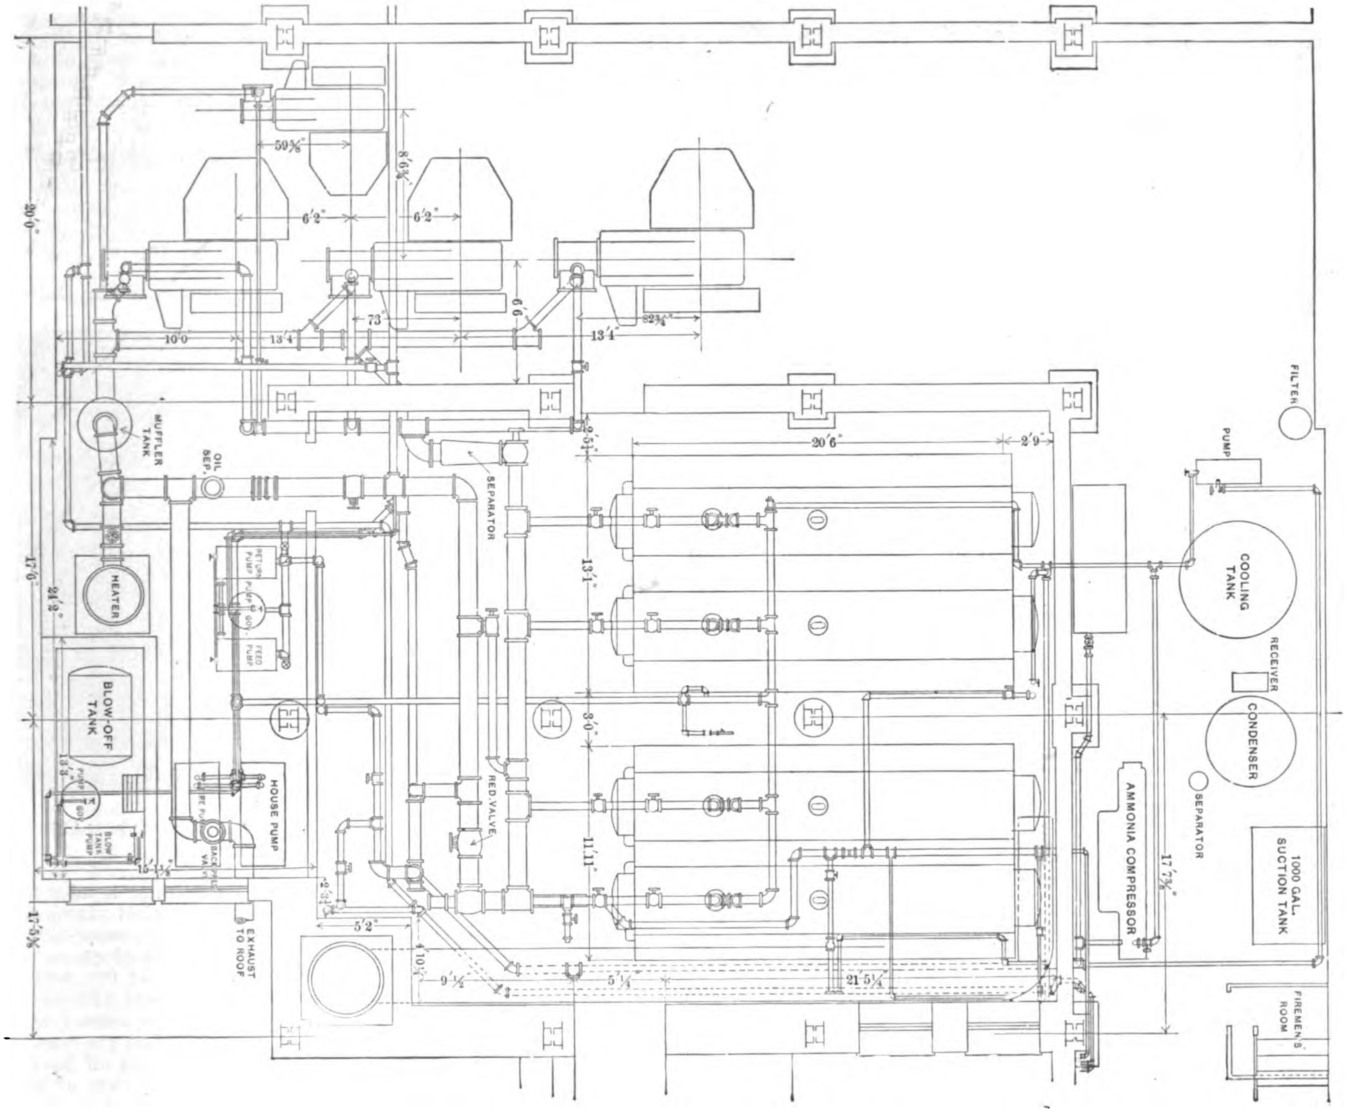


Dey Street Telephone Building.—General View of Engine Room. Western Electric Dynamos, Ball & Wood Engines.

THE POWER PLANT.

The power plant and the wiring of the building for lighting and telephone communication have been laid out by the engineering department of the New York Telephone Company, Mr. Edward P. Decker, formerly of Mr. J. J. Carty's staff, having drawn the specifications and supervised the work of installing the plant, wiring, fittings and fixtures from start to finish. Since Mr. Decker took charge of this work he has been appointed engineer in charge of the power and lighting plants of all the New York Telephone Company's buildings.

The power plant will furnish current for both the new and the old building and the present plant at 18 Cortlandt street will be done away with and the space otherwise made use of. The Dey street plant consists of a general central station to supply the two buildings with light, power, elevator service, heat, hot water and ice water, and its arrangement has given ample scope to its designer to turn out an up-to-date system; an opportunity which Mr. Decker has availed himself of in a manner that would do abundant credit to an engineer of far longer experience. The contractors who have carried out the work are the Western Electric Company, the Sprague Electric Elevator Company, Baker, Smith & Co., and Byrne & Murphy. The refrigerating machine and drinking water system were supplied by G. F. Blake Manufacturing Company.



The New Telephone Building, New York.—Arrangement of Boilers, Steam Piping, Refrigerating Plant, etc.—Plan.

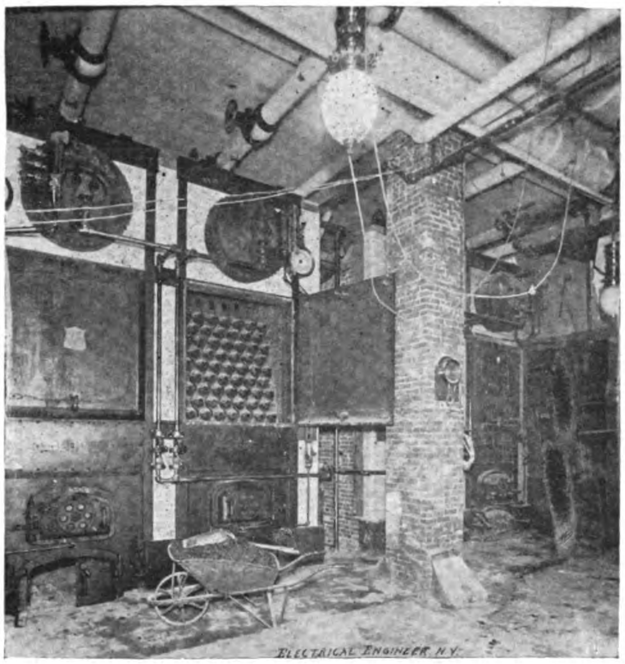
The plant consists of four boilers and four direct-connected units, three of 75-kilowatt capacity and one of 25-kilowatt. One of the 75-kilowatt units is to be used for running the three Sprague electric elevators with which the new building is provided; the other two and the 25-kilowatt unit will be used for the lighting and power work of the two buildings. The various units, although designed to be normally used as described, are so arranged and connected, as will be shown later, that they are completely interchangeable; any unit may be used either for the elevator or for the lighting circuits, and any one unit or all together may be used to supply both circuits simultaneously.

The boilers are Babcock & Wilcox wrought steel sectional type, arranged in two batteries of two each. They are suspended at each end from wrought iron supporting frames, independent of the setting, to allow of contraction and expansion without straining either boiler or brickwork. This arrangement also allows of repairing or renewing the brickwork without disturbing the boilers or their connections.

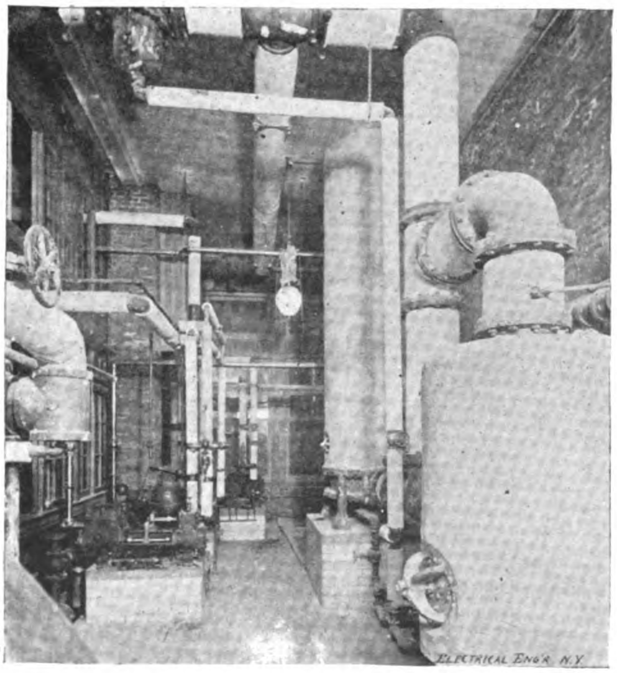
Instead of the usual brick wall at the back of the boilers wrought iron folding doors are fitted, permitting easy access to the entire rear end of each boiler for inspection and cleaning. The front of the battery is of ornamental design, the framework being of heavy wrought iron channel and I-beams, filled in with white enamel brick; the frame is fitted with large doors to give access to the handhole plates and front headers. The heating surface of each boiler consists of a steam and water drum 36 inches in diameter by 21 feet 3 inches long, placed above and connecting with a set of seven sections of tubes in two boilers, and with a set of six sections of tubes in the other two; each section of tubes contains nine tubes 18 feet long and 4 inches in diameter. The total heating surface is 5,208 square feet and the total grate surface 115½ square feet. The boilers are designed for a working pressure of 200 pounds and have been tested in place and made tight at 300 pounds, but the actual working pressure at present will be 100 pounds.

ENGINES AND DYNAMOS.

The engine and generator plant consists of four Ball & Wood single cylinder, high-speed engines directly connected to four Western Electric compound-wound multipolar dynamos, three



Dey Street Telephone Building.—Boiler Room.



Dey Street Telephone Building.—Pump Room; Showing Muffling Drum and Feed Water Heater.

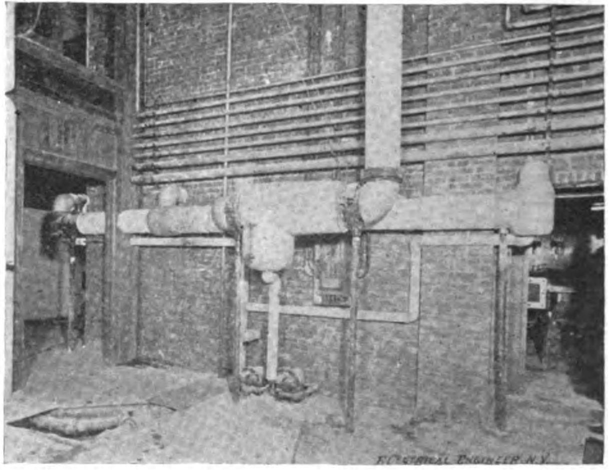
of 75-kilowatt capacity and one of 25 kilowatt. One 75-kilowatt unit is specially designed to run the electric elevators and the engine is slightly larger and with a heavier fly-wheel than those of the other two 75-kilowatt sets, which, together with the 25 kilowatt set, are for the lighting of the two buildings. The 75-kilowatt sets will be driven at 275 revolutions per minute and the 25-kilowatt set at 300 revolutions. The generators are designed to furnish a pressure of 120 volts at these speeds and at normal load must deliver at least 8 amperes per kilowatt capacity. The specifications require a commercial efficiency at full load of not less than 90 per cent. for the 75-kilowatt machine and not less than 86.5 per cent. for the 25-kilowatt machine, and at half load of not less than 88 per cent. and 83.9 per cent., respectively. When working continuously at full load the temperature of the field and armature windings is not to exceed 60 degs. Fahr., and that of the commutator is not to exceed 80 degs. Fahr. above that of the surrounding air.

Each dynamo is to be capable of carrying an overload of 30 per cent. for a period of one hour without sparking or injurious heating. The machines must operate from no load to 30 per cent. overload without the brushes being shifted and without sparking, and to 50 per cent. overload without flashing or injurious sparking. The four machines must operate perfectly when running in multiple.

ENGINE AND BOILER ROOMS.

The four steam and electric units are set in a row in a spacious and lofty engine room in the sub-basement immediately opposite the bottom of the elevator shaft. The engine room, containing the engines and dynamos, elevator motors and switchboard, measures 64 feet by 19 feet and is 20 feet high. Immediately adjacent, and practically forming one department with the engine room—as the brick partition between the two has, besides the steam pipe openings, a large doorway, throwing the two departments together—is the boiler room, which measures 40 feet by 33 feet, containing the boilers and furnaces, feed-water heater, pumps, oil pump and filter, etc. A praiseworthy feature of this department is a small gallery containing a toilet room and shower bath for the use of the engineer in charge of running the plant.

In close proximity to the hot-water plant is installed an outfit for the very opposite purpose—a Blake refrigeratitng machine with storage tanks for containing ice water. From these tanks ice water will be pumped to every floor of the two buildings where it will be continually on tap at fountains placed in the halls.



Dey Street Telephone Building.—Decker Steam-Drying Device.

A device introduced by Mr. Decker to secure the delivery to the engines of perfectly dry steam is a large header main provided with a drain to carry off the water that may collect in it. The main steam supply from the boilers passes through a separator and then feeds into this pipe; the pipes running to the engines branch off from the upper part of it. Any water carried over from the boilers with the steam and not collected in the separator will naturally tend to collect at the bottom of the pipe or header main and will find its way into two pockets at the ends whence it will be carried off by drain pipes protected by a trap operated by the collection of water in the drain pipes. A grease extractor is inserted in the exhaust pipe to cleanse the steam passing through the heating system of particles of grease.

The house pumps are controlled by automatic regulating valves which stop the pumps when the tank is filled and restart them when the water falls to a certain height. The pumping plant is separated from the rest of the boiler room by a glass partition which permits the engineer of the plant to keep a watchful eye on the operation of the pumps while it protects them from the dirt and dust incident to a boiler room. The pumps are of Worthington make.

The ventilation of the engine and boiler room has been well attended to by the placing of three large ventilating flues in the upper part of the rooms connecting directly with the air-space surrounding the main boiler flue. This arrangement will give a permanent and sufficiently powerful draught to ensure efficient ventilation without the use of mechanical blowers.

The brick partition which partially shuts off the boiler room from the engine room is double, with a large air-space in the middle, in order to prevent the heat of the furnaces and boilers from making things too warm in the engine and dynamo room; the opening in the partition is at the end of the room furthest away from the boilers. The engine and boiler rooms are lighted by arc lamps.

MACHINE FOUNDATIONS.

In the installation of the power plant every precaution has been taken to guard against vibration. The foundations of the engines, dynamos and elevator machinery have been combined into a single mass, consisting of a solid prism of concrete, three feet thick, which extends nearly the entire length of the engine room and has been so planned that it in no part touches the foundations of the building. Where this concrete foundation overlaps the grillage beam piers that support the columns of the building the overlapping parts are supported by I-beams bridging over the grillage beam piers without touching them, thus leaving an air space between the machine and building foundations. In this way an absolutely separate foundation for the engines and dynamos has been obtained and vibration from them cannot well be communicated to the building. To reduce the possibility of vibration being transmitted from the exhaust pipes the exhaust from each engine is connected to the main exhaust pipe at an angle of 45 degrees instead of at right angles, as is the common practice; the main exhaust pipe has been much increased over the standard practice and is connected to a large muffling drum provided with screens to collect the water before the steam passes to the feed water heater and to the steam heating system.

The steam heating system is arranged so that it may be supplied either from the exhaust steam or direct from the boilers, and the entire plant may at any time be connected with the New York Steam Company's supply, so that even in the unlikely event of all the boilers being put out of service at the same time the entire plant of engines and dynamos, heating systems, etc., could still be operated without interruption.

THE SWITCHBOARD.

The switchboard is a notable piece of work, of which the electrical contractors have every right to be proud. It is of pink Tennessee marble, two inches thick, and measures 19 feet long by 7 feet 10 inches high, and stands 8 inches above the floor. It is enclosed in a bronze frame and flanked with bronze wire doors which close the space between the board and the wall. About a third of the space of the switchboard at the right hand end is occupied by the pilot motors, rheostats, switches and instruments governing the operation or the elevator plant. The rest of the board carries the switches, circuit breakers, fuses, rheostats and measuring instruments relating to the generators and lighting feeders. At the rear of the switchboard run two sets of bus bars, one of 2,000 amperes capacity for the lighting system and one of 1,000 amperes capacity for the elevator system. The two sets of bus bars are so arranged that they may be connected together and operated from any one or all of the machines, or either set may be independently operated from any machine or combination of machines. The generators are connected through fuses and magnetic circuit breakers to double-throw switches by means of which they may be thrown on to either the lighting or the elevator bus-bars. The field rheostats, of the Carpenter enamel type, are mounted at the back of the switchboard, their controlling handles only projecting through in front.

The arrangement of measuring instruments is very complete and affords most perfect control of all the circuits. The adoption of the Van Vleck edgewise system of instruments has added much to the appearance of the board and has made it possible to install the required amount of apparatus in much less space than is usually required. The lighting bus bars are provided with an ammeter reading up to 2,000 amperes and a voltmeter reading up to 125 volts, and with a Thomson recording wattmeter; the elevator bus bars have an ammeter reading up to 1,000 amperes, a voltmeter reading up to 125 volts and a recording wattmeter. On the lighting section there is also a Weston illuminated dial ground detector.

At the center of the lighting section of the switchboard are mounted four ammeters, three reading up to 750 amperes and one reading up to 300 amperes, for the four generators. On the lighting section of the switchboard is also mounted a differential voltmeter, reading up to 130 volts, which is connected to a double-pole multiple-throw switch so that it may be used to register the voltage of any single machine or pair of bus bars. All the measuring instruments except the Thomson recording wattmeters are of the Weston type.

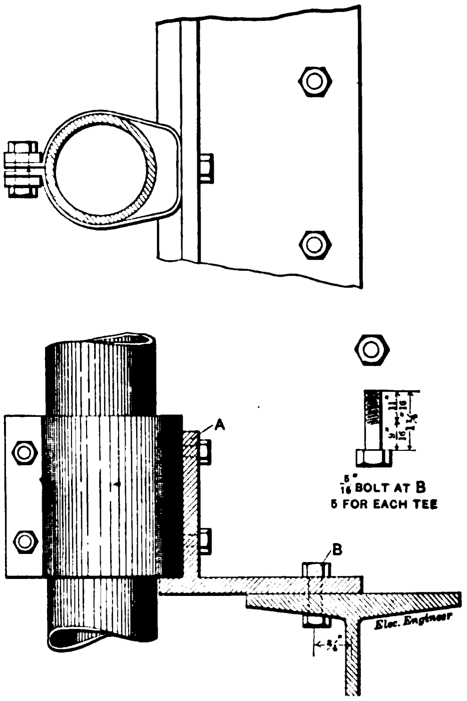
The leads from the generators to the switchboard and from the switchboard to the elevator motors are run in iron-armored conduits under the floors. The positive, negative and equalizing bus bars pass in a horizontal direction across the back of the switchboard; the elevator bus bars are connected through circuit breakers to the rheostats controlled by the pilot motors which govern the operation of the elevator motors proper. Another noticeable feature of the switchboard is that there are no feeder switches, the feeders being connected to the lighting bars through automatic circuit breakers.

THE ELEVATORS.

The three elevators are of the improved Sprague screw type and embody the latest developments in electric elevator machinery. At the bottom of the shaft of the elevator nearest the street door is placed an auxiliary machine operating a drum, the cable from which can be connected whenever desired to the counterweight of the elevator to furnish additional power for the raising of safes or other heavy loads.

DISTRIBUTION SYSTEM.

The system of distribution is as follows: A vertical shaft runs the entire height of the building with openings, protected by folding iron doors, in the main hallway of each floor. The shaft measures 3 feet 6 inches by 12 inches and accommodates both electric lighting and telephone cables, the former occupying the northern end and the latter the southern end. The openings in the shaft are framed with steel beams, the floor beams of the building forming one side of the frame, to which the iron-armored conduits containing the lighting cables and the lead-covered telephone cables are fastened by means of the regular telephone cable clamp. This clamp is a split iron tube, four inches long, which binds on the cable by means of a pair of bolts and nuts; the purchase obtained is so firm that it was found impossible in a recent test to budge a cable so clamped by hauling on a lever three feet long clamped on just above the clamp undergoing the test.



THE "TELEPHONE" CABLE CLAMP.

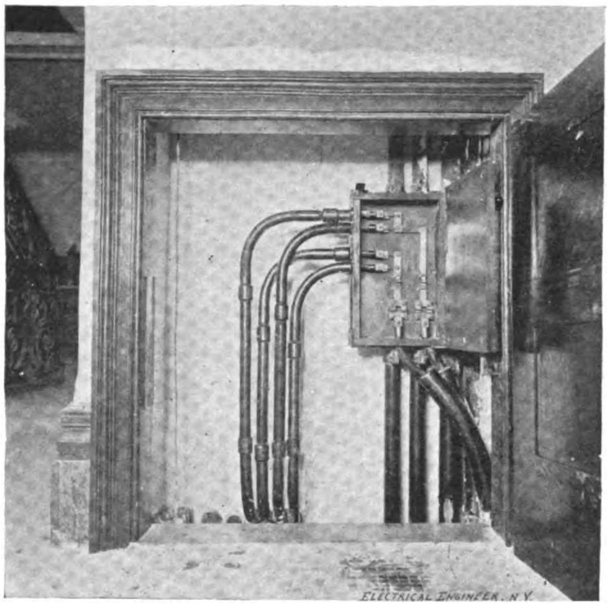
Through the shaft, from the basement to the twelfth floor, extends a pair of mains of 133,000 circular mils cross-section, placed in 1¼-inch iron armored conduit; these mains open at each floor into slate boxes bound with iron, supported on the frame of the shaft, at which connection is made with the submains supplying the various rooms on each floor. From the switchboard run three sets of feeders which are connected to the mains at different floors through slate junction boxes. The first pair of feeders are of 214,000 circular mils cross-section, in 1¼-inch iron armored conduit, and connect to the mains at the second floor; the second pair are of 266,000 circular mils, in 1½-inch conduit and connect at the sixth floor; the third pair are 310,000 circular mils in 1½-inch conduit and connect to the mains at the tenth floor.

Each floor is divided into two sections under the scheme of distribution, and from the slate junction boxes two pairs of sub-mains are run in ¾-inch iron-armored conduit under the flooring to two distributing boxes set in the walls of the corridors, one in the north part of the building and one in the south part. These distributing boxes consist of an inner box of slabs of pink Tennessee marble ⅝ inch thick surrounded by an outer case of kiln-dried hard wood, an air space of 2¾ inches separating the two boxes; the front is closed by a heavy bevelled plate glass door in a bronze frame set flush with the wall. On the back panel of the marble box are mounted the terminals and fuses connecting the sub-mains with the branches extending to the fixtures in the different rooms and hallways. In each distributing box is mounted a knife switch connecting the sub-mains with the terminals of the branch circuits. The appearance of these distributing boxes is extremely pleasing and they give an air of finish and thoroughness to the system of distribution which is convincing of the completeness of those portions of the system which are not so much in evidence.

From the distributing boxes the branch circuits go in ⅝ inch iron-armored conduits to the various fixtures, one circuit going to each room and hallway. The conduits are carried as much as possible in the concrete over the iron floor beams, every precaution being taken to avoid notching the wooden sleepers that carry the flooring. All joints in the conduits are made tight with red lead and painted with insulating paint. The conduit is that of the Interior Conduit and Insulation Company.

LAMPS AND FIXTURES.

The lamps used are 118 volt, taking .5 ampere of current, a total drop of 2 volts being allowed for in the mains. The total number of lamps to be installed at present in the new building is over 1,100; in the old building the total number of lamps is 940. Another departure from general practice has been made in adopting chandelier pull switches, which throw on all the lamps in the fixture at once, in place of the wall switches commonly used, thus effecting a very considerable saving in the amount of wire used in the system. The general arrangement of lighting in the various offices consists of one central combination chandelier and four wall brackets.

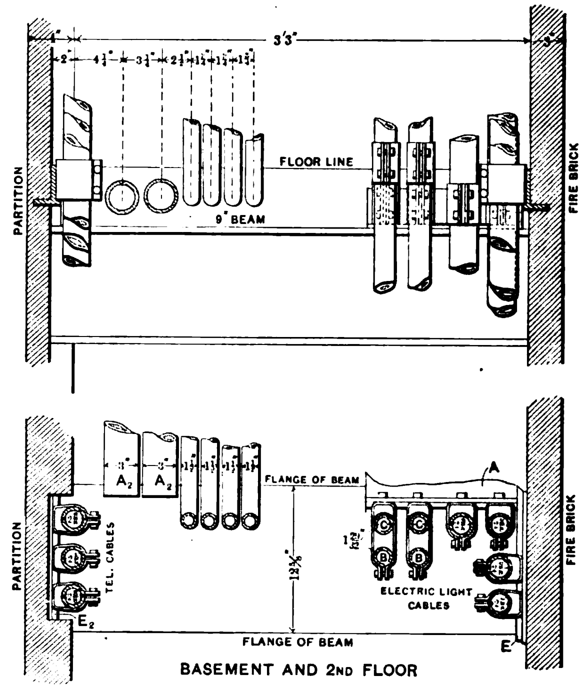


Dey Street Telephone Building.—Cable Shaft, Showing Electric Light Junction Box.

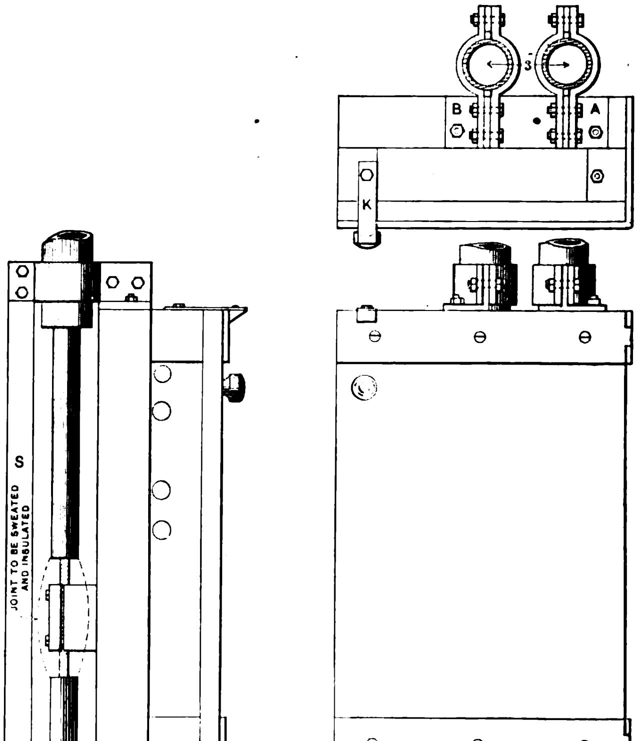
The fixtures are of lacquered brass; each wall bracket is provided with a spare socket at the base of the fixture so that a plug for a portable lamp or for a fan motor may be attached without interfering with the lamp belonging to the fixture. All lamps will be enclosed in opalescent globes and the lamps are all turned upward, a sign of the sensible reaction which has set in lately toward the normal way of placing lights. Since combination fixtures are now so seldom used there is little sense in the turning down of incandescent lamps after the fashion so slavishly followed by fixture makers all these years, and a reversion to the natural and proper position for an ordinary light is quite refreshing.

POWER FOR THE CORTLAND STREET BUILDING.

The lighting and power work of the Cortlandt street building is to be supplied from the new plant by a pair of feeders of 750,000 circular mils cross-section run in 2-inch iron-armored conduit to the present switchboard in the Cortlandt street engine room. At this point the feeders will connect at a special slate junction box with six distribution circuits supplying the old building. These circuits are as follows: East branch, 130 amperes; center branch, 150 amperes; west branch, 175 amperes; long-distance operating room, 30 amperes; sub-cellar, 30 amperes; power circuit, Cortlandt street exchange, 25 amperes.



Arrangement of Electric Light and Telephone Cables in Cable Shaft.



Slate Junction Box in Cable Shaft for Connecting Lighting Mains to Sub-Mains on Each Floor.

When this work is completed the engines and dynamos now supplying the Cortlandt street building will be taken out and the only machinery that will be retained there will be the blowers used for forcing air into the subways for the ventilation of the manholes.

TELEPHONE DISTRIBUTION SYSTEM.

The distribution of telephone wires through the building is effected by means of a miniature subway system running under the various floors. Starting from the underground room in the basement of the Cortlandt street building are two 200-pair cables which run up the cable shaft in the new building, being supported by clamps attached to the steel beams forming the framework of the shaft in a similar manner to the iron-armored conduits containing the electric light mains and feeders. On the various floors two 2-inch wrought iron ducts are extended under the flooring from the cable shaft to two main distributing boxes, one for the north section of the building and one for the south, set in the partition walls of the halls. These distributing boxes contain cross-connecting strips of the usual telephone pattern.

From the main distributing boxes lateral iron ducts of 1¼-inch diameter are carried to sub-distributing boxes placed in the partition walls of the various rooms. From these terminal boxes, each of which serves two rooms, the telephone wires will be drawn through a square duct or way behind the baseboard of the wainscoting; a little door is mortised in the baseboard at each corner of the room, from which points wires may be fished for in either direction. The wires may be brought out from this room duct through the beading at the bottom of the baseboard at the exact points where telephone instruments are needed. In order to pass the doors which afford communication between the different rooms lengths of 1¼-inch iron pipe, with an easy bend, are placed under the door frames, the ends of the pipe giving into the wall duct on either side.

On each floor branch cables will run from the main cables in the shaft through 2-inch ducts to the main distributing boxes, where they will be headed up in flexible heads and connected to the distributing strip terminals, and from these points either smaller cables or separate pairs of wires may be run through the lateral ducts to the room terminal boxes set in the partitions of the rooms. The intention is at first to run separate pairs of wires, except where the number of telephones required justifies the use of a small cable; but the individual pairs may at any time be drawn out and a cable substituted whenever the demand for telephones increases. If at any time fifty telephones were required in one room the necessary wires could be run in a few hours and without any inconvenience.

This system of distribution embodies the maximum of elasticity and flexibility in the arrangement of wires together with extreme durability and great facility for maintenance and prompt location of troubles. The building, as is meet and proper, will undoubtedly have the most substantial and up-to-date system of telephone wire distribution yet devised for an office building. It is to be hoped that architects and engineers who may be called on to lay out the wiring and accommodations for wiring of large buildings will take a hint from the work done at Dey street. In most business offices to-day the telephone takes a more or less important place; in the majority of offices there is at least one telephone and in many cases a number of wires are required in a single suite of rooms. Yet even in the most modern buildings the accommodation provided for connecting the various rooms is ludicrously inadequate, and it is often necessary to run wires or cables up elevator shafts or in through windows. A proper system of ducts, through which cables and wires can be drawn in and out as required, is the only proper and workmanlike method of providing for the numerous telephone circuits required in the modern office building, and the installation in the new telephone building is an excellent model for architects and engineers who desire to be up to date in this important detail of office building equipment.

The internal arrangements of the building call for little remark beyond what has already been described. The ground floor is divided into a large hall, with the entrance at the eastern end of the building, and a spacious department, with two entrances, available to be leased either as one store or two. The main hall will communicate directly with the hall of the Cortlandt street building, making one long hall through from street to street. The main pay station now in the hall at 18 Cortlandt street will be retained there, the arrangements being slightly altered so as to make a clear passage through from building to building. By placing the engine and boiler rooms at the back of the new building two large departments are obtained in the front of the basement and sub-basement available for storage purposes and served by a sidewalk elevator. The principal entrance to the building is No. 15 Dey street.

The second floor is open to tenants, while the rest of the building will be occupied by the various departments of the telephone companies now in 18 Cortlandt street. The rear part of the eighth floor, which is on a level with the operat-

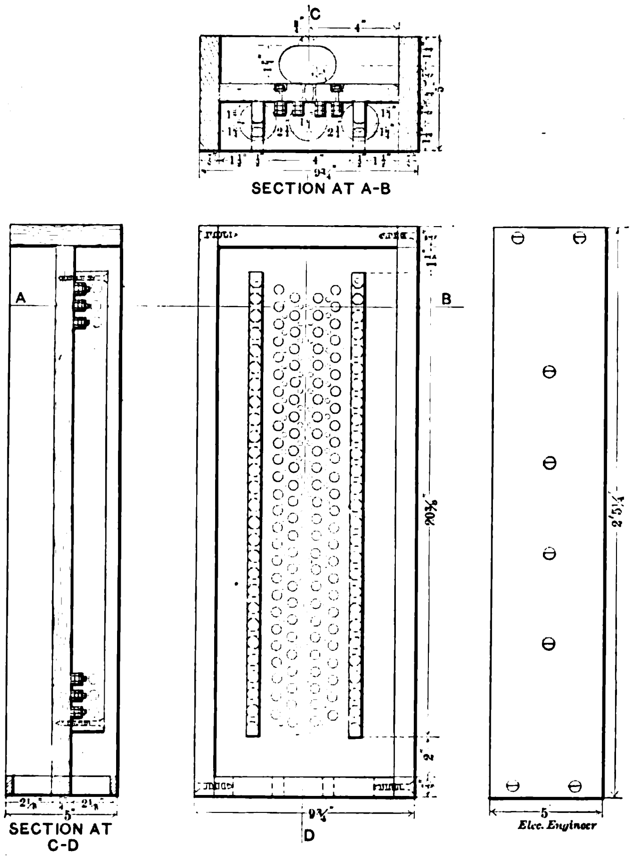
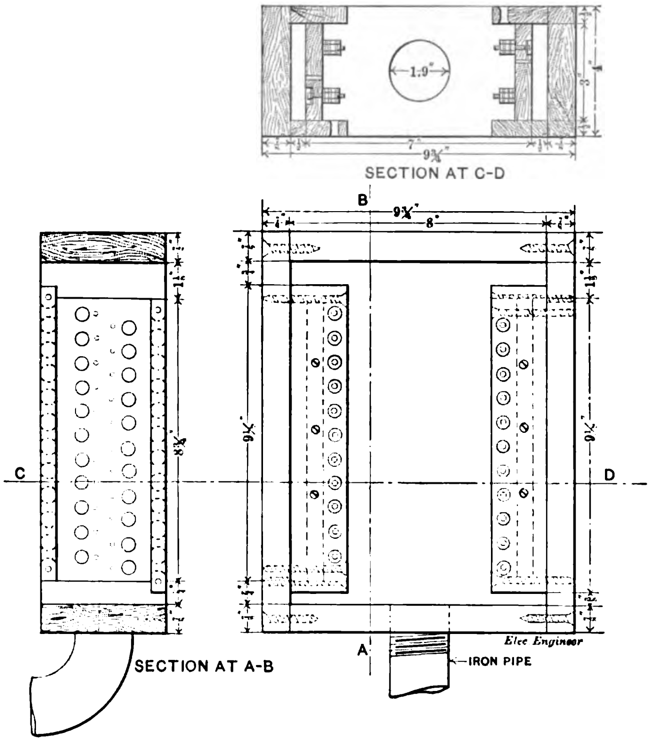
ing room of the Cortlandt street exchange, has been left without partitions as it will probably be ultimately used for exchange purposes. The front part will be occupied by the engineering department of the New York Telephone Company.



Telephone Distribution.—Main Distributing Box.—Two of These on Each Floor.



Telephone Distribution.—Auxiliary Distributing Box Placed in Partition Between Each Pair of Rooms.

The ninth floor will be occupied by the general manager's, contract and filing departments of the New York company, and by the operating room of the common battery telephone system which serves the various offices. On the tenth floor will be the offices of the president and of the secretary of the New York company, and on the eleventh and twelfth those of the executive and general manager's departments of the American Telephone and Telegraph Company.

It is expected that the building will be completed and ready for use before the beginning of April, a pretty quick piece of work, as it was begun in March, 1896.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE—I.

BY JOSEPH APPLETON.

Copyright 1897.

INTRODUCTORY—CONSTRUCTION AND OPERATION OF STORAGE BATTERIES.

THE storage or accumulation of any form of energy or force is an important factor in determining its commercial value. Conditions exist in the daily routine and pursuits of life, which render it absolutely necessary to have a reserve supply of any commodity which is indispensable. With electricity this is especially so. When the secret of storing electrical energy became known its value was greatly enhanced, and to-day electricity is universally acknowledged to be the ideal power on account of the ease with which it can be generated, distributed and stored.

Electricity is stored in a manner which is impossible with any other power. More energy can be contained in a given space and weight than with any other known force. While stored, the energy is dormant, and can be retained for long periods with very little loss. It is capable of being transmitted over great distances with safety, and is always under perfect control.

A better illustration of the above cannot be found than in the utilization of stored electrical energy at the Electrical Exhibition, held in New York City in May, 1896. Electricity generated at Niagara was stored there in batteries, then transmitted by rail to the exhibition and used for sending the congratulatory messages around the world; also for operating various apparatus in the exhibition, such as the model of the Niagara plant in the daytime. Until recent years the storage battery has not played a prominent part in electrical engineering work in the United States. In Germany, England and France its value has been proved beyond a doubt, and it has become an accepted factor in all important electrical problems. Unfortunate litigation was the principal cause of the unsatisfactory results in this country, affecting the industry in two ways; namely, first by preventing capital from becoming interested in the development of the art, and second, by deterring the use of battery installations for fear of protracted and expensive litigation. However, matters have now been smoothed out, and there is no longer any need for electrical engineers to refer to foreign practice as a justification for the use of storage batteries, for here in the United States we can find battery plants, which excel those in Europe, both as regard magnitude and method of installation. Owing to the more general use of electricity in this country and the rapid growth of the same, future prospects bid fair to eclipse the steady and more conservative demand which exists in Europe.

A storage battery, or electric accumulator, consists of one or more cells, each cell being a distinct unit in itself, the number employed depending entirely on the purpose for which they are used.

A cell consists of three principal parts, the plates, the electrolyte and the containing jar or box.

The plates are divided into two kinds, positive and negative, and a set or group of these is commonly known as an element. The element is placed in a containing jar or box, which is then filled with a solution or electrolyte.

Up to the present time only one metal has proved practical for storage battery work; that is, lead. Many others have been tried, and while it is quite possible that future improvements may lead to the use of other metals, notably zinc, for the negative plate, yet the lead storage battery is the only one which can at present be considered a practical piece of apparatus.

The storage of energy in electric accumulators is accomplished by means of chemical action, produced by the passage of an electric current through the element and electrolyte. The lead plates which form the element must be so constructed as to present a large surface upon which the chemical action may take place, as the amount of energy which can be stored up in a cell depends on the capability of the plates to take up the chemical action. This is termed the capacity of a cell. There are several ways of preparing the plates for this end, and they will be considered later.

The positive plates consist of lead, upon which a coating or covering of peroxide of lead has been formed, while the negative plate is pure lead, the surface of which is of porous or spongy formation. The peroxide of lead and spongy lead, respectively, are the portions of the plates which are subjected to the chemical action, and are, consequently, called the active material. The electrolyte used with all lead storage batteries is sulphuric acid diluted with water, the specific gravity ranging between 1.15 and 1.30, according to the type of cell.

The positive and negative plates of each cell are arranged alternately in a group, all the plates of like denomination being connected together in multiple. Insulating pieces, or separators, are provided to keep the plates apart, so that when they are connected respectively to the positive and negative poles of a source of electricity the current can only pass from one to the other by flowing through the electrolyte.

The chemical condition of the plates and electrolyte differs when charged and discharged. When the cell is fully charged the positive plates have a coating of peroxide of lead, the negatives being porous or spongy lead as previously described, and the electrolyte is of its full strength or specific gravity. During discharge, that is, when the positive and negative poles of a cell are connected through an external circuit, an e. m. f. is set up in the cell, a current flowing into the circuit from the positive plate.

The chemical action which takes place during discharge is as follows: The sulphur radical in the electrolyte enters into combination with the active material on both plates forming sulphate of lead, the specific gravity of the electrolyte being correspondingly reduced. When all the active material has been acted upon in this manner, the cell is discharged, for an equilibrium has been created between the two plates and the e. m. f. has fallen to zero. In practice, however, the discharge is not carried to this point, but is stopped before all the active material has been acted upon.

The e. m. f. of a cell during discharge commences at 2 volts or a little over, and drops to 1.8 volts when the cell is discharged down to a practical limit. The discharge might be carried further than this, but only under certain conditions would this be advisable, as will be shown later.

The current which can be obtained from a cell, and the time for which it can be maintained, depends on the number and sizes of the plates, together with their construction.

When a cell is being discharged the chemical action is reversed. The current enters the cell at the positive plate, passing through the electrolyte to the negative. The passage of the current through the electrolyte decomposes it, oxygen and hydrogen gas being given off. The oxygen is given off at the positive plate and converts the sulphate of lead into peroxide of lead again, the sulphur going back into the electrolyte; the hydrogen which is given off at the negative plate enters into combination with the sulphate of lead, reducing it to pure lead, the sulphur returning to the electrolyte and increasing its specific gravity. This action restores both plates and electrolyte to the original condition of full charge. If the charging current is continued after the cell is fully charged; that is, when all the active material has been reconverted to peroxide of lead and spongy lead respectively, the oxygen and hydrogen gas will be given off in bubbles.

Naturally the chemical action can only take place at a certain rate, depending on the amount of active material and the construction of the plates. If it is attempted to give to, or take from, a cell too much current the efficiency and durability are affected. The given output of current per unit of weight and area of plate or capacity will be considered in a subsequent chapter.

Generally speaking, there are two distinct methods of preparing the active material of storage battery plates. One of these consists in applying mechanically some material to the surface or exterior of a lead conducting plate or grid, which is either active itself or can be converted into active material by a process of electrical or chemical formation. The second method consists in treating or forming electrically or chemically the surface of a lead plate, which has been designed to present a large area to the electrolyte, whereby the surface is converted into active material.

The first method is commonly known as the "pasted" type of cell, although the active material is not always applied in the form of paste. The second method is known as the "Planté" type, so called because Gustave Planté was the first to utilize practically the electrical method of forming the plates without the use of applied material.

It will be seen from the above description that the storage of electrical energy is entirely different from the storage of any other form of energy. A quantity of electricity cannot be stored or accumulated in a vessel or reservoir, because it does not exist in a tangible form. We are able, however, to make the electric current perform work in the shape of chemical action and afterward, by setting up certain reactions, can reproduce the current stored. As long as the materials used are free from impurities and the chemical action is continued until completed, there is practically no limit to the time which may elapse between the storage of electricity with its contingent chemical action and the reaction which, practically speaking, sets free again the electric current.

Having considered the principles upon which the storage of electrical energy depends, and noted the various elements which are necessary to make up the complete cell or storage battery, we will now examine the various types of cell, which are the outcome of all the time and money expended on the attempts to produce the ideal storage battery.

AMHERST EXPERIMENTS ON THE ELECTRO GERMINATION OF PLANTS.

THE Hatch Experiment Station of the Massachusetts Agricultural College has just issued a bulletin (No. 43) on "Electro Germination," which describes an extended series of experiments carried out by Mr. Asa S. Kinney. This work is of such general interest and value that we give below an extended abstract of the bulletin, from which the accompanying illustrations are also taken.

The experiments have followed in many instances those of Specnew. The objects of these experiments have been three-fold. First, to determine whether the seed germ responded in any way when subjected to electrical influence. Second, should there be any visible action, to determine whether it was injurious or beneficial. Third, to determine the effect of different strengths of current. These experiments have been carried on from a scientific standpoint rather than from any practical application to which they may be put, although with proper apparatus the use of electricity may prove of considerable service in the germination of some small seeds which under ordinary conditions start very slowly.

Apparatus and Methods.—The kinds of apparatus and the methods described are those which gave the best results.

The batteries used in the experiments were of two kinds, namely, four Leclanché cells arranged in series giving an electro-motive force of from four to five volts and two No. 1 Samson cells giving an electro-motive force of two and eighty-eight hundreth volts.

In order that a large variation in electro-motive force could be obtained, an induction coil was employed. The one in use was a Du Bois-Reymond inductorium, manufactured by the Cambridge Scientific Instrument Company, England. This coil is a form of the Ruhmkorff apparatus, but has several special modifications which make it especially adapted to this form of experiment. In Fig. 1 there is shown at I a side view of the coil as it is set up for use. The primary coil, C, consisting of a core of soft iron rods, is fixed and wound with about one hundred and thirty turns of moderately thick insulated copper wire. The secondary coil, B, having six thousand turns of fine copper wire, is quite separate from the primary coil and slides in a groove in the wooden standard. In this way the secondary coil may be brought over the primary coil or removed quite a distance from it.

In some of the experiments hourly treatment was desired. This was accomplished by passing the wires from the battery to an electric clock and thence to the induction machine. Each hour, the clock formed a connection completing the circuit and a current was passed through for a period of about thirty seconds.

Methods of Applying the Stimulation.—In some experiments the apparatus represented in Fig. 2 was used. This consisted of two glass cylinders, a larger one about two inches in diameter for large seeds and a smaller about three-fourths of an inch in diameter for those of less size. Within these cylinders, thoroughly moistened seeds were placed and the openings closed with copper discs having wires attached. By means of these wires the discs were connected with the poles of the induction coil and a current passed through, the moist seeds making a good conductor. After the seeds had been

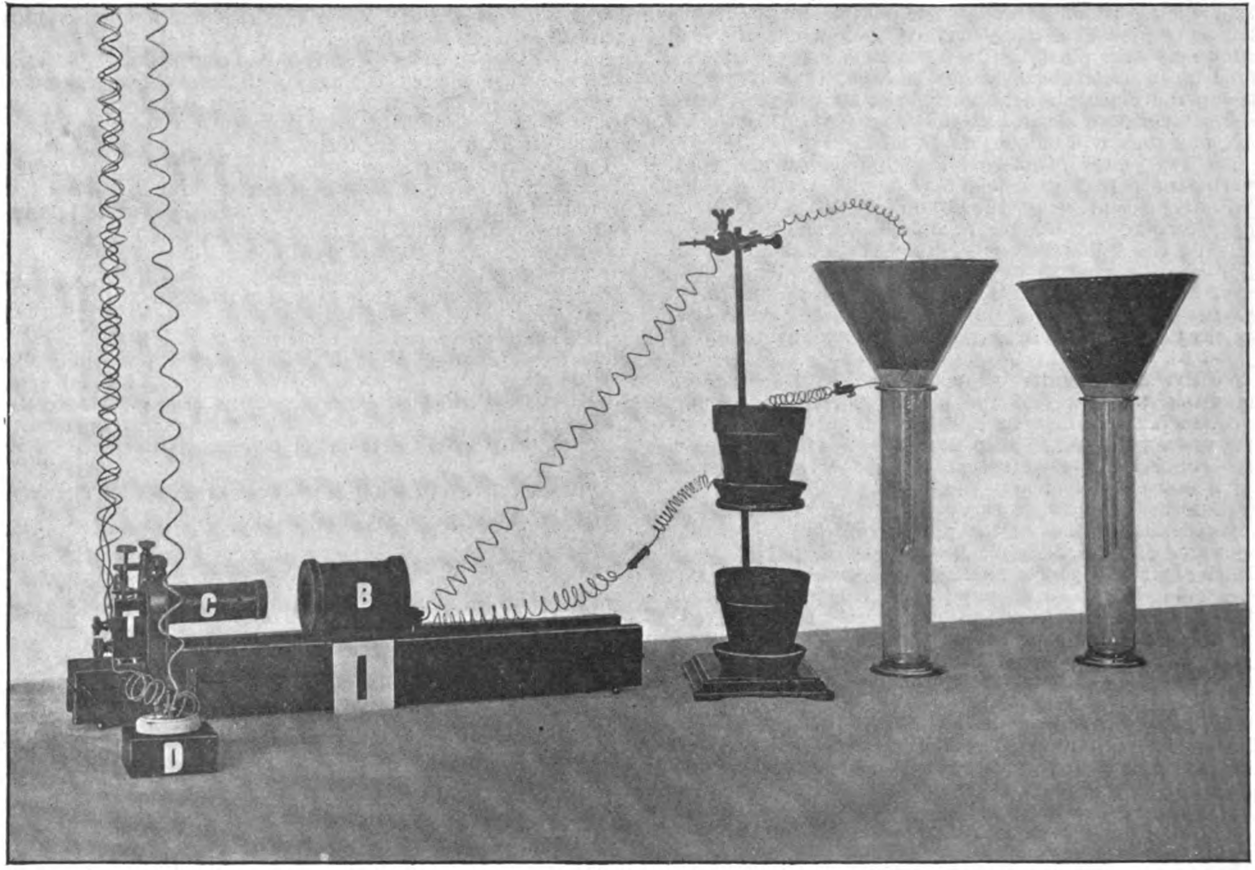


FIG. I.—INDUCTION COIL AS ARRANGED FOR ELECTRO GERMINATION WORK.

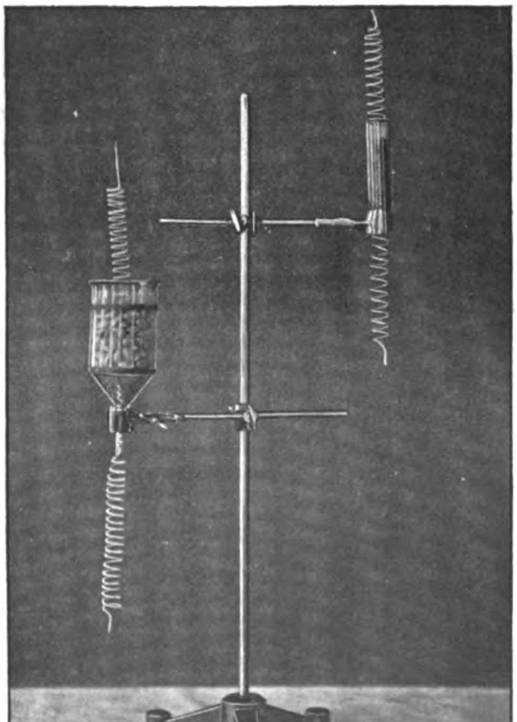

FIG. 2.—ELECTRO GERMINATING APPARATUS.

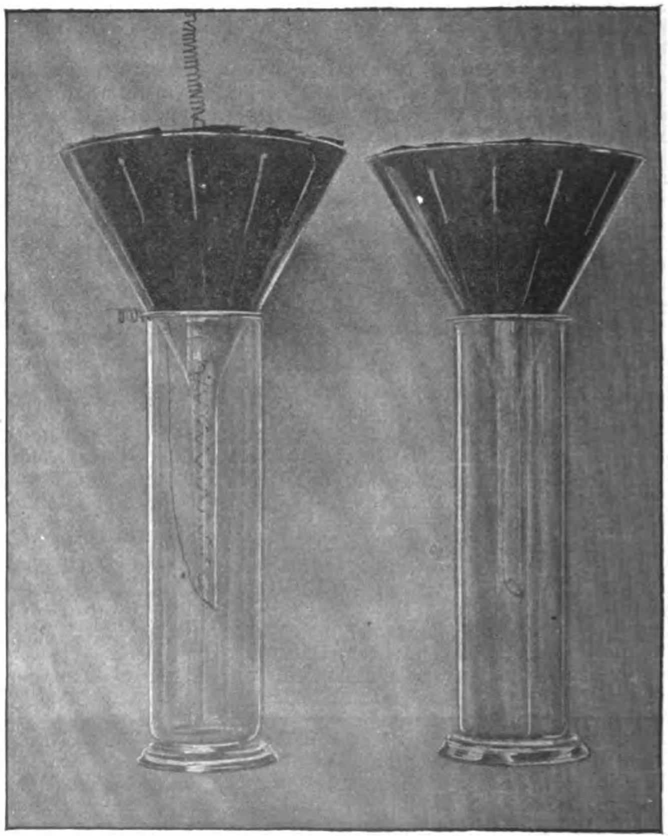

FIG. 3.—ELECTRO GERMINATING APPARATUS.

stimulated by passing the current through them they were placed in germinating pans as shown in Fig. 5.

Another method of applying the stimulation is shown in Fig. 3. This consists of two seven-inch glass funnels. Within each of these funnels are two copper discs, a small one at the bottom and a larger one at the top. In the upper disc of each funnel are twelve holes, at equal intervals around the edge, to allow the hypocotyls to grow through. Between the discs of each funnel is placed a layer of moist sand in which the seeds are planted. To the discs of one funnel are attached wires, by means of which they are connected with the poles of the induction coil. In this way a current may be passed through the moistened sand which acts as a good conductor.

The object of taking a funnel, rather than a cylinder, is that the action of gravity constantly draws the roots against the glass, allowing measurements to be taken from the outsides, whereas were the sides vertical, nutation and such forces as hydrotropism might cause the root to grow inward and away from the glass.

In experiments with this apparatus the seeds were first germinated in sawdust, and when the radicles had reached a length of about two centimeters they were removed to the funnels where the subsequent growths of the normal and stimulated plants were compared.

In Fig. 4 is shown an apparatus very similar to that in Fig. 3, with the exception that in this case four-inch clay pots were substituted for the funnels. This apparatus is not adapted for observation of root growth, but simply that of the hypocotyls. In the upper discs are seven holes through which the young seedlings grow, as shown in the diagram in Fig. 4, which represents a cross section of the pot where the plants were treated with electricity.

Germinating Apparatus.—In the selection of germinating pans for this work two chief points have been taken into consideration. First, that the normal or untreated seeds should have exactly the same environments as those treated, aside from the conditions brought about by the application of electricity. Second, that the conditions for germination should be as favorable as possible, that is, that there should be the proper amount of heat, air and moisture to give the best possible conditions.

The form of apparatus which was used in these experiments, and which seems to fulfil the requirements very well, is shown in Fig. 5. This consists of two plates, an outer of porcelain about nine inches in diameter, and an inner of clay seven inches in diameter. Within the inner plate filter-paper is placed upon which the seeds are sown. In the outer plate a constant supply of water is kept which gradually passes through the plate of porous clay, keeping the filter-paper within constantly moist. The seeds are sown upon the filter-paper in the manner shown in the left-hand pan in Fig. 5. The paper is divided into eight equal parts; seven of these are used for the treated seeds, while the eight or 0 is for the normal or untreated seeds.

A second piece of moist filter-paper is placed over the seeds, resting upon them and touching at various points the paper beneath. In this manner the covering is kept moist by absorption. A plate prepared for germination is shown at the right in Fig. 5. In order to insure perfect darkness a piece of black cardboard was placed over the pan in such a manner as to shut out the light, but not prevent a free circulation of air.

In this form of pan the young plants can be grown without difficulty until the hypocotyls are two or three centimeters long. The moist filter-paper, which constitutes the covering of the seeds, offering but little obstruction to growth.

Effects of Electricity in Germination and Growth of Radicles, (Roots).—Experiments were made with White Mustard (Brassica alba, Boiss) Red Clover (Trifolium pratense, L) Rape (Brassica napus, L.) and Barley (Hordeum vulgare, L.) The seeds were treated with an interrupted induced current from a Du Bois-Reymond induction coil for a period of two minutes, the coil being connected with a four Leclanché cell battery. Two-hundred seeds of each variety were taken. These were soaked in water for a period of twenty-four hours, after which each lot of two-hundred seeds was divided into eight lots of twenty-five seeds each. Seven of these lots were treated with the electric current in the apparatus shown in Fig. 2, as previously described. The eighth was left untreated and served as normal plants for comparison. After treatment, these seeds were sown in germinating pans as shown in Fig. 5, which, after having been prepared for germination, were placed where the temperature was kept from 18° C. (64.4° F.) to 20° C. (68° F.).

An average was made of the 1,600 seeds germinating in 24, 48 and 72 hours respectively. The following table shows the result obtained by such an average:

		Treated.	Untreated.	Gain per ct. by treatment
Average number.. seeds germinated in each lot in....	24 hours	9.93	7.50	32.40
	48 hours	18.00	14.87	21.05
	72 hours	19.14	18.00	6.33

From these results it will be noticed that by applying electricity germination was considerably hastened, and that those lots of seeds which received treatment, gave a higher percentage of germination at the close of the experiments. An examination of the tables seems to prove that the electric current awakened life in some seeds which, without treatment, would have remained dormant.

Some of the results seem to show that there is an optimum strength[1] of current for germination as well as for growth of radicles.[1]

Effects of Electricity on Germination and Growth of Radicles (Roots) and Hypocotyls[2] (Stems).—Experiments were made with White Mustard (Brassica alba, Boiss) Rape (Brassica napus, L.) and Red Clover (Trifolium pratense, L.).

The experiments are similar to those previous, with the exception that measurements were also taken of the hypocotyls, in which case it was more convenient on account of the greater maturity of the hypocotyls, to make the measurements at the end of 96 hours instead of at 72 hours as in the previous tables.

An average of the number of seeds germinated in the various lots in tables IX.—XI. gives the following:

Average number seeds germinated in each lot in	Treated.	Untreated.	Gain per cent by treatment.
24 hours	13.33	11.33	17.65
48 hours	17.19	15.33	11.47
72 hours	18.43	18.00	2.38
96 hours	18.43	18.00	2.38

These results do not show so high a gain by use of electricity as in the first series, but prove that at the end of 72 hours all the seeds that retained vitality would germinate.

A Comparison of Different Kinds of Current.—In these experiments the seeds were treated with three forms of current.

The average growth of radicles and hypocotyls and gain per cent. were as follows:

Kind of current.	Average growth (in centimeters) of radicles in 72 hours.	Gain per ct. by treatment.	Average growth in (centimeters) of radicles in 96 hours.	Gain per ct. by treatment.	Average growth (in centimeters) of radicles in 96 hours.	Gain per ct. by treatment.
Normal	1.95	0	4.00	0	2.96	0
Interrupted induced..	2.96	51.79	4.67	16.75	3.22	8.78
Inter'pt'd induced 10 interruptions	2.93	50.25	4.52	13.00	3.13	5.74
Direct	2.47	26.66	4.17	4.25	2.99	1.01

It will be noticed from these results that the interrupted induced current, where ten interruptions were used, gave the highest percentage of germination, but the experiments have not been repeated enough times to definitely ascertain whether this will always follow. It will also be noticed that the interrupted induced current, where the Wagner hammer was used, gave a much longer growth of radicles and hypocotyls, and, in fact, this form of current has given the best results in all the experiments which were carried out.

Where the direct curent was used, the gain was not as high as with the other forms. These experiments, and others which have been made since, seem to prove that the optimum strength of direct current is of somewhat lower voltage than with the induced current, and that the cause of the low gain per cent. in the tables is due to the fact that the optimum strength of direct current was not used.

Effects of Hourly Treatment on Horse Bean (Vicia faba, L.).—For this work the apparatus shown in Fig. 3 was selected, as it gave a good chance for examination of the radicles from time to time, and in it the plants could easily be subjected to the electric current.

The glass funnels were filled with moist sand to within about an inch of the top, as stated in the description of Fig. 3. Twelve small holes were made in the sand along the inner surface of each funnel and in each of these holes a bean radicle was placed, the bean itself resting upon the surface of the sand. This having been done, the funnel was filled with sand, covering the beans to a depth of about one-half inch. The copper discs were placed upon the sand and the plants treated. Fig. 3 shows an apparatus set up in this way, the seeds in which receiving hourly stimulation lasting about thirty seconds for a period of forty-eight hours. The discs of one funnel were attached to the poles of the induction machine, the secondary coil being removed five centimetres, and a current was passed through hourly from a four Leclanché cell battery during the experiment.

---

[1] The optimum current or stimulation is that which gives the best result.

[2] The term Hypocotyl is used by botanists to indicate that portion of the stem below the cotyledons or seed leaves.

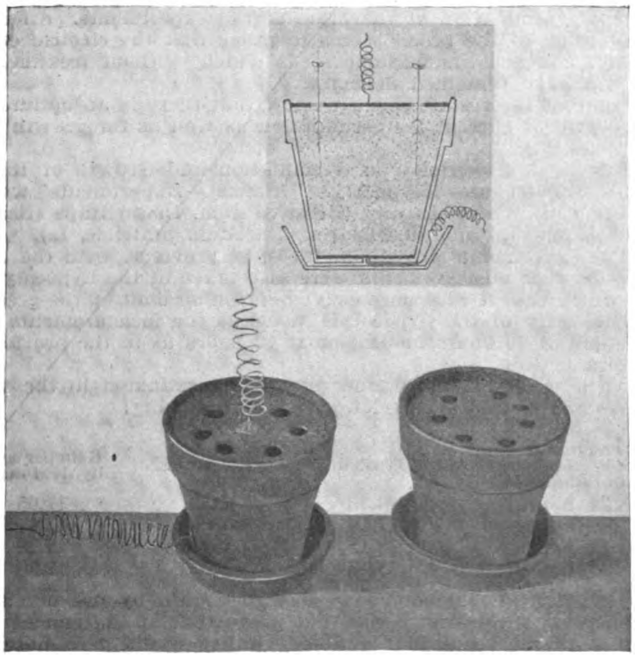

FIG. 4.—ELECTRO GERMINATING APPARATUS.

The effect of hourly stimulation upon the growth of radicles of Horse bean (Vicia faba) was as follows:

Time.	Treated.	Untreated.	
	Average increase in length of radicles in centimeters.	Average increase in length of radicles in centimeters.	Gain per cent by use of the electric current.
12 hours	1.87	1.57	19.11
24 hours	1.58	1.09	44.95
36 hours	2.53	1.78	42.13
48 hours	2.65	1.90	39.47

In this table it will be noticed that in the first twelve hours the gain by treatment is not so great as at subsequent periods, a fact which has been seen in all of the other experiments in this line, but the cause of which has not been fully ascertained.

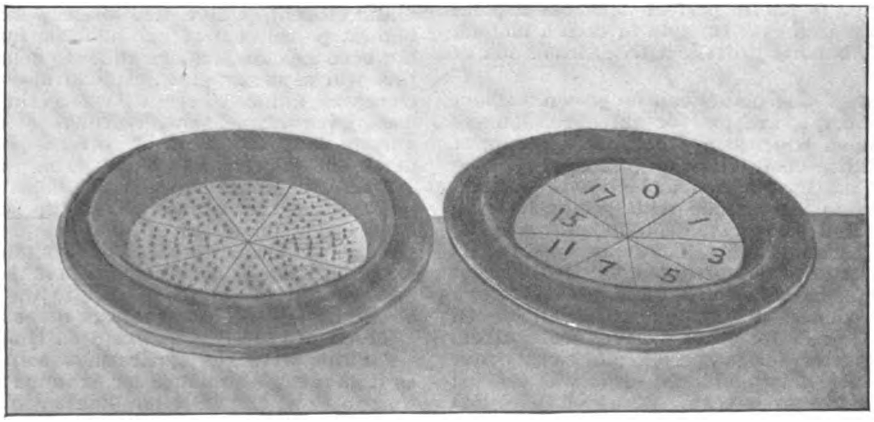

FIG. 5.—GERMINATING PANS.

This experiment, as do others which have been made, but which are not recorded in this work, shows a decided increase by treatment, proving conclusively that the beneficial effect of electricity upon growing plants is quite constant.

SUMMARY.

1. Electricity exerts an appreciable influence upon the germination of seeds.

2. The application of certain strengths of current to seeds for short periods of time accelerates the processes of germination.

(a) As a result of experiment it has been found that at the end of twenty-four hours over 30 per cent. more seeds were germinated in the treated lots than in the normal. At the end of forty-eight hours about 20 per cent. and in seventy-two hours 6 per cent.

3. Those lots of seeds, receiving electrical stimulation gave a higher percentage of germination than the normal.

4. The range in the strength of current which accelerates germination is exceedingly limited.

5. The effect of electricity upon the germination of seeds shows that there is a maximum, optimum and minimum current.

6. The minimum strength of current which just perceptibly accelerates germination when an interrupted induced current is used, is quite close to number 17 in the tables and probably represents considerably less than one volt.

7. The optimum strength of current which shows the maximum growth of radicles and hypocotyls is equal to about three volts where an interrupted induced current is used.

8. The maximum current which the seed germ can withstand without being destroyed has not been ascertained in these experiments, but probably represents a comparatively high voltage.

9. The optimum strength of current is practically constant for such small seeds as mustard, red clover, etc.

10. The optimum current for radicles and hypocotyls is the same.

11. Seeds subjected to but one application of electricity show the effect only for a few hours.

(a) In those lots of seeds which received an optimum strength of current, an increase of over 30 per cent. in the length of radicles was found at the end of seventy-two hours, while at the end of ninety-six hours this increase was less than 15 per cent., showing that the beneficial effect was lost as the plants matured.

(b) The gain in the hypocotyls by use of an optimum current was about 13 per cent., or a little less than that of the radicles in the same lots of seeds.

12. Electricity when applied hourly to germinating seeds or growing plants, does not lost its effect, but acts as a constant stimulation to their growth and development.

BETTING ON RAPID STREET RAILWAY CONSTRUCTION.

Frank Miller and Clinton Cribbs, of Benton, Harbor, Mich., got into a dispute as to whether the Benton Harbor & Eastern Electric Railway will be built to Sister Lakes within the next 90 days, as the company says it will, and, finally, they each wagered a house and lot worth about $1,000. Deeds for both pieces of property have been placed in the hands of a stakeholder, to be delivered to the winner at the expiration of the time.

THE PACHUCA POWER PLANT.

THE City of Pachuca, State of Hidalgo, Mexico, is famous for the richness of the silver mines which, for over two hundred years have been continuously adding to the wealth of Spain and Mexico. This picturesque city is located on the edge of the valley of Mexico and behind it rise the Sierra Madre Mountains, on whose sides are located the building of the mines which are the largest producers of silver in the world, the annual output amounting to about $12,000,000, Mexico money.

With such extensive workings much power is necessarily required and as the wood fuel of the region was long ago exhausted, coal is imported, costing $20 a ton in Pachuca and from there is carried over the mountain roads and burro trails to the mines. In addition to the mines themselves, the haciendas de beneficia or Ore Reduction Works, in Pachuca and the neighborhood are large users of power.

On the other side of the mountain range, about twenty miles east of Pachuca is the Rio Regla, a mountain stream which for generations has furnished power to the mining haciendas of San Miguel and Regla by means of ancient overshot wheels built in the early days of the old Spanish viceroys. At Regla it falls over the basaltic cliffs into the Cañon of Regla and rapidly descends for some five miles until the bottom of the barranca finally reaches a depth of 2,000 feet below the flat surrounding country about it.

That distinguished Mexican engineer, Señor Rafael M. de Arozarena, conceived the idea of developing this power and formed the Compania de Transmission de Potencia, del Estado de Hidalgo, at the head of which was Senor Jose de Landeroy, Cose, of the Real del Monte mines of Pachuca. The preciptous walls of the upper cañon and the loose crumbling detritus which composed the sides of the lower barranca presented difficulties which it required more than two years' work to overcome. The plant, however, was completed at the beginning of the present year, and is now in regular operation.

Just below the waterfall and hacienda of Regla the hydraulic work begins by the construction of a dam across the cañon to divert the water into the canal. The river, although usually but a small arroyo of about fifty cubic feet per second, during the rainy season becomes a torrent of enormous proportions so that it was found necessary to construct a heavy masonry dam, with a massive feed gate bulkhead at the side to protect the canal.

At first the canal runs in a cut in the face of the cliff, the overhanging rock being supported by masonry piers. From this point on, it passes over an aqueduct through no less than seven tunnels, with stretches between of open ditches cut either in the solid rock or securing a difficult foothold in the sloping débris under the cliffs. The length of the canal is nearly two miles, with a grade of 8-10 of 1 per cent. to prevent filling with sand, and is lined throughout with masonry faced with cement. It ends in a mesa in the barranca in a tank from which the pipe runs to the power house 800 feet below.

The pipe line consists of 1,700 feet of thirty-inch pipe of steel, one-eighth-inch in thickness at the top and three-quarter-inch at the bottom. The lower half of the pipe line is at an angle of 45 degs., and here the pipe is completely embedded in masonry stepped into the side of the barranca.

The power house is a handsome masonry building in the Spanish style of architecture, with a structure at one side for the receiver valves and water wheels. The pipe is connected by a main valve to the receiver, which is forty inches in diameter, seventy-five feet long, and three-quarter-inch thick. It weighs 50,000 pounds, and was tested for 700 pounds pressure. Attached to the bottom of the receivers are the valves and deflecting nozzles for five forty-inch diameter, 400 horse-power Pelton water wheels running at 600 revolutions per minute, and two twenty-four-inch diameter, forty horse-power wheels at 1,750 revolutions. Under the wheels is the tail race, covered on the sides with timbers and on the bottom with plates of iron in order to stand the impact of water at such a high velocity—even the iron being cut away by the jet from the nozzle and having to be replaced at frequent intervals. The shafts of the water wheels pass into the power house through iron water-tight ports in the wall, and are connected by flange couplings to the generator shafts.

The five generators are G. E. three-phase alternators of 300 kilowatt capacity, each built with twelve poles, for a speed of 600 revolutions, a potential of 700 volts and a periodicity of 60 cycles per second. The exciting current is derived from two 25-kilowatt Edison bipolar 125-volt machines, each of sufficient capacity to excite the fields of all the generators. On the wall by the side of the generators are the Pelton differential governors for controlling the wheel speeds by deflecting the nozzles and the hand wheels for working the valves.

Opposite the generators are the step-up transformers and switchboards. The transformers are of G. E. manufacture, seven in number, of 200 kilowatt capacity each, and raise the potential from 700 to 10,000 volts. Two 50-inch blowers driven by small direct-connected motors force air for cooling through the transformers. The switchboard consists of fifteen panels of blue Vermont marble and on them are mounted the instruments and switches for the generators, exciters, transformers and lines.

The transmission line passes in a direct line over the mountains of Pachuca, with lateral branches to the Difficultad and San Rafael mines. The distance from the power house to Difficultad is twelve miles, to San Rafael, nineteen miles, and to Pachuca seventeen miles. The loss of power in transmission is 10 per cent. at full load. The transmission line is No. 3 B & S wire on G. E. porcelain insulators, carried on iron poles with iron cross arms. It is thoroughly protected from lightning by G. E. ball lightning arresters.

At Real Del Monte is the substation for the Difficultad mine in which are three 120-kilowatt step-down transformers changing the potential to 1,000 volts, and marble switchboards. Underground in the mine are four Knowles horizontal plunger pumps driven by induction motors. The pumps are 7¼-inch x 12-inch triplex double-acting, of a capacity of 600 gallons per minute against a head of 300 feet and are driven by 1,000 volt 75-horse-power motors running at 600 revolutions per minute. Both motor and pump are mounted on the same cast iron base, forming a rigid self-contained unit.

The San Rafael substation contains three 90-kilowatt air blast transformers with marble switchboard and small blower ventilating set. Current is carried underground at 1,000 volts by lead-covered cables to two 50 horse-power three-phase induction motors geared to horizontal duplex double-acting Dow pumps, arranged to be operated either by electricity or steam. These station pumps have each a capacity of 300 gallons a minute against 600 feet head, and are partially fed by two 20 horse-power General Electric sinking pumps of a capacity of 125 gallons against 300 feet head. The sinking pump is of particularly compact design so as to pass down the narrow shaft. The motor is completely enclosed, the ends of the armature bearings even being fitted with stuffing boxes, so that the constant fall of water from above, or even the complete submersion of the pump can do no damage to the motor. The potential used for the sinking pumps and the electric lighting of the mine is 110 volts, obtained from oil transformers. The recent flooding of the lower levels of this mine has called for largely increased pumping machinery, which is now under construction and will be driven by electric power.

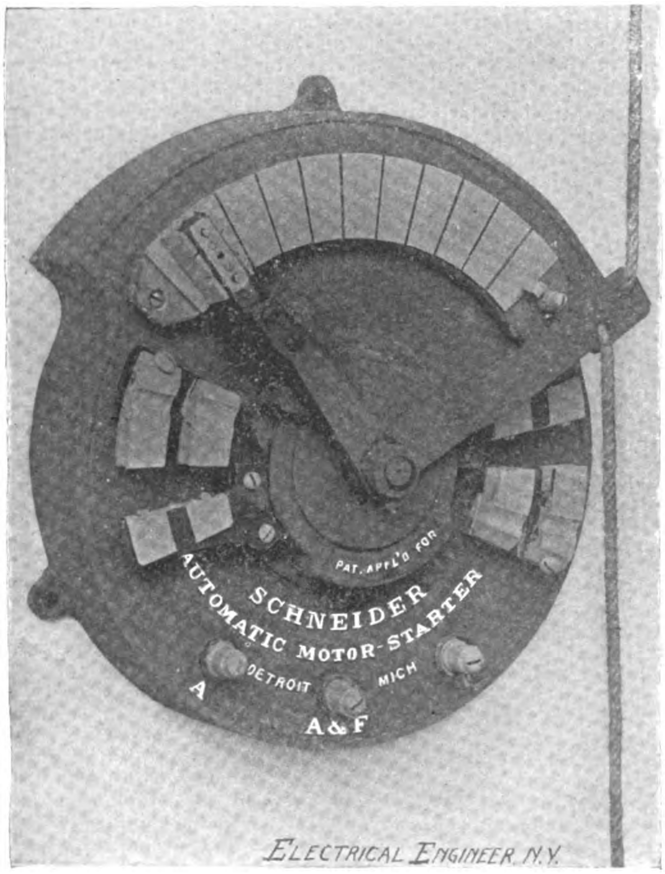
The silver is obtained from the low grade ores of Pachuca almost entirely by the patio system. In this system the crushed rock is first pulverized by stone arrastras or Chilian mills. The resulting slime after passing through settling tanks is conveyed to the patio court of the hacienda, where mercury, sulphate of copper and salt are added and the metal amalgated by the slow process of driving horses around in the "torta" of ore for weeks continuously. In place of the patio process the barrel amalgamator is also used to some extent.

In Pachuca the substation is a large building of Moorish design. In it are the offices and store rooms of the company and the substation proper, containing three 40-kilowatt and three 90-kilowatt transformers with space for a large increase in capacity, together with switchboards, blowers, etc. The Guadalupe Hacienda uses three 50 horse-power G. E. 1,000-volt induction motors, running at 720 revolutions, which drive fourteen Chilian mills and a large rock breaker. The buildings and grounds are lighted by a 10 horse-power motor generator set, consisting of an induction motor and continuous current generator, continuous current being employed on account of the arc lighting. Some small pumps are also employed.

The Union Hacienda uses a 150 horse-power 1,000-volt induction motor at a speed of 600 revolutions to drive thirteen barrel amalgamators, a 100 horse-power and 50 horse-power motor for twelve Chilian mills and their rock breakers. The Bartolome de Medina Hacienda uses two 50 horse-power 1,000-volt induction motors, which are used also for Chilian mills and amalgamators.

SCHNEIDER AUTOMATIC MOTOR STARTER.

THE engraving herewith illustrates a new automatic motor starter recently brought out by Mr. George J. Schneider, of Detroit, and now being manufactured and sold through Messrs. Thomas Muir & Son, of Detroit, Mich. There are a number already in successful service in Michigan and Ohio. The switch controls elevator plants under all direct current voltages, including 500 volts, in the most perfect and reliable manner. This high voltage being taken from street railway current, is necessarily of a very varying character and difficult to control automatically; but the Schneider starter overcomes all difficulties, and secures a steady and reliable service under all conditions.



THE SCHNEIDER AUTOMATIC MOTOR STARTER.

The special features of this starter are the fewness and simplicity of the working parts, no solenoid and dash pot, and extra independent knife switch being entirely dispensed with.

In case of failure of the current, the main switch on the box is thrown automatically open, insuring perfect safety against a short circuit, either of the box or motor. As will be seen, the apparatus is controlled by rope from any floor, and, besides the elements of safety, it effects great economy in expense of operation.

Owing to the simplicity and perfection of the mechanism, the switch can be thrown out and in quickly in succession without delay or damage.

ELECTRIC POWER FOR CRIPPLE CREEK.

The Colorado Electric Power Company, which has been recently organized, will establish an electric generating plant near Cañon City, and will furnish power to mines and mills in the Cripple Creek district. The officers of the company are: O. B. Shallenberger, J. H. Haynes, J. R. McKinney, H. G. Lunt, R. F. Howland, W. P. Bonbright and D. V. Donaldson. Nearly all the stock will be held by Colorado Springs parties.

The company has secured water rights and a large coal mine near Cañon City, where the plant is to be erected. Twenty miles of wire will connect the plant with Cripple Creek.

LETTERS TO THE EDITOR

EXPENSES AND PROFIT OF CENTRAL STATION OPERATION.

HAVING looked over your issue of February 17, giving data on municipal plants, I fail to find anything encouraging to the advocates of municipal ownership in them, when subjected to a fair analysis. As far as the taxpayers are concerned, it appears to be a case of "heads I win, tails you lose." If earnings fall short of expenses the balance is taken from the general fund. If a surplus is shown, it is taken for granted that rates are too high and they are lowered, leaving in many cases the little items of interest, depreciation and bonds issued, to posterity—a legacy to remind them of how something could be produced from nothing in times past, but not now. I also note your editorial remarks on the same subject, with regard to educating the public to know that in most cases it does not pay, etc. There is another point upon which the public also needs educating, and I have never yet seen it raised by any writer on the subject, and that is, that in allowing the electric light people to use the streets of a city or town for the distribution of their product, there is nothing more given to them than is freely accorded to everybody else, namely, the free use of the highways for the purpose of serving their customers. All other manufacturing and jobbing interests are allowed this use without question, and in order that they may do so without interruption the streets are paved and kept in repair by the abutting owners and the municipality itself. That the distribution of electricity requires permanent fixtures is that much the worse for the business and those engaged therein, as it requires a large investment in material which once placed is of not much use elsewhere. Another point that I cannot reconcile is how a person or company can be expected to erect a plant at great cost, keep it in operation through thick and thin, and the only return to be the legal rate of interest on money invested for a term of years. If more than this is earned above expenses, repairs and taxes, a howl is raised that they are robbing the people and the threat of a municipal plant is held over them. These rigid requirements would be all right if the business was permitted to be established on a permanent basis, but if all parties understand that it is to be temporary or limited only, then in all fairness the return must be such as will repay the original investment with interest for the time used. There would be serious doubts of a man's sanity who would erect a building of like cost upon ground of which he only held the lease for a limited time and be required to rent it on the same terms.

Referring again to those reports, they are only from plants now in operation. Why not include more of those which have been suspended or sold? Among the reports from this State, I see none from Newton or Lyons. I think it might prove interesting and instructive if a compilation could be made of the towns which have made the attempt and given it up, with a condensed history of each case.

WM. C. WINDETT,
Secretary and Treasurer What Cheer Elec [illegible]t & Pwr. Co.
What Cheer, Ia., March 2, 1897.

WHEN IS A CENTRAL STATION OVERMANNED?

I AM in charge of a central station operating the apparatus enumerated below. The directors of the plant have inferred that I am employing too much help. In my own mind is the impression that the present force is hardly large enough. All the electrical machines are full loaded and the railway generators run on a constant 25 per cent. overload. I subscribe to The Electrical Engineer and find much of profit to me therein, so I take the liberty of asking its editors their opinion on the subject. Here is the list:

1 pair Corliss engines, 500 h. p. each, 1,000 h. p.; 1 cross-compound Buckeye 600 h.-p. engine, 14 turbines from 100 to 200 h. p. each, 37 turbine bearings, oil cup feed; 1 main shaft, belted to water wheels and engines; 28 main shaft bearings, oil-cup feed; 5 boilers, 3 T. H. type M arc generators; 1 4-circuit arc switchboard, 3 G. E. A.-70 alternators (independent of each other), 3 T. H. D.-6 exciters, 1 switchboard for same, 5 D.-62 T. H. railway generators, 1 switchboard for same, 1 A. T. 100-k. w. three-phase alternator for day lights and power circuits, 1 D.-6 exciter for three-phase alternator, 1 switchboard for three-phase alternator, 2 D.-62 T. H. railway generators; 2 M. P.-90 T. H. railway generators, 1 switchboard for same.

One constant pumping steam pump, run by water wheel when able; 12 station arc lamps trimmed twice daily (24 hours); 3 Lombard water wheel governors whose filters have to be cleaned out on account of sawdust.

The present crew is divided into two watches of 12 hours each, and comprises one chief engineer, two assistant engineers, two firemen, one coal passer, one millwright, two dynamo runners, two oilers, one man to clean water wheel racks, two laborers, fourteen men in all, or seven in each watch. The oilers have to keep the station floors and yard for 100 feet all around clear of dirt.

The railway switchboards are about 50 feet apart and the circuit breakers are out on an average of a dozen times a day.

If you can give me a schedule of work for these men whereby any fewer can be used and run the station properly, I would consider it a great favor. B. C. R.

Our correspondent raises a very important and interesting question and we will be glad to receive and publish replies thereto from central station superintendents.—Eds. E. E.

THE CASE HÆMOGLOBIN OR BLOOD CELL.

If any one proposes to carry forward such an investigation as is illustrated in the blood cell referred to by Mr. W. E. Case, in his recent lecture before the New York Electrical Society, I venture to suggest the utility of a previous careful study of the work of Matteucci, De la Rive and others in the same field. Matteucci especially has gone into this matter, and, it will be remembered, reached the conclusion that organic currents in the body are due to chemical action between muscular fibre and arterial blood in contact with it. His "Traité des Phenomènes Electro Physiologiques des Animaux" (Paris, 1844), will be found quite useful in its warnings against possible errors. For example:

"A liquid which I have been interested in testing in these experiments, in place of acidulated or alkaline water, was blood or its serum. I took some human blood the coagulation of which had been delayed by agitating it as soon as drawn from the vein. I began by assuring myself that the two galvanometer plates plunged simultaneously in distilled water gave no current. We shall see from the following how this was known. Then I withdrew the two plates from the water and at the same instant plunged one into the blood, the other into water like that from which they had been withdrawn. A few seconds after I withdrew both plates, one from the blood, the other from the water, and plunged both in the water. Instantly I obtained a remarkable galvanometer deviation, due to a current which goes in the liquid from the plate wet with blood to the other plate.

"I have wished to vary the experiment so as to place myself, as much as possible, in the same conditions found in making experiments in animal electricity. To that end I took a wick of cotton from 5 to 6 cm. in length, one-half of which I saturated with distilled water, and the other half with blood drawn from a pigeon, agitated as before to prevent coagulation. I used the wick, so prepared to form a communicating arc between two capsules, one filled with distilled water, the other with the same pigeon's blood. Then I closed the circuit with the two galvanometer plates, which when plunged in water had given no current. I obtained a current showing 12 degs. galvanometer deflection, always directed in the wick from the blood to the water.

"I continued the experiment from time to time for three days, always with the same liquid; the current did not vary sensibly either in intensity or direction. If I used acidulated water (sulphuric acid) in place of pure water the current went from the acidulated water to the blood in the wick; that is to say, in the opposite direction from the current obtained between the blood and the water (distilled). The contrary takes place with alkaline instead of acidulated water; that is to say, the current goes from the blood to the alkaline water, as it went from the blood to the pure water.

"The results first stated prove that the greatest precautions must be used in making experiments on animals with a very sensitive galvanometer, and explain a host of erroneous conclusions drawn from ill-made tests."

Mr. Case complains of the sensational articles concerning his lecture in the "yellow" journals; but for these no one will hold him responsible, and, besides, in this he is in good company and is only undergoing the annoyances of which Mr. Edison and Mr. Tesla have at times been victims. He has the consciousness of much creditable priority in the art, for, saving the blood cell, he does not seem to have referred in his lecture to any cell of his own invention which was not patented by him some ten years ago. One of these patents, No. 368,190, Aug. 16, 1887, will be of especial interest to the investigator of cells consuming carbon at low temperature, since it has, among others, the following claims:

"1. The improvement in the art of converting chemical into electrical energy which consists in chemically attacking carbon in a galvanic cell without the application of heat.

"2. The improvement in the art of converting chemical energy into electrical energy, which consists in causing the oxidation of carbon in a galvanic cell without the application of heat."

If this is a pioneer patent it would seem that future discoveries in this field, for the next seven years must conform their prospects to a reckoning with Mr. Case.

G. VOLTA FARADAY.

ELECTRICITY AND THE NAVAL RESERVE.

I was much interested in your editorial in the issue of Feb. 10 entitled "Telegraphic Heroes," and especially in the concluding paragraph which expressed your disappointment that the Naval Reserve devotes so little time to the naval applications of electricity, and so much time to antiquated sailorizing, despite the fact that it contains many very highly educated electrical engineers, who could, as electrical engineers, do the Government valuable service in war time.

In your files for October, 1890, you will find printed a lecture which I gave at Columbia College, proposing the formation of a "Corps of Naval and Military Electricians" as part of the National Guard. The ideas advanced were approved by the body of scientific men of the country, many of whom wrote letters to the Navy and War Departments and to the Governor of New York, and received replies which were favorable in the main. I believe, therefore, that it would be possible to form such a corps; and I also believe (more strongly, if possible, than ever) that such a corps would prove a national benefit.

An idea going a step farther has often occurred to me; and that is, that in the years to come, a distinct Corps of Electrical Engineers will be formed, which will constitute one of the corps of commissioned officers of the regular navy. It is impossible now for naval officers to be competent electricians, just as it is impossible for bankers, doctors or lawyers to be competent electricians, and just as it was for the naval officers of 1840 to be competent steam engineers. Therefore, if the Government wishes to add to its means of warfare the many and powerful agencies of electricity, it may some day form a corps of specialists in electricity, just as it formed a corps of specialists in steam. How distant that day is, no one now can tell.

B. A. FISKE, Lieutenant, U. S. Navy.

U. S. S. Petrel, San Francisco, Feb. 24, 1897.

MORE ABOUT THE BURGLAR AND THE SAFE.

There are one or two points in the late Lieutenant's reply to "Sleuth's" recent letter to the editor, which, if space is permitted, I would like to notice. I think the criticism on the difference between experiment and practice eminently unfair, even coming, as it does, from a superior officer. I think if the gentleman is as well versed as I hope he is, that even he will acknowledge that hundreds of electrical experiments have been perfectly successful in the laboratory, or where all necessary arrangements were made beforehand, and utterly failed when put where what the electrical fraternity calls "bugs" got into them. Hundreds of duplex and quad combinations in telegraphy, any number of telephone schemes, and plenty of electric light systems have been wiped off the face of the earth in this way.

No, I do not contend that 350 or 500 amperes at 40 to 50 volts pressure cannot practically be obtained outside a laboratory. I distinctly stated that large currents had been so taken, but the thieves never told of it.

No one doubts the ability of current to cut a hole into a safe. The point at issue is how will the burglar reach and handle his current without detection. The present (I believe the Holmes system) probably can be beaten for the Lieutenant says it has been. Here is no disputing a prophet, or one who adduces no proof. While I am aware that all this controversy is free advertising for the explosive expert and his system of protection, whatever it may be, there are those who would like more definite information which it is hinted is kept on tap. The supposition that the writer is a detective is far from right. SLEUTH,

Late Fourth Corporal, Indiana Home Guard, and Bell Hanger Electrician.

Vol. XXIII. NEW YORK, MARCH 17, 1897. No. 463.

STEAM BOILER DETERIORATION.

T its object the utilization of carbon in the battery as a cur- HE active work which is now being prosecuted, having for rent producer, is to be encouraged in every way. But while it is going on—and it has been proceeding intermittently for years—we have still to fall back on the old and well-tried steam plant. We hear much of the refinements which have been brought about in the construction of the steam engine, and the large reduction in coal consumption consequent thereon, but we hear comparatively little of the boiler, that useful but much abused adjunct of the present power plant. All things are subject to deterioration and decay, but it seems that the boiler is, among mechanical apparatus, particularly subject to this inevitable law of nature. Anything that can throw light on the causes which work for the destruction and against the efficiency of boilers must be welcome information to all electrical generating plants. We are pleased, therefore, to note in the Engineering Magazine for March, an excellent essay by Mr. Albert A. Cary, in which that gentleman discusses in a very lucid manner the cure for corrosion and scale from boiler waters.

It must be apparent that if absolutely pure water were available from natural sources for boiler use, practically no precautions whatever would be required in the care and handling of a boiler, so far as the quality of the water is concerned; but unfortunately such is not the case. It is even erroneous to suppose, as Mr. Cary points out, that if the boiler be fed by good dinking water it must necessarily be good for boiler use, a delusion which many have indulged to their cost. Indeed, Mr. Cary goes so far as to say that no pure water is obtainable from natural sources, even rain water being found to contain more or less impurities, it being only a question of degree, although, of course, rain water is among the purest natural sources. Unfortunately, however, the supply from this source is usually inadequate to the demand, but when used arrangements should be introduced to free the water from the dust, soot and other dirt which accumulate on roofs, and it is advisable even to allow the first rain that falls to run to waste. In order to show that even pure water, such as that obtained from melted ice in Switzerland, and that supplied to the city of Glasgow, Scotland, which is of exceptional purity, may do harm, Mr. Cary instances the fact that the pitting of boilers gives a great deal of trouble to the latter city, the result being the perforation of the boiler as though it had been drilled. Experiments have shown that pitting occurs when gases are found dissolved in the water, oxygen and carbonic acid gases being the most active destroyers, especially when present together. The explanation of the action on boilers is not an easy one, yet that the result is due to their presence is no longer a matter of doubt.

It has long been suggested that the corrosion of boilers was due to electrolytic action set up between the impurities in the iron (occurring at small points) and the iron of the boiler itself; the iron being electro-positive to the impurities, gradually disappears, while the impurities remain unaffected to further this destructive action. If this is a correct explanation, it has been argued that it may be overcome by suspending zinc in the boiler, and connecting it carefully with the boiler shell by copper wire. The zinc being electro-positive to iron will disappear gradually, and in so doing will protect the iron. Mr. Cary believes, however, that the gas in the water is all sufficient to account for the trouble.

In treating of the general corrosion of a boiler, that is, the gradual wasting away of its parts, Mr. Cary points out the necessity of rigid examination, which can only be accomplished by actually drilling holes through the plate, as even experienced inspectors may be deceived by surface appearance. As to the cause of this general corrosion, the electrical theory seems to be the one most generally put forward. In regard to the application of zinc to prevent the wasting away of the iron, we are glad to note that Mr. Cary lays particular stress upon the fact that several conditions must be fulfilled. In the first place, either the water itself must be a good electrolyte, or must be made so by the addition of suitable material, such as salt. Another, and this is of paramount importance for the successful application of zinc, is that the electrical communication between the zinc and the shell must be not only good but of permanent nature, and not affected by the local action which might interrupt the circuit. It is interesting to note that so much faith has been placed in the electrical remedy for boiler deterioration that Mr. Cary cites an instance of a concern in Cardiff, Wales, that has gone so far even as to supply the current to its boiler from a dynamo, ana it is claimed that superior results are obtained by reversing the current periodically. It is claimed that this reversal makes the suspended plate electro-negative to the shell to facilitate the disintegration of the scale and hasten the mechanical action of the hydrogen in flaking it off, and also to prevent the polarization of the shell and tube. Mr. Cary prefers to see these claims proved by more extended use before accepting it as good practice.

Regarding the methods employed for preventing the formation of scale, Mr. Cary has done a good service by pointing out the dangers which may arise by introducing kerosene into boilers for this purpose, a practice which is widespread in the United States. He shows that serious corrosion is often followed by the use of this material, and has puzzled many to account for it; but the reason is not hard to seek, when, as Mr. Cary points out, it is known that sulphuric acid is employed in the manufacture of kerosene in order to purify it. If all of this acid is not removed, the oil, when in the boilers, volatilizes and passes off with the steam, while the acid remains behind, concentrates as additional oil is added, and attacks the iron. As an antidote, Mr. Cary cites a case where kerosene is varied with an alkali, such as the carbonate of soda, on alternating weeks, and trouble has thereby been avoided. Oil and grease are also apt to give trouble due to the presence of mineral and vegetable acids.

Enough has been said to demonstrate the importance of the proper selection of feed water for power plants. Frequently, of course, there is no choice in the matter and waters have to be used which are, in themselves, totally unfit for steam making; but if means must be employed to purify them, the proper selection of the material and methods of purification should command the closest study in order to avoid excessive boiler repairs, or even destructive explosions. We commend Mr. Cary's article to all interested in steam engines for whatever purpose.

THE STOCK TICKER SERVICE.

THE New York Stock Exchange, and other legitimate exchanges, appear to be in constant difficulties over the control of the quotations made on their floors. What they wish chiefly to do is to prevent these quotations from falling into the hands of the bucket shops, their underselling competitors, but the policy or plan of cutting off never seems to succeed for very long periods. Just now the New York exchange is dealing again with the problem of the extermination of the gambling bucket shops, and out West serious difficulties have also arisen. There are two principal quotation companies in this city, and the best legal opinion apparently is that the exchange cannot confine itself to the giving up of the quotations to the one company that it controls. In Kansas City, a decision has just been rendered in the United States Circuit Court, in keeping with one in Chicago, practically compelling the Western Union Company to furnish such quotations without discrimination. The Chicago Board of Trade has sought to limit the delivery of its quotations to its members and their patrons, but the effect of such decisions is to render the quotations public property to the extent that all may get them who are willing to pay for them from the telegraph company.

The extent of the injury done by the bucket shops to the regular exchanges is not easy to estimate. It is said they deal certainly in not less than 1,000,000 shares daily in this city; the stock exchange has of late been doing a business on some days of less than 100,000. The allegation is made that the bucket shops cheat the customers by employing a "fast" and a "slow" ticker, the proprietor having the exclusive benefit of the "fast" one. It would strike most electricians as an impossibility to carry out this scheme with the two instruments on one circuit; but even if there are two services, they are likely to deliver their news pretty closely, and the customer must indeed be a fool who did not discover that he was the victim of such a "thin" device. It needs only the ordinary amount of human, ineradicable love of gambling and excitement to explain the popularity of the bucket shops, which, with their facilities for cheap betting in these days when the police close up at once the gambling hells, afford an opportunity sought after by a great many people. It is generally supposed that in Monte Carlo, big or little, the bank wins in the long run, even with an honest, "square" game, and thus, too, without loaded dice in the shape of fast and slow tickers, the bucket shops may still win handsomely and pocket fat commissions, even at half the regular stock exchange rate of one-eighth of one per cent. The situation is one of great interest electrically, as there are not less than from 2,000 to 2,500 tickers in use in this city, and the tendency is to increase their employment in a variety of ways not contemplated upon their first introduction many years ago, although the telephone has probably checked such growth.

A LAMP-TESTING BUREAU.

THE plan for a lamp-testing bureau put forward by the National Electric Light Association and published in our pages last week has obvious merits. We intimated then our belief that some plan of the kind had already been tried, and we are now able to state, as the result of further inquiry, that such an organization was established last year at the Harrison lamp works of the General Electric Company by the Association of Edison Illuminating Companies, as the result of negotiations started while Mr. J. I. Beggs was chairman of the association's Executive Committee, and consummated under Mr. Edgar's chairmanship. The importance of this can be well understood, as the Edison Association represents the largest consumers of lamps in the country. Under this plan, such companies as those of New York, Boston, Chicago, Philadelphia and Brooklyn, have tests, by sample, of their lamps made by their expert, Mr. W. S. Howell, and it is obvious that other Edison licensee companies can also enjoy the advantages of the system, and will gradually come in. The lamps are tested in a separate department, and a method of bonuses and penalties, dependent on quality, governs the price to the purchasers.

We are informed that the plan is working admirably, and it can readily be understood that it inures to the decided benefit of the consumer and results in steady improvement in the lamps. This being the case, and the proposed plan of the National Electric Light Association being modeled or copied after that of the Edison Association, it would seem that, perhaps, some arrangement can be come to that would permit co-operation, so far as purchasers of Edison lamps are concerned; but it would also appear that some other plan would be necessary where the purchases were made from other lamp companies, especially those who are "independent" and outside the pool.

STORAGE BATTERY ENGINEERING PRACTICE.

THE introduction of one large storage battery plant after another in central stations and of smaller isolated plants all over the United States, indicates unmistakably that gradually, but surely, this type of apparatus is receiving the patronage which it deserves. From frequent inquiries which we have received, it has become evident to us that there existed a woeful lack of knowledge on the methods of handling storage batteries for the many purposes and situations to which they can be applied. Possibly it may be due to this fact that the battery itself has been so long allowed to remain in the background. The recognition of this fact has determined The Electrical Engineer to lay before its readers the information which will enable them to gain a knowledge of the uses and workings of storage batteries for every purpose to which such batteries have thus far been applied. To this end it has begun, in this issue, a series of articles which will take up and treat the subject systematically in all its phases. The author of the series, Mr. Joseph Appleton, has had long and varied experience covering practically the whole period of existence of the modern storage battery. His articles embody results which have been found best in practice, and which have been, so to speak, the outcome of successful experiments. This series of articles is not intended in any way to treat of the manufacture of storage batteries or to describe historically the various types which have been brought forward. This has been done frequently and a history of the art in this respect can be found in numerous excellent works. The present object has been to place before the readers of The Electrical Engineer the best modern practice in the handling of storage batteries, after they leave the manufacturer and pass into the care of the engineer.

ACCORDING to the Detroit "Free Press," a well-known engineer in that city has been advocating free electricity as an even greater boon to the populace than free water. An abundant, cheap supply of either is undoubtedly a good thing, but we cannot quite grasp the idea of getting them for nothing. How is it done? Water distribution in most cities is an expensive thing, and electricity is a manufactured article. Now, somebody in the long run has to foot the bills, and we are not aware that the rest of the country is willing to do this for Detroit; so that the citizens must pay for these things themselves, if not at so much per gallon or per kilowatt, then in the shape of local taxes. We do not see how a thing can be free that people are taxed for, unless by a pretty little process of confiscation which would throw the burden on property and labor. How much property and how much labor there would be left in Detroit after, say, ten years of free water and free electricity, it is, perhaps, not difficult to imagine. Detroit is a city of many attractions, but her taxpayers would all probably have sought some other place at the end of the period.

TOWER lighting by arcs is still practiced and is often proposed, for new installations, but does not appear to make much headway. It has recently been mooted in connection with the municipal plant for Des Moines, Ia., but it occurred to one of the aldermen to write to the mayor of Davenport, Ia., asking why the tower system was given up in that city some years ago. The mayor's reply is rather emphatic and amusing: "Because," he says, "we did not consider it legitimate expenditure to attempt to light the road to heaven at the expense of the citizens of Davenport." He adds that it is a nice thing to talk about, but a poor substitute for surface lighting as furnished by pole light. That seems to be about the general idea, although there does not appear any good reason why reflectors could not be brought into play to aid in throwing the light downward from inverted arcs. It is possible the plan has been tried and found wanting.

THE resources of electricity are varied, as some burglars discovered the other night, at Providence, R. I., where, after cutting the telephone wires, they proceeded coolly and calmly to break into the Colwell mansion. They were just about settling down to business when Mrs. Colwell appeared at the head of the stairs and pushing a button illuminated the whole house, so that they could the more comfortably do their work. But if there is any one thing objectionable to the burglar it is to be exposed to identification, and in this case, the gang, instead of waiting to enjoy the aid of the light, fled headlong before its beams. What with telephones, burglar alarms, concealed switches and electrified doorknobs, the honest burglar now has a hard time earning his livelihood.

A GREAT deal of feeling, and with good warrant, is manifested from time to time by working men whose product has to meet the competition of cheap goods made by convict labor, and who argue that there are plenty of things for criminals to do for the benefit of the State, when under arrest, besides underselling honest men. A new aspect of the problem is presented at Leavenworth, Kan., where Mr. L. M. Erb, the manager of the Leavenworth Electric Railway, has closed a contract with the directors of the Kansas Penitentiary there for current. Mr. Erb is to build an extension line of road, and put in the plant, but the penitentiary mines the coal already and has the labor, so that the power will, it is said, be very cheap. It is a curious arrangement, and we should imagine that the local labor organizations will have, as usual, an emphatic opinion to express on the subject.

ELECTRIC LIGHTING

CONDUCTIVITY OF INCANDESCENT CARBON FILAMENTS AND OF THE SPACE SURROUNDING THEM.[1]—I.

BY JOHN W. HOWELL.

THE first part of this paper, which relates to the conductivity of carbon filaments, is in the nature of a discussion of a paper read before the institute by Prof. Anthony, at the May meeting in 1887.

Prof. Anthony spoke of a change from negative to positive of the temperature co-efficient of some carbon filaments which he had observed. Prof. Anthony stated that this change did not occur in all filaments, and that he was unable to explain the circumstances under which it did occur. Prof. Elihu Thomson, in his discussion of Prof. Anthony's paper, said that he had observed the same phenomenon, but had not investigated it sufficiently to explain its cause.

I made a set of ten lamps with various amounts of treatment, all made from similar base filaments. These lamps had filaments the resistances of which, when cold, were 90, 80, 70, 60, 50, 40, 30, 20 and 10 per cent. of the cold resistance of the original base. I found, upon plotting the curves of these filaments, that the untreated filament fell in resistance as it was made hotter, and that this fall continued to the highest temperature at which I dared run it.

The slightly treated filament fell in resistance more rapidly than the untreated filament at first, and less rapidly as the high temperatures were reached, its curve finally rising above that of the untreated filament. As the amount of treatment is increased, the curve falls more and more rapidly at first, and less rapidly at the higher temperatures. When we reach the filament treated to 50 per cent., we find that it falls rapidly to about 50 per cent. of its cold resistance, and remains practically constant at higher temperatures. The curves of filaments treated to less than 50 per cent. all rise after reaching their lowest point, which is reached at about 50 per cent. of their three watts per candle voltage. See Fig. 1.

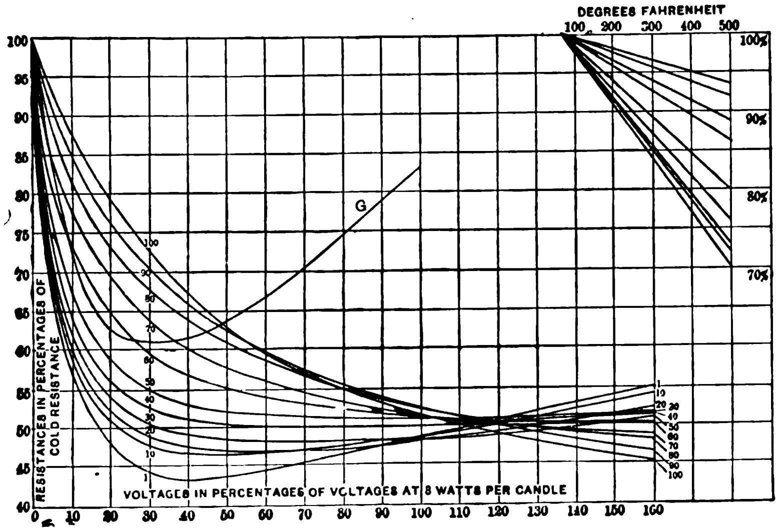

FIG. 1.—CURVES SHOWING CHANGES OF RESISTANCES OF LAMP FILAMENTS WITH VOLTAGE AND TEMPERATURE.

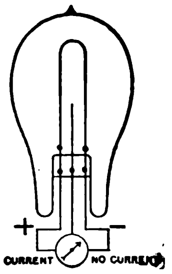

FIG. 2.

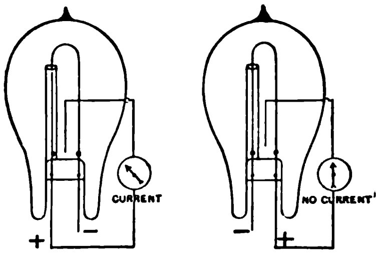

FIG. 3.

These curves show the changes in resistance of these filaments. The ordinates are percentages of the cold resistances of the various filaments, so that all curves start from the 100 per cent. mark. The abscissæ are percentages of the voltages at which the various lamps take three watts per candle. The bottom curve on this sheet illustrates the resistance curve of a carbon filament which had been treated to about one per cent. of its original resistance. This made a filament which was nearly all treatment. This curve shows an increase in resistance from its lowest point to the last point obtained, of about 25 per cent. The cold resistance of the filaments, after being measured was found to be the same as before any measurements were made.

I then obtained untreated base filaments from as many kinds of amorphous carbon as I could obtain, and plotted their resistance curves. I tried filaments made of bamboo, silk, cotton, cellulose (made by the ordinary squirt process), tamidine and paper. All of these base carbons gave the same curve, and all of them continued to fall in resistance as long as I was able safely to increase the temperature.

I was entirely unable for a long time after making these curves to come to a satisfactory theory regarding them. The reverse curve is not caused by changes in the characters of the surfaces of the carbons, due to emissivity, because no corresponding changes in emissivity occur.

I made observations upon untreated and heavily treated filaments, to see if they acted differently in regard to their expansion with heat, thinking that possibly the changes in the resistance curve may have been caused by a change in the expansion curve with temperature. These observations were not very refined, being simply observations made by means of a telescope, but they showed clearly that all of the carbons expanded with heat, and apparently there was no difference in this respect. The curve marked G is the resistance curve of an Edison graphite filament; it does not fall as the other curves, and rises much more. The resistance of this filament, after the measurements had been made, was just the same as before they were made. This indicates quite clearly that our calling the treated carbon "graphitic" is correct, and that the change in the resistance curve of treated filaments is due to the graphitic nature of the layer of carbon which is put on during the treating process.

The second part of this paper, which relates to the conductivity of the vacuous space surrounding incandescent filaments, may be considered as a discussion of the paper upon the "Edison Effect" in incandescent lamps, which was read before the Institute by Prof. Houston, in October, 1884, and which was the first paper read before this society.

"Edison Effect" is the name given to the effect produced by those currents, first observed by Mr. Edison, which pass from one leg of an incandescent filament across the vacuous space to the other leg, and which can be observed by connecting a galvanometer between the positive lamp terminal and a wire sealed into the bulb and projecting into the vacuous space.

Fig. 2, which is taken from Prof. Houston's paper, serves to illustrate Mr. Edison's original experiment. The galvanometer indicates a current flowing from the positive lamp terminal through the galvanometer and third lamp wire, and through the vacuous space to the negative leg of the incandescent filament. If the external connection of the galvanometer be changed from the positive terminal to the negative terminal, no current will flow through the galvanometer. This effect can be observed in the most highly exhausted lamps. A lamp so highly exhausted that it shows no glow when tested with an induction coil, giving a spark three-quarters of an inch long, will allow a current sufficiently large to show plainly on a not very sensitive galvanometer, to pass through its vacuous space. This current increases as the temperature of the filament is increased, but in a well exhausted lamp is never greater than a very few milliamperes, when the lamp is burned at about 2½ watts per candle.

---

[1] Read before the American Institute Electrical Engineers. Abstract.

In 1884 Mr. Preece secured from Mr. Edison some lamps having wires sealed into the bulbs, and read a paper before the Royal Society describing some experiments made upon them, illustrating the "Edison Effect."

Prof. Fleming read a most elaborate paper before the Physical Society of London, in March, 1896, upon this same subject. Prof. Fleming's experiments proved that in well exhausted lamps the vacuum is not a conductor in the ordinary sense of the word, and that the current which passes through it is carried by negatively charged molecules, which pass constantly from the negative leg of the incandescent filament to the positive leg and to any inserted wire, thus bringing the inserted wire to the same potential as the negative leg. Prof. Fleming also proved that these molecules pass in straight lines, and that their passage is completely or almost completely stopped by a glass or mica screen placed between the negative leg and the inserted wire. The following experiments serve to illustrate these effects:

Fig. 3 shows a lamp having a glass tube surrounding one leg of the filament, and a wire sealed in the side of the bulb. which projects into the center of the vacuous space. When the leg of the filament which is in the glass tube is made positive, and the filament heated to about a 2½-watt candle temperature, the galvanometer, which is connected between the wire and the positive lamp terminal, shows a strong deflection, but when the leg in the tube is made negative the galvanometer, being as before connected between the wire and the positive lamp terminal, shows no deflection.

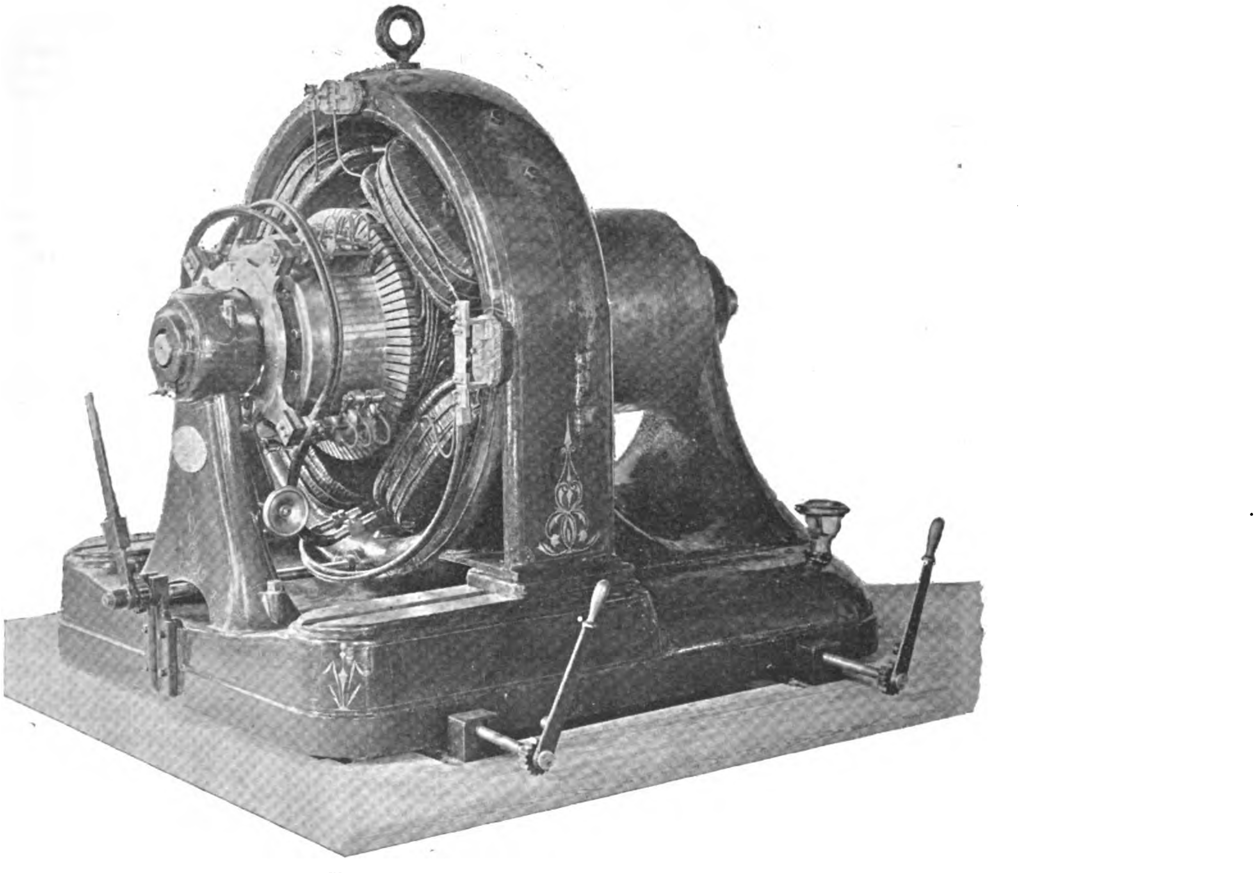
THE IMPROVED CARD GENERATORS.

The accompanying engraving illustrates the improved generator manufactured by the Card Electric Company, of Mansfield, Ohio, which embodies a novel and convenient method of moving the pole frame and field magnets away from the armature, so that inspection can be readily effected.

The manner in which the pole frame and field magnets are mounted on the base and the convenience it affords for inspecting the armature or field coils, can readily be seen. The brackets for supporting the pole frame have tongues cast on them on the under side, which are planed to fit in the grooved slides on each side of the base. On the front of the base is a bracket with a screw, which passes through a nut fastened to the bottom of the pole frame. With the ratchet lever the field core or frame and field magnets can be slid forward on the base, completely uncovering the armature. If it is desired to take the field core or frame entirely from the base, two pieces of timber, made level and placed at the end of the base, and a crowbar, are all the tools necessary.

The above method is applied to direct-driven as well as belt-driven generators. A number of the Card generators having this particular feature, are at present being installed in various localities.

The armature is supported on three self-oiling and self-aligning bearings; the two at the pulley end are cast together in a very rigid form.



The Card Improved Generator

THE JACKSONVILLE, FLA., MUNICIPAL PLANT.

Jacksonville, Fla., has a somewhat different story to tell of its experiment with a municipal electric light plant. A report, recently presented, repeats the assertion in a previous report, that the city is much better lighted than it had been under the contract system, and at a much less expense, while the charge to private consumers is so small that the requests for service are far beyond the present capacity of the plant. Not taking into consideration interest on the cost of the plant and a sinking fund for retiring the bonds that represent its value, but taking the difference between the receipts from commercial lighting and the operating expenses added to the construction of new lines, etc., and the actual cash cost of lighting the city varied from $4 for each arc light in January to sixty cents in September. There is a different showing, however, when allowance is made for interest, sinking fund, and depreciation. The plant represents an expenditure of about $100,000. Calculating the interest at 5 per cent., adding a like amount for a sinking fund and estimating depreciation at 5 per cent. (a rather low estimate), makes a total of $15,000. As the Jacksonville Citizen shows, the net profits from the plant will not be sufficient to meet this sum annually, and unless the income shall be increased, other means must eventually be devised to pay the original cost of the plant, and to meet at least a part of the annual interest on the bonds.—New York Evening Post.

THE MUNICIPAL PLANT AT LISBON, IA.

Mr. W. H. Runkle, Mayor of Lisbon, Ia., and superintendent of the electric light and water plant, sends us a revised report of that plant of later date than the one included in Mr. Winchester's report on municipal plant data printed in our issue of Feb. 17. "Fourteen 2,000 candle-power arcs on streets, eight 1,200 candle power arcs in commercial service, 600 16 candle power incandescents in use, a combined water and light plant. The 14 arcs are counted at $600 for the year, and a very low rate is charged for all commercial and residence lighting. Earnings of the plant for the year ending Feb. 28, 1897, $2,517.95; running expenses for both water and light plants, not including the interest or depreciation of plant, $1,998.88; net earnings over income, $519.07. I think the city should in each case own its plant and service on streets and supply its citizens at a normal cost. Can be managed economically by a single superintendent at a small cost."

LITERATURE

POWER DISTRIBUTION FOR ELECTRIC RAILROADS. —By Dr. Louis Bell. New York, 1897. Street Railway Publishing Co. 268 pp., 6 x 9 in. Ill. cloth. Price, $2.50.

There is, perhaps, no system of electrical distribution which has given rise to more disappointment than has electric railroad work. While the principles do not differ from those involved in other systems of electric distribution the undetermined factors which are entirely beyond the control of the engineer require a special equipment and the exercise of considerable judgment, not to say the faculty of guessing. Still there is enough real engineering in plants of this nature to make it absolutely necessary to base the main work on established principles.

It is somewhat in this light that the author has treated the present subject. He begins by a description of the fundamental principles which apply to the laying out of electric railway conductors, and shows how the center of gravity method of calculation may be applied to the location of the centers of distribution, and taking into account also the variations of load, their nature and magnitude. He then takes up the return circuit, describing the methods that have been employed for this purpose, and showing how troubles may be avoided, and energy saved by proper attention to the bonding of joints, etc. Direct feeding systems are then treated in extenso, showing where re-enforcements should be made at special points. Here we find a valuable chart, giving the area and weight of copper required for transmitting 100 amperes 25,000 feet and less at 50 volts loss, with various constants for track return. An attentive study of this chart will show where many mistakes have been made by designers of railway distributing systems. But, as the author says, the art of feeder design is one that calls for great finesse, and cannot be reduced to formulæ that will be of use in anything save special and unusual circumstances. Succeeding chapters are devoted to the important topics, of special methods of distribution by means of boosters, 3-wire system, etc., sub-stations, and transmission of power from the latter.

Although somewhat in advance of the times the author has very wisely included a good review of the present status of the alternating motor as applied for railway work. He shows the advantages and disadvantages of the various types of these motors for this purpose, but admits that, so far as polyphase motors are concerned, none of the methods of regulation as yet devised is quite the equivalent of the series parallel controller employed at present, that is, so far as efficiency is concerned. The lines of work for which alternating motors are most needed, in his opinion, are the long interurban and similar lines, where the need of highly efficient control at very slow speed is not so great as in ordinary street railway work. He also calls attention to the necessity of at least two trolley wires for polyphase induction motors, and to the bad effect of lagging current in this type of motors; although, of course, this difficulty decreases, the higher the speed of the motor in large machines of this type.

In order to give a concrete picture of the various systems of distribution, the author has worked out an actual example, comparing the following four systems: 1. Direct supply from two symmetrically placed stations. 2. Supply from a single station with boosters. 3. Supply from one station with a rotary transformer substation. 4. Supply from a single station by alternating currents and static transformers. These calculations show that the annual charges for the three systems first mentioned are practically identical, while No. 4 has an advantage over the others of about 16 per cent. The details of these calculations are highly interesting and should be studied by all whose work lies in this direction. Chapters on interurban and cross-country work and fast and heavy railway operation conclude the work.

In this brief notice much that might have been profitably dwelt on, had, of course, to be passed over, but we have rarely seen a work in which there was contained so much real meat and intelligent discussion as in the one before us. It is full of practical information and evidently written by one who is a thorough master of his subject. The only serious criticism we have to offer is on the entire absence of an index.

LEGAL NOTES

WISCONSIN ELECTRIC MEDICAL COLLEGE.

A special dispatch from Madison, Wis., of March 8, says: The Secretary of State this morning received notice of the dissolution of the articles of incorporation of the Wisconsin Electric Medical College. This institution has proceedings pending against it brought by the Attorney General to cancel its incorporation on the ground that it is not properly fitted to give medical education.

ENLARGING THE SCOPE OF LIGHTING COMPANIES.

Assemblyman Scherer has introduced in the New York Legislature a bill providing that electric light and power companies incorporated under special laws shall have the right to operate by electricity railroads four miles in length in cities of the first or second class, and twenty-five miles in length elsewhere. They shall also, except in the class of city mentioned, have the right to acquire property and franchises of other railroads not more than twenty-five miles long operated by electricity. The bill also provides for the acquiring of the capital stock of waterworks corporations by electric light and power companies when the latter furnish the former with power.

THE DECISION ON HEATER SWITCHES.

In reference to the decision on heater switches noted in our issue of February 24, 1897, it would seem that the broad construction put upon the decision of Judge Coxe by the American Electric Heating Company, is not fully borne out. We have received from the Consolidated Car Heating Company a copy of Judge Coxe's decision. According to the latter, the only claim involved is the ninth, which reads as follows:

"In an electric heating apparatus having heating conductors or sections adapted to be connected in different ways with the supply conductors, a switch for controlling said connections, and an indicator operated by the movement of the switch to indicate how the connections stand."

Judge Coxe rules that the patent has been infringed, but states that "the defendant has only to drop one element of the combination and it will be absolutely safe from attack."

The decision has been appealed from by the Consolidated Car Heating Company, who inform us that it affects nothing but the use of a particular kind of indicator on a switch, and that it has nothing to do with the electric heating system, or with the switch itself, or the combination, but merely the indicator; and they state that if the indicator is changed, infringement is avoided.

UNWILLING TO CRIPPLE CORPORATIONS.

The South Carolina Legislature has killed bills putting telegraph and express companies under the control of the Railroad Commission, providing for a labor commission, regulating hours of labor on electric roads, and several others tending to bind or hamper the management of corporations.

HOUSE AND HOME is the subject of the next exposition in Grand Central Palace, to be held April 3 to 28. The proceeds are to be devoted to a charitable purpose. One of the features will be a Twentieth Century Electrical Kitchen, and many other electrical things will be included. The general manager is Daniel Browne, 34 Park Row, N. Y.

PERSONAL

KINSMAN & KNUDSON.

F. E. Kinsman.

IT gives us pleasure to announce the recent formation of a co-partnership between Mr. F. E. Kinsman and Mr. A. A. Knudson, both very well known in the art, and both men of extended experience. Mr. Kinsman's experience, as is well known, dates back to the earliest inception of the telephone business. As formerly published in these columns, his early experience with the telephone was quite a remarkable one. He designed the first central office telephone system built. His Boston experience, which consisted in the conception and working out of a central office system for another purpose than the telephone, before that valuable instrument was made practical, and his subsequent unique experience in adapting it to telephonic uses, justified his being retained by the Gold & Stock Telegraph Company of this city during the preliminary and actual arrangements connected with the organization of the American Speaking Telephone Co. He was sent to Chicago by the late George Walker, vice-president of the Gold & Stock Co., in the winter of 1877, to assist in the establishment of the telephone business in Chicago, under the auspices of the Western Union Telegraph Co. and the American Speaking Telephone Company. As early in his Chicago experience as the first part of 1878, he invented the "multiple switchboard," now so important in telephone business. He interested the late Gen. Anson Stager in this invention to the extent of selling him one-third interest in his invention, and, later on, he sold to the Western Electric Company the remaining two-thirds, which they amalgamated with the inventions of others, and upon which their extensive switchboard business of the present day is based. Through Gen. Stager's influence, Mr. Kinsman returned to New York, where he has since been intimately identified in the broadest sense with the growth of almost every branch of the electric business. During the years of 1879 and 1880, he was superintendent of repairs and attachments for the Metropolitan Telephone Company. Resigning from this position, he organized the firm of Kinsman & Tobey, whose business was soon merged into that of the Electric Construction and Supply Company, of which Mr. Kinsman was president until the year 1889, when he sold his interest in that company for the purpose of engaging in railroad and block system work. The Electric Construction and Supply Company's history, under Mr. Kinsman's management, is the record of the commercial introduction in this country of arc lamps on low tension circuits, as Mr. Kinsman was the first to burn arc lamps on incandescent circuits in this country. His early predictions in regard to this class of lamp have been fully verified, as more than 100,000 of them are now in use in this country alone. The Kinsman railroad block system is unique, and fully bears out his reputation as a practical designer and engineer. For long and practical experience in electrical and railway matters, Mr. Kinsman stands pre-eminently qualified, from every point of view, as a conservative and safe adviser. To those who knew him in his past experience as a construction and supply man, little need be said. He brings to this new enterprise not only the experience of an engineer and inventor, but what is, perhaps, of more importance to the investor who seeks his advice, is his long experience as a manager, financier and employer, qualifications, all of which are seldom found in an engineer.

A. A. Knudson.

Mr. Knudson's experience in electrical matters dates back to 1872. He was an inspector in the "ticker" service of the Gold & Stock Telegraph Company, when Gen. M. Lefferts was president. In this position, his inventive ability began to show itself, and in 1873, he invented and patented the first self-winding "stock ticker," which he sold to the Western Union Telegraph Company, and which, of late years, has been brought into common use. He has also taken out a considerable number of other patents for improvements in printing telegraphs, nearly all of which have been purchased by the Western Union Telegraph Company, and form no insignificant portion of the patents now held by the Gold & Stock Telegraph Co. In 1876, Mr. Knudson was made inspector in the private line department of the Western Union Telegraph Company, and had much to do with the early and successful work done by that department. He was also prominent in the private line department of the American Speaking Telephone Company, and afterward with the Metropolitan Telephone and Telegraph Company (now known as the New York Telephone Company), from whose service he resigned to engage in business for himself in 1883. The "K. K." wire, and other well-known brands of telegraph and electric lighting wire, were invented by him. No less an authority than Prof. Perrine, in an article in these columns on insulated wire, some time ago, gave Mr. Knudson the credit of being the originator of weather-proof wires. The so-called "K. K." patents date as far back as 1880, and were the first attempt in this direction. Mr. Knudson's experience in electrical matters in Canada, Nova Scotia and New Brunswick, is known by the fraternity to have been extensive and varied, covering several branches of electrical science. He was the first to introduce the alternating electric light in Halifax, and was afterward general superintendent of the telephone companies in Nova Scotia and New Brunswick. Then as general superintendent of the Canadian Electrical Exposition, in St. John, N. B., he won much credit and many friends. Later he was manager and electrician of the Eastern Electric Company, afterward called the Consolidated Electric Company (which combined the Electric Railway, Arc and Incandescent Lighting of that locality). His experience with electrical enterprises in Mexico, added much to his experience in matters relating to export and foreign usages. He has frequently been called as expert in patent suits, relating to electric matters, and has several times been called to Albany by members of the State Legislature, and consulted by them in relation to electrical subjects. He is one of the oldest members of the New York Electrical Society, and has frequently appeared before it with papers of special interest on electrical matters. His latest invention, the ampliphone, was recently illustrated in these columns. Both Mr. Kinsman and Mr. Knudson are full members of the American Institute of Electrical Engineers, and now offer their combined experience as experts and consulting or supervising engineers in all classes of electric work. They report, as a recent engagement, their selection as experts in an important municipal case in a neighboring city. They have established their headquarters in the Manhattan Life building, 66 Broadway, New York. We are indebted to these gentlemen for the biographical data given above.

MR. W. B. SOMERVILLE, the superintendent of the Press Bureau of the Western Union Telegraph Company, New York City, has been dangerously ill the past few weeks, but is now, we are glad to say, safe and convalescent.

MR. W. G. LEVISON gave a lecture recently with experiments, before the department of physics of the Brooklyn Institute on phosphorescent and fluorescent light.

MR. EDGAR T. BRACKETT, member of the New York State Senate, has been elected president of the Saratoga, N. Y., Gas, Electric and Power Company.

MR. J. E. LOCKWOOD, of Detroit, Mich., was in New York last week, looking into matters of recent inventive and engineering interest.

CINCINNATI, O.—The new electrical club has elected T. J. Creaghead, as president, W. M. Venable, as vice-president; Hugo Damer, as secretary and treasurer, and L. E. Bogen, as librarian.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 9, 1897.

Alarms and Signals:—

CAR ANNOUNCER. W. A. Heckard & D. Ogden, Columbus, Ind., 578,402. Filed May 14, 1896.

Adapted for use by suburban residents, whereby they may be notified of the approach of a train which they may desire to take.

DEVICE FOR OPERATING SIGNALS. S. S. Bogart, Schraalenburg, N. J., 578,442. Filed Feb. 7, 1895.

The weight of the signal is adjusted to be raised by a magnet of little power, and is lowered by its own weight aided by a counterbalance.

Connectors, Conduits and Insulators:—

PIPE. H. B. Hilgeman, St. Louis, Mo., 578,333. Filed Dec. 10, 1896.

A pipe having a glass lining and a layer of cement surrounding the glass.

Electro Therapeutics:

ELECTRICAL CANE. W. N. Sherman, Merced, Cal., 578,471. Filed April 2, 1896.

A cane combined with an electric battery.

ELECTRO-THERAPEUTIC SYRINGE. J. D. Rively, Pittsburg, Pa., 578,611. Filed April 24, 1896.

Lamps and Appurtenances:—

MANIPULATING DEVICE FOR INCANDESCENT LAMPS. J. J. Dunn & J. W. Regan, Boston, Mass., 578,394. Filed March 9, 1896.

For removing lamps difficult of access.

ELECTRIC LAMP POST. J. Buckner, Boston, Mass., 578,595. Filed June 8, 1896.

Comprises a tubular metallic base section having a tapered socket, an elongated wooden section having a metallic lamp holder at its upper end and a tapered shank at its lower end formed to enter the socket, and a hood affixed to the wooden section above the metallic section.

Measurement:

ELECTRIC METER. E. Thomson, Lynn, Mass., 578,430. Filed Aug. 26, 1889.

Comprises armature coils carrying a practically constant current, field magnet energizing coils in which a rotating armature moves, and an accessory field circuit supplied with current from any suitable source.

Miscellaneous:—

THERMAL CIRCUIT CLOSER. H. F. Maxim, Norfolk, Va., 578,-345. Filed May 29, 1896.

Comprises two parallel expansible bars of different strength, and each adapted to be connected with one terminal of an electric circuit, and a relatively stationary contact arranged in the path of one of the bars and adapted to be connected with one terminal of an electric circuit.

ELECTRIC GAS LIGHTER. F. N. Pike, New York., 578,420. Filed March 11, 1896.

Details of construction.

PROCESS OF AND APPARATUS FOR SIMULTANEOUSLY PRODUCING AMMONIA, SODIUM HYDROXID, AND CHLORIN. C. Kellner, Vienna, Austria-Hungary, 578,457. Filed Feb. 24, 1896.

The process which consists in decomposing the chlorid, forming an amalgam, and imparting to the amalgam a gyrating motion toward a central point.

MAGNEIC APPARATUS. A. Boetcher, Philadelphia, Pa., 578,673. Filed May 31, 1895.

Magnetic apparatus by which a long movement of the armature is attained for use in throwing switches, signals, etc.

PROCESS OF AND APPARATUS FOR PRODUCING CALCIUM CARBID. E. R. Whitney, Manchester, N. H., 578,685. Filed May 25, 1896.

Consists in subjecting a moving mixture of pulverized lime and pulverized charcoal to the action of a number of separate electric arcs proceeding from charcoal electrodes and crossing each other.

COIN-FREED APPARATUS FOR ADMINISTERING ELECTRICITY. K. Rudolph, Poessneck, Germany, 578,526. Filed March 18, 1896.

Comprises two springs arranged below the slot through which the coin is dropped, a lever mechanism operated by the movement of one of the springs under the weight of the coin, and connections for controlling and operating the electric circuit.

PAPER REGISTERING MACHINE. T. C. Dexter, Pearl River, N. Y., 578,549. Filed Aug. 9, 1895.

Details of construction.

Railways and Appliances:—

CONTACT FINGER FOR ELECTRIC CONTROLLERS. E. C. Parham, Johnstown, Pa., 578,464. Filed Nov. 18, 1896.

Comprises a magnetizable finger member, means for magnetizing the member, and a contact carried by the member and carried between the poles thereof.

TROLLEY SUPPORT. E. Blamey, Jersey City, N. J., 578,539. Filed Dec. 4, 1895.

A yoke connected with the trolley, the sides of which are directed upwardly.

TROLLEY ROPE PROTECTOR. H. M. Brooks, New Haven, Conn., 578,542. Filed Aug. 26, 1896.

A cup-shaped guard provided with a discharge spout at one side and placed adjacent to the trolley pole.

Switches, Cut-Outs, Etc.:—

ELECTRIC CUT-OUT. D. B. Kinch, Pittsburg, Pa., 578,643. Filed Sept. 26, 1896.

Consists of a socket plate adapted to receive in electrical contact a plug carrying one end of the loop connection, the plug being adapted to be turned in the socket and also to operate the switch-lever to break the main circuit and cause the current to pass through the loop.

CEILING CUT-OUT. H. T. Paiste, Philadelphia, Pa., 578,655. Filed May 8, 1895.

Comprises a binding post consisting of a single piece of sheet metal cut and bent so as to form a pair of jaws, an attaching lug projecting in the opposite direction from the jaws, and a connecting web bent so as to bring the jaws and attaching lug back to back.

TURN BUTTON FOR ELECTRICAL SWITCHES. J. S. Gibbs, Hartford, Conn., 578,695. Filed Jan. 6, 1897.

The key is utilized to retain the casing in position.

Telegraphs:—

TELEGRAPHIC REGISTER. C. E. Beach, Binghamton, N. Y., 578,386. Filed Oct. 21, 1895.

A device in which the printing attachment is impelled with greater force than usual with similar apparatus.

Telegraphs:—

CALL RINGER FOR TELEPHONES. J. A. Williams & S. Abbott, Cleveland, Ohio, 578,380. Filed April 10, 1896.

Comprises a tripolar permanent magnet and an electromagnet fixed between the legs of the magnet whereby the polarity in both of the magnets is in the same plane.

TELEPHONE TRANSMITTER. N. Lombard, Boston, Mass., 578.-520. Filed June 24, 1896.

Comprises a vibrating diaphragm consisting of a flexible plate adapted for support within a stationary holder and without mechanical attachment thereto, a loose pin centrally from the surface of the plate, and spring mechanism to maintain the surface of the plate convex toward the mouthpiece of the transmitter.

TELEPHONE. J. Weigel, Boston, Mass., 578,670. Filed July 14, 1896.

Comprises an inclosing casing provided with a diaphragm, a permanent magnet provided with a front pole piece, a spring interposed between the casing and the magnet and acting on the latter in a direction to move the pole piece away from the diaphragm, and means to limit the movement of the pole piece away from the diaphragm.

REPORTS OF COMPANIES

WESTERN UNION QUARTERLY REPORT.

The directors of the Western Union Telegraph Company have declared the regular quarterly dividend of 1¼ per cent., payable April 15. The quarterly report following shows that the earnings for the current quarter will be within $90,000 of the sum required for the dividend:

Surplus October 1, 1896		$7,795,907
Net revenues, quarter ended Dec. 31		1,545,454
Total		$9,341,361
Dividend January 15	$1,191,961	
Interest on bonded debt	223,358	
Sinking funds	20,000	
		$1,435,319
Surplus January 1		$7,906,041
Estimated net revenues quarter ending March 31		1,100,000
Total		$9,006,041
Interest on bonds	$223,358	
Sinking funds	20,000	
		$243,358
Balance		$8,762,682
Dividend 1¼ per cent		1,191,961
Surplus		$7,570,721

In 1896 the estimated net revenue for the quarter ending March 31 was $1,250,000, and in 1895 the actual net revenue for the same quarter was $1,163,781. The estimated surplus a year ago was $7,837,023.

THE STOCK MARKET

AND NOW CONGRESS.

There can be no question that the action of Congress now called to meet in extra session this week will have a great deal to do with the coming conditions of business. Not only is there the necessity to make the government of the country pay its way instead of running further into debt, but there is the associated necessity of making such changes in the tariff or excise as will yield that income. Hence, while such uncertainty exists in more or less degree till Congress has done its worst and gone home, the business of the country can hardly be expected to be very active or buoyant.

At the same time, better conditions do exist, and the stock market though generally dull has been remarkably strong and in spots quite optimistic. On the whole, financiers seem to have settled down to a belief in coming better times and to scepticism about any sudden amelioration.

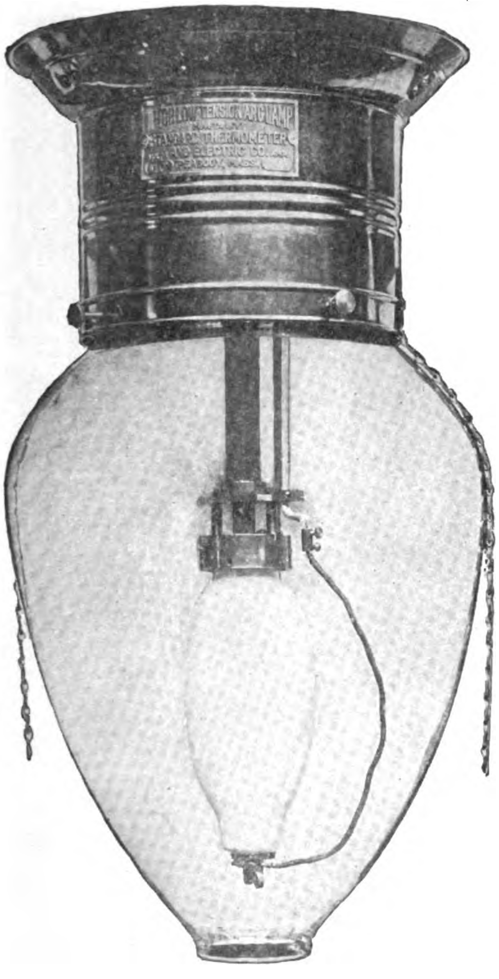
Western Union last week, on sales of 30,678 shares, went as high as 85¼ and closed at 84⅞. General Electric after a quiet week rested at 35, and American Bell Telephone remained as before at 224. Local securities in lighting, railway, etc., remain strong, but rather inactive.

TRADE NOTES & NOVELTIES

THE MIDGET ENCLOSED ARC LAMP.

ONE of the remarkable developments in electric lighting has been the recent enormous increase in the use of the enclosed arc lamp for interior illumination. Lamps intended for this purpose must of necessity be short, so as not to project too far down from the ceiling, and also call for the application of ornamental features not necessary with out-door lamps.

To satisfy both these conditions, the Standard Thermometer and Electric Company, of Peabody, Mass., have just brought out the Upton Midget enclosed arc lamp, which is illustrated in the accompanying engraving. The mechanism of this pretty lamp is extremely simple in construction. It consists of a single solenoid which operates a lever connected with a clutch. At the end of the lever is a dry-air dash-pot. The upper carbon is held in a brass tube by a suitable holder provided with brushes bearing against the interior of the tube. The clutch embraces the carbon at its point of entrance into the enclosed chamber of opal glass surrounding the arc, and is insulated to prevent the formation of an arc between carbon and clutch. A single movement of the lower carbon-holder unlocks it from the enclosure globe and permits the trimming of the lamp. The resistance coil, used for lamps on constant potential circuits, is mounted in the upper case above the solenoid.

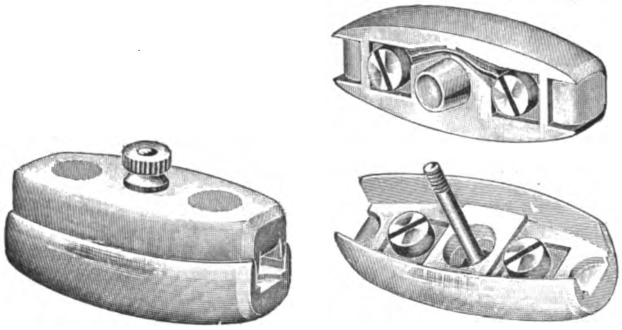


THE MIDGET ENCLOSED ARC LAMP.

The lamp, complete with the outer globe, is only 20 inches high, and without the globe, 18½ inches. A special form for show windows is made with concave or convex reflectors replacing the outer globe, to replace the ordinary group of incandescent lamps mounted in a mirror reflector.

BRYANT BUG CUT-OUT.

WE illustrate herewith a very neat and ingenious specialty recently placed on the market by the Bryant Electric Company, of Bridgeport, Conn. Figs. 1, 2 and 3 show their new bug cut-out in use and open for inspection. The construction is so readily understood from the cuts, which show the device full size, that no further elucidation is needed. Among the many advantages which obviously may be claimed for this specialty is the fact that it absolutely avoids short circuit. The fuse is placed in the cover instead of in the base, and it is not necessary to remove the connecting wires in order to replace a blown fuse. The device is small, compact, neat, well made and extremely reasonable in price.



FIGS 1, 2 AND 3.—BRYANT BUG CUT-OUT.

CENTRAL ELECTRIC CO.

The Central Electric Company advise us that the prospects for business are exceedingly promising. The inquiries for their numerous specialties are daily increasing, which gives evidence that their customers are providing for a lively trade.

It is quite evident that the Wagner direct connected alternating current ceiling fan motor, for which they are general Western agents, is bound to be a winner. It has many and unusually advantageous features which seem to appeal to prospective users with unusual force.

They are bringing out a new form of spark arrester made entirely of Russia iron, and adapted to be used in connection with most any form of arc lamp. Circulars fully describing this are being sent out and will be forwarded on application.

FIRE AT THE SPRAGUE ELECTRIC ELEVATOR FACTORY.

The new and costly shops of the Sprague Electric Elevator Company, at Watsessing, N. J., came very near total destruction on March 8 by fire. The main shops are nearly 400 feet by 100 feet, with an L nearly 200 feet long, and a separate power house about 100 feet long. There was nearly half a million dollars' worth of property endangered. The shop is a brick and steel gallery construction. The fire broke out about half-past two o'clock in the morning, in one of the main galleries, and spread very rapidly to the roof. The company put on three fire hose of its own, and would have got the flames under control very quickly but the water supply gave out. The fire was then fought from the overhead cranes with fire extinguishers, and by hose from the Bloomfield Fire Department. The flames spread along the monitor roof for a distance of about 160 feet to 200 feet. The damage by fire, smoke and water, the lower floor being flooded, is not very serious, and within forty-eight hours the shop was again in operation.

This company is busy installing elevators in the Queen's Insurance Building, the new Astor Hotel, and a number of other important buildings, but there will be very little delay, if any, in these equipments. The cause of the fire is as yet unknown. There has been a threatened strike in New York, and talk of its extending to the Watsessing Works, but it is not believed by the officers of the company that the fire was of incendiary origin, although it cannot be accounted for at present. The president of the company is Mr. Frank J. Sprague. Mr. John E. Searles is vice-president.

NEW APPARATUS OF THE WESTERN TELEPHONE CONSTRUCTION CO.

WE illustrate herewith several pieces of apparatus recently put on the market by the Western Telephone Construction Company, Chicago. Fig. 1 shows their 100-drop new improved type of switchboard. This board is remarkable for its compactness. It is of the same general style as the earlier boards manufactured by this company, but embodies many radical improvements in detail. The jacks and drops have been made larger and heavier, giving greater durability, and better electrical design. The circuit changer for switching the operator's telephone or generator into the circuit of two connected lines has been completely changed, the principal features of novelty being that the removal of eight screws allows the whole circuit changer to be slipped out of place and cleaned, without the unsoldering of a single connection. This cut shows the board "opened up." The upper part of the cabinet containing the jacks is so constructed as to swing outward, thus exposing at once the entire rear portion of the jacks and drops and their connection. The key table is shown turned upward, thus exposing the entire mechanism of the circuit changers to view.

Fig. 2 shows the power generator used for supplying the ringing current in telephone exchanges. The entire machine is mounted on a slate base, the pulley shaft being separate from the armature shaft, and connected thereto by a flexible rubber connection in such a manner as to prevent any undue jar or wear coming on the armature bearings themselves.

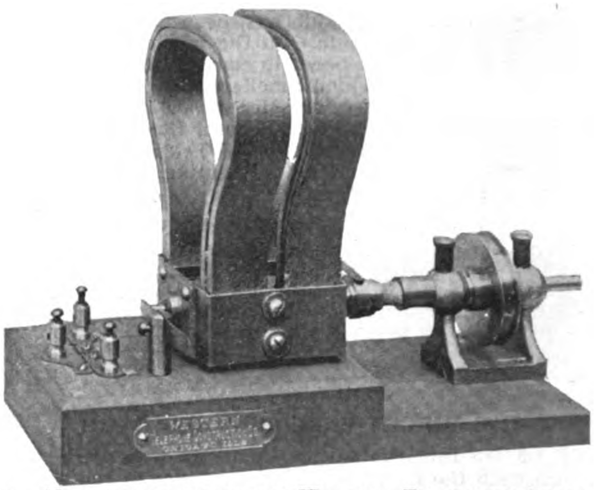


FIG 2.—NEW APPARATUS OF THE WESTERN TELEHONE CONSTRUCTION CO.

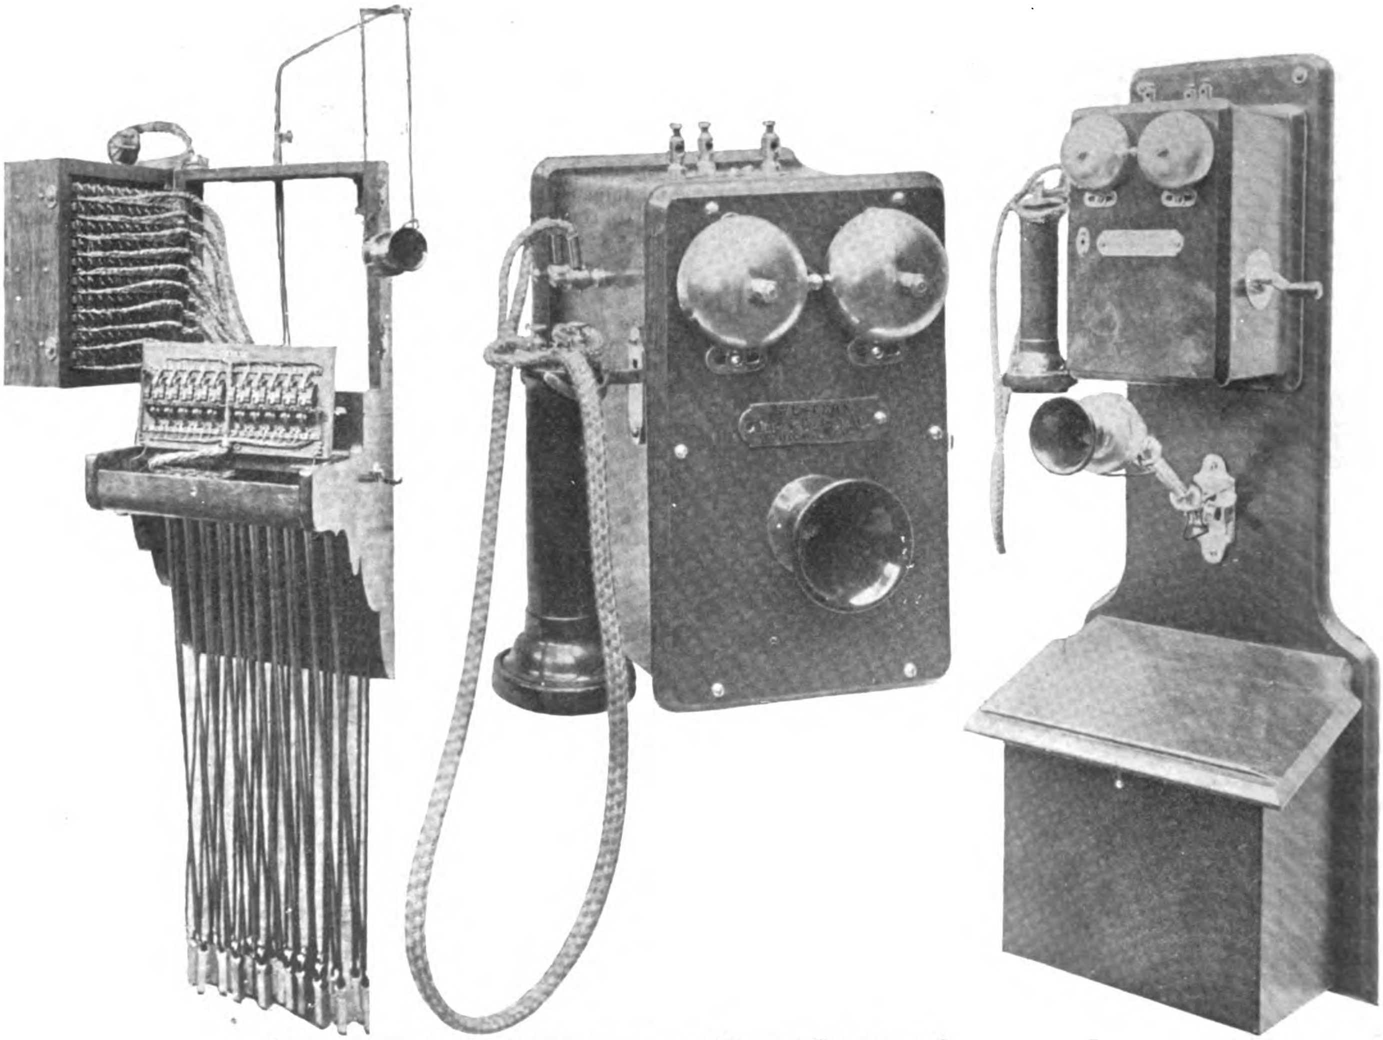

FIGS. 1, 3 AND 4.—NEW APPARATUS OF THE WESTERN TELEPHONE CONSTRUCTION CO.

Fig. 3 shows their Western Giant B telephone. This instrument is complete in itself, the box being no larger than the generator box on an ordinary telephone. With this type of instrument, the battery is placed in a closet, and the wires forming the local circuit run thereto from the transmitter. Fig. 4 shows their new rocker arm telephone. The transmitter is mounted upon a handsome nickel-plated arm with a knuckle joint at each end. So great is the latitude of motion allowed by this construction, that the transmitter may be completely inverted, thus forming a most efficient means of agitating the carbon granules. This instrument is provided with a powerful magneto-generator and call bell, and may be wound either for series or for multiple work. An automatic shunt-break is attached to the armature shaft, which effectively shunts the armature resistance out of the line at all times when the generator is not being used. The receiver is of the Western bi-polar type, and is extremely sensitive. Both of the latter instruments here illustrated are finished in either polished oak or walnut, and form a very handsome piece of furniture for any house or office.

THE CROSS OIL FILTER.

THIS filter has been manufactured by the Burt Manufacturing Co., of Akron, O., for nearly seven years and is in use by leading concerns throughout the world. They manufacture a complete line of from 3 to 120 gallons filtering capacity per day made out of iron, brass or nickel-plated copper.

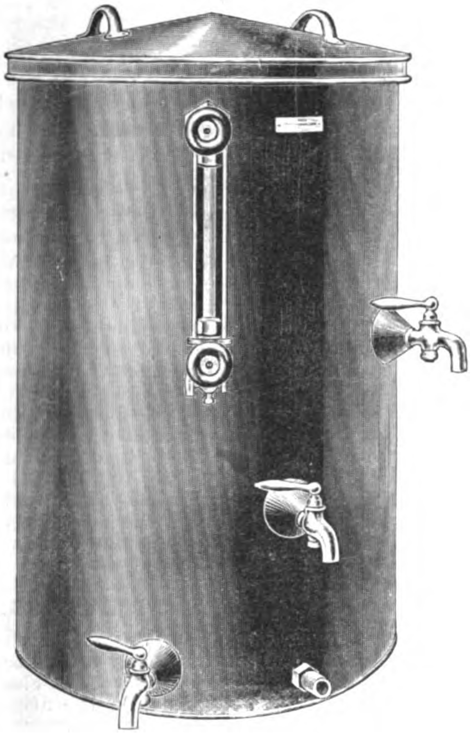

FIG. 1.—THE CROSS OIL FILTER AND PURIFIER.

The filter illustrated is made out of heavy galvanized iron, with polished brass fittings, gauge and cover, and nickel-plated rim. The bottom chamber E is filled with pure, warm water, which is heated by means of a steam pipe passing through the filter. Very little steam is required, and if the filter is kept in a warm place it will not be necessary to make steam connection at all.

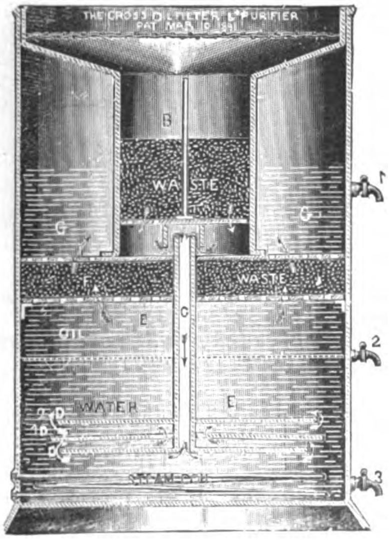

FIG. 2.—THE CROSS OIL FILTER AND PURIFIER.

The waste oil is poured in through top grating A. It then passes into chamber B, through the layer of waste, which collects all the heavier impurities, thence through the perforated bottom of the chamber B, down in the direction shown by the arrows into tube C, and from here into filter plate D, where the increased weight of the water has a tendency to keep the oil back in tube C. However the pressure of oil in chamber B forces it down and spreads it out over plate D, in a very thin film which constantly changes surface and grows thinner as it travels from the center to the circumference of plate D, thus exposing every particle of waste oil to the action of the water. It then flows upon plate D' and D", going through the same process in each case. When the oil leaves the filter plate D", it is in a finely divided state of separation and thoroughly mixed with water, which washes it out, and from which it separates by gravity all the remaining impurities which settle in chamber E, and can be removed through cock No. 3. From plate D" the oil again filters through the stratum of filtering material F, and from there it rises to chamber G, the reservoir containing the purified oil. It is then drawn off as required from cock No. 1.

"W-S" X-RAY PLANTS.

MR. JAMES G. BIDDLE, Drexel Building, Philadelphia, (sole agent for Messrs. Willyoung & Co.) has been very successful in securing a large number of orders for the now widely known "W-S" X-ray apparatus. The most expensive part of an X-ray outfit is the induction coil, and this very important piece, as made by Willyoung & Co., is remarkably effective and enduring. In addition to the adjustable condenser invented last year by Mr. Willyoung, a new improvement has been introduced in the "Ideal" automatic interruptor just placed on the market. It is so constructed that only about one-half the amount of current is required to energize a coil as the Apps or other forms of hammer head vibrators require. Furthermore, the "Ideal" interruptor does away almost entirely with sparking at the platinum contacts, and can be operated continuously without sticking. It can be connected to any direct current up to 110 volts, if the primary current is regulated by a suitable rheostat; but without necessity for rotary or mechanical break of any kind. The makers claim this to be the first automatic interruptor that can be safely connected to a 110-volt circuit in the manner indicated. Other parts of these equipments are equally meritorious as the induction coils, and interested parties should avail themselves of Mr. Biddle's offer to mail his new X-ray catalogue, No. 200, upon request. A few of the recent orders received by Mr. Biddle are from the Episcopal Hospital, Philadelphia; Jefferson Hospital, Philadelphia; German Hospital, Philadelphia; Girls' High School, Philadelphia; Emergency Hospital, Washington; West Penn Hospital, Pittsburg; Williamsport Hospital, Williamsport, Pa.; Catholic University, Washington; Hospital, Alton, Ill.; Hospital, Boise City, Idaho; College of Medicine, Cincinnati; Hospital, New London, Conn.; Hospital, Lancaster, Pa., etc.

AMERICAN MANUFACTURERS' AND EXPORTERS' EXCURSION TO SCANDINAVIA.—THE STOCKHOLM EXHIBITION.

Arrangements have been made for an excursion of American manufacturers and exporters to Denmark and Sweden, including the Stockholm Exhibition, to start from New York in May or June this year. The object of this excursion is for American manufacturers and exporters to investigate for themselves the facilities of opening trade with the northern part of Europe through the free port of Copenhagen. A stop of ten days will be made in Copenhagen, thence the excursion will proceed to the industrial exhibition in Stockholm, Sweden. Another stop of ten days will be made there, which will enable the participants to examine the industries of the Scandinavian countries, and thereby judge for themselves to what extent American products could be introduced in these countries.

The whole trip can be made in two months, and the ordinary expenses will not exceed $210, including first cabin on steamer from New York to Copenhagen and return (Thingvalla Line); first-class railroad to Stockholm and back; ten days' stay at first-class hotel (rooms only), both in Copenhagen and Stockholm.

The excursion will be led in person by Mr. George Kirkegaard, 28 State street, New York, who will gladly supply further information and illustrated pamphlet relating to the free port of Copenhagen.

The northern countries of Europe import considerable quantities of electrical apparatus and are well worthy the attention of Americal manufacturers. Mr. Kirkegaard is personally known to us and has already received a number of acceptances.

GRAPHITE FOR RESISTANCE PURPOSES.

For some years the Joseph Dixon Crucible Company, Jersey City, N. J., have been supplying graphite resistance devices in quite a large way to telephone companies, electric light companies, and electricians generally. The resistances have been so satisfactory and demand so promising that they have now added to that department of their works, dynamo and all necessary apparatus for testing purposes and are prepared to furnish graphite resistances in round or square rods, tuoes, spirals and other devices as wanted, of one ohm resistance of one million ohms resistance, as required.

THE FRECK TUBE CUTTER.

A FREQUENT operation in machine and repair shops is the cutting of tubes and pipes, yet much time is generally consumed in this work by doing it by hand or on machines ill adapted for it. To meet the special demand for a tube cutter, the Wm. Freck Company, of Chicago, Ill., have brought out the handy little tool shown in the accompanying engraving, Fig. 1. This machine will cut tubing from 2 inches diameter down, and any length from $^1/_{16}$ inch up. The tubing is laid down on the rollers, and resting on the V-shaped arm on gauge-rod, the cutter-wheel is brought down on the tubing by means of the lever, assuring a straight, clean cut with the greatest rapidity and ease.

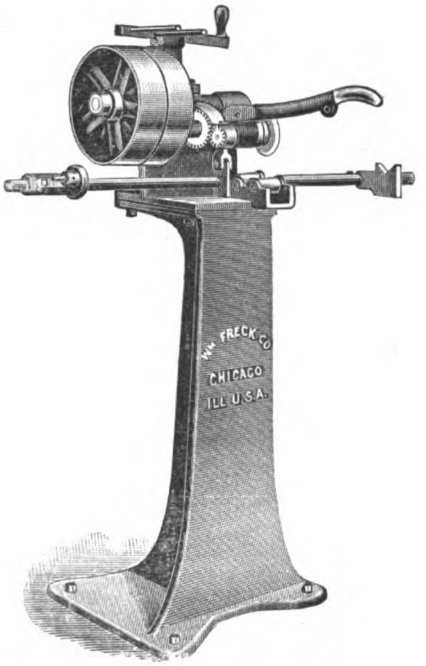

FIG. 1.—THE FRECK TUBE CUTTER.

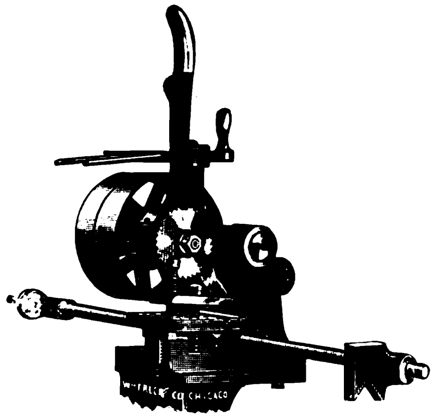

FIG. 2.—THE FRECK TUBE CUTTER WITH SAW ATTACHMENT.

The arm which carries the cutter-wheel is accurately fitted into the head and swings on the main shaft. This shaft is of steel, and forms a pinion at a distance where it rests against the head, transmitting power to the steel pinion, which carries the cutter-wheel by means of an intermediate spur-gear. A hand-screw with check-nut is provided so that cutter can be stopped at any required depth. The lever which raises and lowers the cutting-wheel is so constructed that it requires only a slight pressure when cutting, and when thrown back in an upright position, locks itself automatically, no springs being used.

The Freck Company also make a sawing and slotting attachment to fit this machine, to run a 4-inch circular saw for sawing brass, iron and steel bars and tubing, and for slotting any machine parts, screws, etc, Fig. 2. When sawing solid bars, a small weight hung in the hole on lever will make the saw feed automatically.

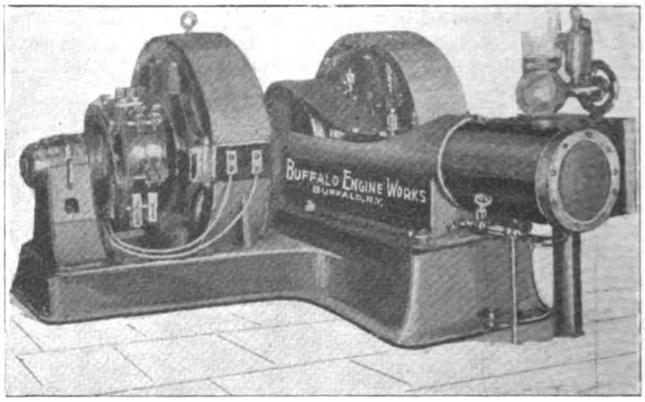
The machine is 50 inches high over all, takes 16x16 inches floor space, weighs 210 pounds.

ELECTRIC POWER IN MEXICO.

The Pelton Water Wheel Company, of San Francisco, Cal., have recently sent a power plant to Mexico, which has some features of unusual interest. The plant embraced two 67-in. three-nozzle Pelton wheels, having a capacity of 700 horse-power, running under a head of 100 feet. The station operates a jute factory located at Barrio-Nuevo, in the State of Orizaba, some 60 miles inland from the port of Vera Cruz. These wheels are connected to four electric generators and the power transmitted to the factory 1¼ miles distant. No line or counter shafts are used—every machine in the factory being run by a separate motor, these varying from 1 to 20 horse-power as required. Pelton differential governors are attached to the wheels, which afford an absolutely uniform speed under all variations of load. The most sanguine expectations of its projectors have been realized in the economical and reliable service afforded. When it is considered that some 30 per cent. of the power in a plant of this character is usually absorbed by shafting and belts, and that constant expense is necessary in maintenance, the advantages of such a direct connection where electricity is the means of power are most apparent.

THE BUFFALO ENGINE AND DYNAMO.

THE Buffalo Engine Works, of Buffalo, N. Y., whose steam engines are well known, have recently brought out an automatic high speed engine, specially adapted for electric lighting. This engine, which is illustrated in the accompanying engraving, combines the pleasing outline and the massiveness and solidity of structure so well known and recognized on their other machines. Simplicity of construction and large wearing surfaces, together with the best material and workmanship, add increased life to the machine.



THE BUFFALO ENGINE WORKS HIGH SPEED AUTOMATIC ENGINE AND DIRECT CONNECTED DYNAMO.

The construction of the governor is such that there is the minimum variation from light to heavy load. Perfect lubrication of the moving parts is secured by the most approved oilers and lubricators, while the waste of oil and its attendant discomforts are prevented by suitable guards and oil catchers. All direct-coupled engines are built on a heavy cast iron sub-base in line with the generator, thereby securing the permanent alignment of both engine and generator, while securing the utmost rigidity and the most pleasing design.

The Buffalo Engine Works have, until recently, confined themselves to building steam engines and refrigerating machines, but have quite recently taken up electrical work, doing a general construction and supply business, as well as manufacturing a full line of dynamos and motors and are prepared to install direct-connected dynamos.

The armatures of the two-pole machines are of the drum pattern; all others are ring cores. The latter are built up of discs about ½ mm. thick of iron showing least hysteresis, stamped out, and then annealed before building up. The cores are slotted to receive the conductors, and wound over all with one layer of soft square iron wire, thereby reducing heat loss in conductors to a minimum. The field cores are of wrought iron. The fact of the armature being slotted and wound over with iron wire after conductors are in place permits the armature core to run very close to the pole blocks, thereby reducing the air gap, consequently necessitating much fewer ampere turns in the field coil, and hence effecting a saving in energy in that direction.

The bearings are self-aligning, self-oiling and are so constructed as to be able to compensate for wear, and at the same time hold the armature central. It is absolutely impossible for any oil to creep or leak from the bearings, as they are so constructed that the oil must flow back to the well again. The arrangement is entirely new from anything now on the market.

Brush holders are also of an entirely new design, permitting of a very wide range of tension. The machines throughout embody all of the most recent improvements, including carbon brushes.

The Buffalo machines are built in sizes of from one to twelve kilowatts, in either two or four pole, and for sixteen and upwards six poles. Our engraving shows one of the machines direct connected to a Buffalo high-speed automatic engine.

It is the purpose of the Buffalo Engine Works to do a general electrical construction supply and manufacturing business. The proprietors are R. F. Strum, A. B. Hartung, C. J. Zacher, with Fred J. Cross, E. E., as manager. Mr. Cross has had a wide experience in machine designing and is considered to be one of the best designers of the day. All machines of his design are giving the utmost satisfaction. He has eleven patents protecting his designs and appurtenances.

ADVERTISERS' HINTS

CARLISLE & FINCH, 830 West Sixth street, Cincinnati, Ohio, are selling complete electric railways at $3.00. This includes car, track and bichromate battery.

THE GOODYEAR VULCANITE COMPANY, 353 Broadway, New York, manufacture hard rubber rod, sheet and tubing and make a specialty of hard rubber goods for electrical and mechanical purposes.

A. L. BOGART, 22 Union Square, New York, is advertising his No. 18 multiple porcelain burner, which, he states, is the only absolutely safe burner for electric gas lighting in theaters, churches, etc. Each burner is provided with an unbreakable nickel-plated steel tip, making their operation very reliable.

WARD LEONARD ELECTRIC COMPANY, Hoboken, N. J., direct attention to the marked advantages of their automatic circuit breakers, which have just been introduced.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., remind central station managers of the Holly system for the heating of all kinds of buildings by exhaust steam, enabling them thus to utilize what is otherwise a waste product.

RILEY BROS., 16 Beekman street, New York, carry a full line of magic lanterns and accessories. They manufacture the Riley kineoptoscope for the projection of living pictures, by which every movement of actual life is depicted on a screen.

THE PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., manufacture and deal in telephone supplies, including batteries, zincs, building posts, porcelain insulators, test connectors, carbon dust and salammoniac.

THE BRYANT ELECTRIC COMPANY, Bridgeport and Chicago, are supplying the Bryant "bug,' which has one nut only. The fuse is placed in the cap and it is not necessary to remove connecting wires to replace it.

THE WESTERN TELEPONE CONSTRUCTION COMPANY, Chicago, say their telephones speak for themselves.

K. McLENNAN & CO., 206 Dearborn street, Chicago, offer some more reports on the use of Gale's commutator compound, of which they are the sole manufacturers.

THE PHŒNIX INTERIOR TELEPHONE COMPANY, 93 Washington street, New York, offer to replace, free of charge, any transmitter that loses its adjustment, packs, or deteriorates in any way within two years from date of purchase.

THE MISSOURI TELEPHONE MANUFACTURING COMPANY, St. Louis, make a sixty-day offer on their No. 98 microphone. Full nickel finish and are good for one mile or one thousand.

THE ILLINOIS TELEPHONE SUPPLY COMPANY, 356 Dearborn street, Chicago, submit a list of prices on telephone outfits and supplies.

F. M. LOCKE, Victor, N. Y., is furnishing insulators for any current up to 50,000 volts.

NEW YORK NOTES.

THE STANDARD AIR BRAKE COMPANY, 100 Broadway, report an excellent inquiry for their brakes and a growing conviction among progressive managers that only power brakes are permissible with the modern heavy car and travel in crowded streets. Their list of sales grows steadily, and not the least striking part of it is the number of foreign orders with which it is decorated.

THE BULLOCK ELECTRIC COMPANY are already settled in their new quarters on the sixteenth—or is it the sixtieth?—floor of the new St. Paul Building, whence they look down on the busy world beneath, and derive new inspiration every minute from the activity manifest in every direction. The offices are roomy, cosy and convenient, and are hung with many pictures illustrative of Bullock motor installations and the work such motors do. Mr. R. T. Lozier and his brother have got up also some excellent stationery for the company, which is in quiet good taste, yet impressive and characteristic. They report business as good, and the outlook never better for motor equipments.

THE BROOKLYN UNION GAS COMPANY and the Brooklyn Edison Company are said to be investigating and locating electrolytic troubles caused by trolley leakage, with the object of bringing suit to recover damages.

McLEOD, WARD & CO., 27 Thames street, report a satisfactory business in all their lines, especially their Kinsman desk lamps and also their spark arresters.

A. & R. BOILERS.—The Abendroth & Root Manufacturing Company, 28 Cliff street, New York City, has through its St. Louis office secured an order from the Alexian Brothers for two Root improved water tube boilers, 150 horse-power each, to be installed in the new hospital in Chicago. The company has also secured the Schwarzchild & Sulzberger order for water tube boilers in the face of a close competition, for their packing plant in Kansas City. This order calls for 1,000 horse-power.

HENRY R. WORTHINGTON, manufacturers of steam and electric pumping machinery, have recently received a contract from the Newport News Ship Building and Dry Dock Company, amounting to $100,000, for pumps for the United States battleships Kearsarge, Kentucky, and Illinois. They are also building the pumps and pumping machinery for the United States battleship Alabama, now being constructed by the Wm. Cramp & Sons Ship and Engine Building Company. The contract for the pumps for this vessel amounts to $33,000. The company have just completed and delivered the hydraulic machinery for operating the turrets on the United States battleship Iowa. They have more recently received a contract amounting to $15,000, covering the pumps required for the armored cruiser being built by the Wm. Cramp & Sons Ship and Engine Building Company, for the Japanese Government. The Yoshi-No, another Japanese cruiser, is already fitted out with a full complement of Worthington pumps. The fact that with few exceptions all British and other foreign war vessels are equipped with these machines simply adds another testimonial to the high efficiency of the Worthington duplex steam pump.

THE NEW YORK TELEPHONE COMPANY will, it is expected, put a new building up at Gold street, near Fulton, where it now has extensive quarters.

THE GOVERNMENT PRINTING OFFICE in Washington has a fine electric power plant, described in a recent official bulletin, noted in our columns lately. It deserves mention that the motors are of Crocker-Wheeler Co.'s make.

HUDSON RIVER TELEPHONE COMPANY.—The report of the president shows that the receipts during 1896 were $299,999.59; expenses, $204,347.66, leaving as net revenue the sum of $95,651.93.

MONTREAL, CAN.—The contract for the electrical equipment of the Montreal Park and Island Railway Company's suburban lines has been awarded to Ahearn & Soper, Ottawa, Can. Westinghouse No. 38 B and No. 12 A motors will be used throughout.

NEW ENGLAND NOTES

THEODORE H. COLVIN, of Providence, R. I., has commenced work on his new foundry building. This building will be 102 feet wide and 180 feet long, and will be a complete and modern foundry building in every respect. The central portion, 50 feet wide, will be served with a 20-ton traveling crane, and at distances of about 25 feet in the length of the building will be placed 5-ton jib cranes swinging from the central portion of the building over the moulding floors in the wings, which extend along both sides of the building and are 25 feet wide. The entire frame work of this building will be steel. The roof covering is to be slate. The steel work is being furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

THE WASHBURN & MOEN MANUFACTURING COMPANY have just sold to the New York, New Haven and Hartford Railroad Company, for its new electrical equipment, at Berlin, Conn., a large number of their "Crown" rail bonds. These bonds are stranded, are above 300,000 c. m. capacity, and are to be applied underneath the rail, two bonds to each joint. The "Crown" bond is the newest thing in the market, being made in different shapes, so as to meet all conditions of rail bonding, and immediately engages the attention of every railroad man who sees it.

MR. CHARLES I. HILLS, of the Perkins Electric Switch and Manufacturing Company, has started on an extensive trip West, in the interests of his company. Mr. Hills will probably be gone from New York about six weeks, and will reach the Pacific coast before his return. Mr. Hills' numerous friends in the West will undoubtedly be glad to see him, and get the latest metropolitan news.

MR. J. H. EDWARDS.—The business of the Berlin Iron Bridge Company, of East Berlin, Conn., has increased to such an extent that Mr. Chas. M. Jarvis, who has been chief engineer of the company since its organization, has been obliged to resign to others the engineering department and give his entire time and attention to the business management of the corporation. The directors have therefore appointed to the position of chief engineer, Mr. James H. Edwards, a graduate of Cornell University, who has been with the bridge company a number of years, during which time he has been the chief assistant to Mr. Jarvis. Mr. Edwards is by education and experience well qualified for the new and important position to which he has been elected.

WESTERN NOTES

MR. O. C. LITTLE, of Menasha, Wis., associated with Mr. M. M. Schoetz, is the manufacturer of a pulley coating for which he has received several testimonials from central stations as well as many mills, factories, etc. Sample sheets of this saver of oil, fuel and belts will be sent on application.

THE ELECTRIC APPLIANCE COMPANY makes it a practice to keep its customers posted on any changes in market prices, and to this end it is the custom to publish at frequent intervals a bulletin of prices, on staple goods. Such a bulletin has just been issued, giving present market prices and a number of the Electric Appliance Company's well-known specialties. It contains valuable information to every purchaser of electrical supplies, and will be sent to the trade on application.

THE PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., say there was never a time in the history of their factory when they had so great a demand for the Laclede batteries as they are having at the present time.

MR. F. A. ROSS has been appointed general manager of the Stromberg-Carlson Manufacturing Company, of Chicago, in place of Mr. M. C. Wheaton, who recently resigned.

THE WESTERN ELECTRIC COMPANY have issued a pamphlet on fan motors, which is of a very descriptive and interesting nature.

THE METROPOLITAN ELECTRIC COMPANY of Chicago are agents for the Perkins incandescent lamps, and switches, and report a fine trade in this justly popular line of electrical goods.

THE CENTRAL ELECTRIC COMPANY reports that one of the good signs of the times is found in the fact of increasing sales of all kinds of construction and line material. This would indicate a strong probability of lively business when the season opens up.

THE ACME ELECTRIC MFG. CO. has been formed at San Francisco, Ca., by W. T. G. Schenck, L. St. D. Boylance, S. B. Peterson, F. J. Dyer, and M. S. Schenck. The capital stock is $50,000, of which $20 has already been subscribed.

MR. JOHN T. McROY, 915 Chamber of Commerce Building, Chicago, has issued for March a neat blotter advertising his terra-cotta conduit, and encloses with it a pretty card which gives some good points on the same material for subway uses.

FOREIGN NOTES.

THE COX LABORATORY.—Newspapers are to hand with reports of the unfortunate fire at the Cox Laboratory, St. Albans, England, where the Cox thermopiles were being made. The destruction appears to have been pretty complete, not only of the laboratory, but of some 600 of the generators awaiting shipment. There had been several exhibitions of the apparatus during the week, to the press and others, and it is possible that the circuits had been worked beyond their safety limit in showing the use of the current for even large work in light and power. The loss reaches probably $100,000. Steps for resumption of work were taken immediately. The English "Railway World," of March, has an interesting article on Mr. Cox's invention.

THE LA CAPITAL CO., of Buenos Ayres, Argentine Republic, South America, have let to parties in the United States contracts for the materials for a power station, the necessary equipment for the power in the station, and the roadbed and cars. The Berlin Iron Bridge Company, of East Berlin, Conn., have the contract for furnishing the skeleton steel work of the building and the roofs. The roof over the engine and dynamo room will be covered with corrugated iron lined with the Berlin Company's fireproof anti-condensation roof lining.

The Electrical Engineer.

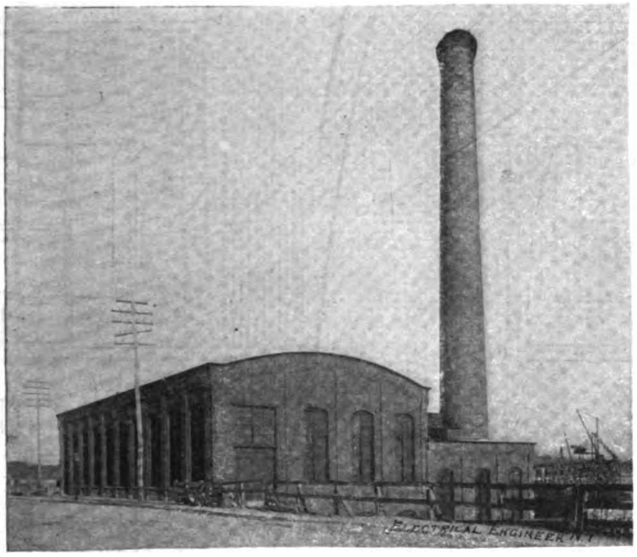
Vol. XXIII. MARCH 24, 1897. No. 464.

ELECTRIC TRANSPORTATION

THE DORCHESTER POWER STATION OF THE WEST END ST. RY. CO., BOSTON, MASS.

By H. W. WELLER.

EARLY last year the directors of the West End Street Railway Company foresaw that the rapidly increasing traffic of the Dorchester, Neponsett, Ashmont and Milton lines necessitated a more centrally located plant, where sufficient power could be economically provided, for the present and future needs of this portion of their territory, now being built over and settled at an astonishing rate.



General View of Dorchester Power Station, West End Street Railway Co., Boston.

LOCATION OF THE STATION.

After careful consideration a suitable plot of ground was purchased, located at Commercial Point, on Dorchester Bay, offering every facility for procuring ample water for condensation and for obtaining coal at tidewater. The work of preparing all the necessary plans and specifications was quickly put in hand, and, before spring opened up, the contracts were let, and early in April last the work was commenced and pushed rapidly to completion.

The plot has a frontage on Freeport street of about 300 feet, and the building is about 125 feet long, the engine room being next to the street, with the boiler room adjoining and in the rear. The stack is located behind the boiler room.

THE BUILDINGS.

The buildings are of the best selected hard-burned brick, with freestone trimmings, the foundations being of concrete and stone. The engine room floor being on a level with Freeport street, the front wall of the basement is built of granite, as a retaining wall, and is protected from the damp by a damp proof course of tar and pitch.

The roof is carried on arched iron trusses supplied by the Boston Bridge Company, and is of special fireproof construction, being a series of arches springing from truss to truss, the arches being of two layers of flat fireproof tiles laid in cement. This special roof construction was designed by Mr. Baker, and carried out under his instructions by Messrs. Guastavino, of Boston.

COAL-HANDLING APPARATUS.

Projecting out into the bay is the coal dock and hoisting and conveying machinery, designed and installed by the engineers of the West End Company. The coal is brought in barges to the dock, and hoisted by a 40 horse power duplex vertical engine to the top of the trestlework, where it is dumped into automatic self-dumping cars. The cars, on arriving at the inner end of the trestle, dump their load and return to the hoist. The cars and special rails were furnished by the C. W. Hunt Company, of New York.

The storage capacity of the dock is upward of 5,000 tons, which allows an ample store of coal being kept in case of continued frost in the harbor or any other unforeseen interruption of the supply. As the coal is brought into the fireroom it is weighed and entered in the daily log.

THE BOILER ROOM.

The boiler room is 122 feet in length by 51 feet in depth and of ample height. It is substantially built of selected hard-burned red brick, with granite water tables and freestone cornices, sills and trimmings. In it are installed two batteries of two 500 horse power boilers each, of the well-known Babcock & Wilcox type, making a total capacity of 2,000 horse power, and space has been left for the installation of another battery of 1,000 horse power in the future.

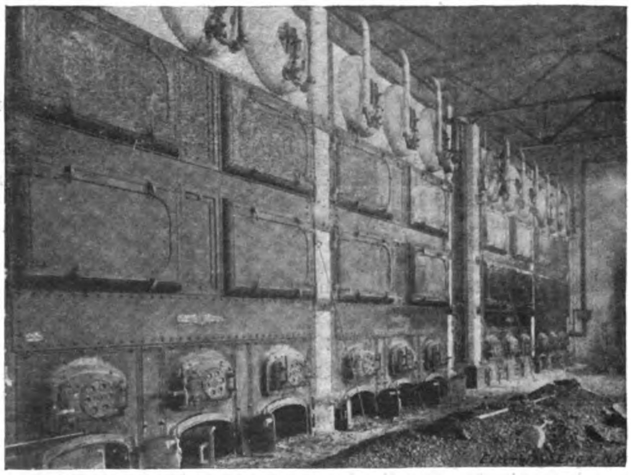
As shown in the accompanying illustration, each boiler has three 42-inch water drums, projecting through the front of the setting, each drum being protected by a 5-inch Ashton pop safety valve, set to blow at a pressure of 175 pounds. All the feed piping and connections are of extra heavy brass, and the water columns are of the Reliance pattern, fitted with high and low water alarms.

The feed water is taken into the front of each drum, with a duplicate system connected into the rear of each drum. To facilitate the removal of tubes, when necessary, large doors are located in the wall of the building, opposite the fronts of the boilers. These doors are hung vertically on chains and balanced with counterweights.

The smoke flue from each boiler is connected into one main flue, which carries the gases into a Green economizer of 1,000 horse power capacity, located in the boiler room opposite the stack and connected with it by a brick flue 12 feet square. A by-pass flue, with two dampers, is also provided for use when the economizer is shut down at any time. There is also a damper at each end of the economizer.

A novel feature in connection with this part of the plant is the provision of sufficient room above the economizer for removing defective tubes, and for proper inspection and cleaning. The top of the economizer is reached by three flights of iron stairway. The scrapers for keeping the tubes of the economizer clean are operated by an electric motor run from the trolley circuit. The scrapers are usually operated for about one hour each day.

A flue damper is also provided in the setting of each boiler. The draft is automatically controlled by the main damper in the stack, operated by a Spencer damper regulator. An indicator on the wall of the engine room shows the position of this damper at all times for the engineer's guidance. An underground tunnel, protected with iron gratings, passes underneath and across each boiler. All the ashes drop through these gratings into the tunnel, and are carried by the discharge from



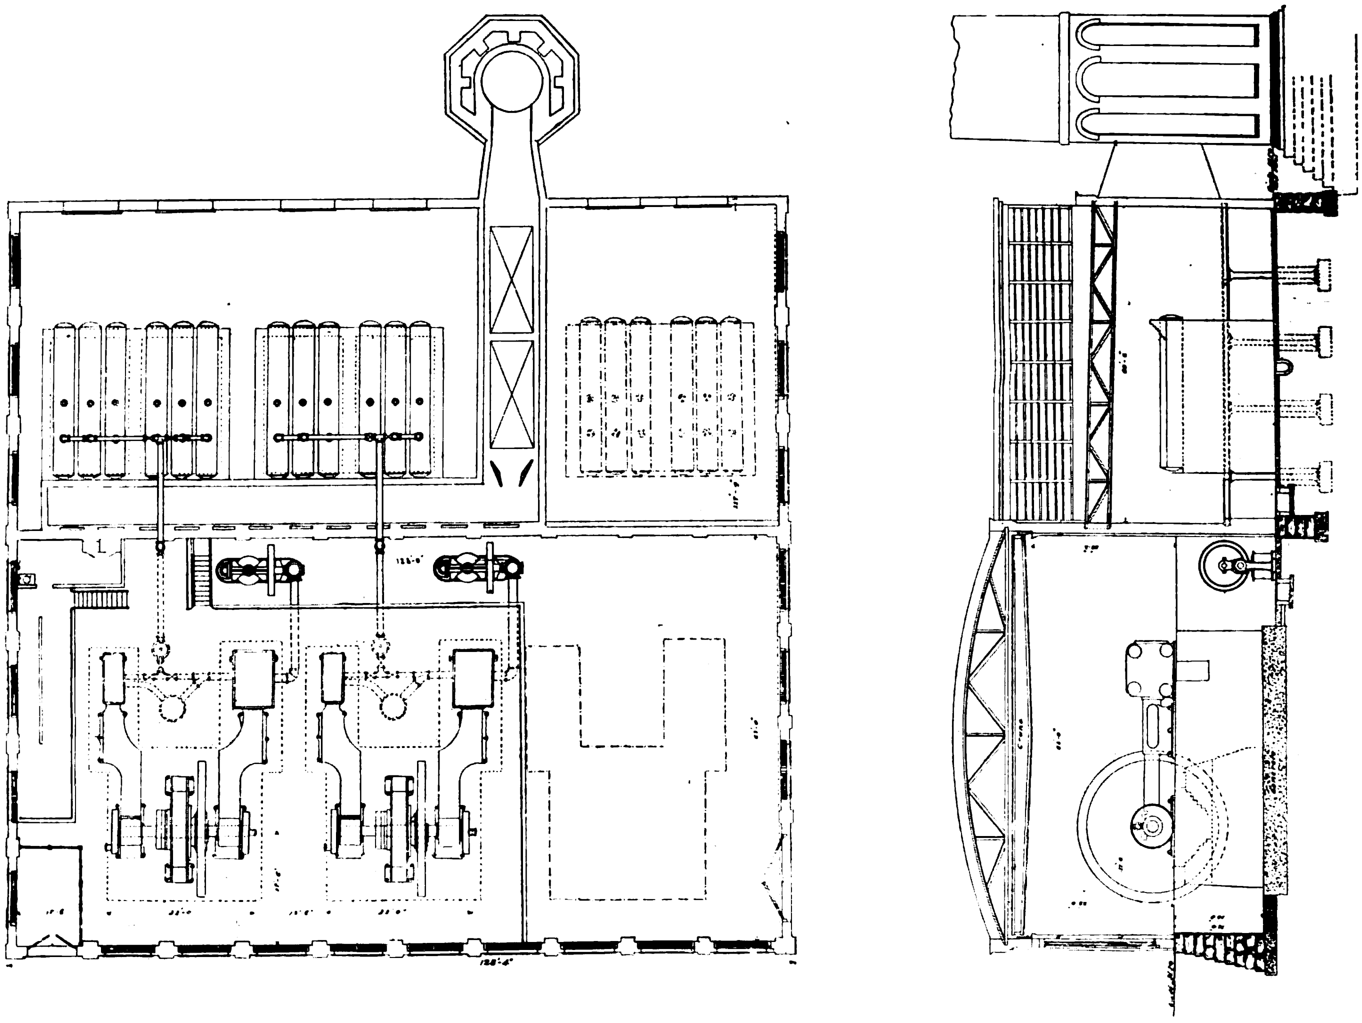
Babcock & Wilcox Boiler Room, Dorchester Power Station.

the condensers, which passes through the tunnel, out onto mud flats owned by the railway company, and which will ultimately be reclaimed and utilized.

The blow-off piping is carried in the rear of the boilers in a concrete trench, covered with floor plates of cast iron. The boiler room floor is of cement concrete, which forms a smooth and durable surface.

THE STACK.

The stack is of selected hard-burned red brick, with a 10-inch fire brick lining, for a height of 50 feet. It is carried to a height of 200 feet, and is octagonal in shape for the first 24 feet, with moulded corner brick, and a granite plinth of about one foot in thickness. From this point it is circular, and of an outside diameter of 20 feet, tapering toward the top, where it is 15 feet in diameter, and is finished off with a cornice and capped. The inside diameter is 10 feet. The stack is protected from lightning by four rods, one-half inch in thickness and projecting 6 feet above the cap. These rods are of copper and tipped with platinum.



Elevation and Plan, Dorchester Railway Power Plant, Boston, Mass.

The foundations for the stack are of cement concrete and capped with granite. The stack is of ample size to handle double the present capacity of the plant.

THE ENGINE ROOM.

The engine room is 122 feet in length by 63 feet in width inside, built of selected hard-burned brick, with freestone trimmings and sills. It is exceedingly well lighted, having 19 large sash windows on three sides, and on the fourth side, where it adjoins the boiler room, 10 smaller windows are provided, above the level of the boiler room roof, for ventilation. These swing on centers, and are controlled by hand-wheels from the engine room floor. Large double doors are provided on the front and on the end of the room.

The engine room floor is laid with 4-inch spruce planking on iron girders, and finished off with narrow strips of hard maple, polished and oiled. An open pit, guarded by brass railings, is left in the floor, as shown in the plan, over the pumps and condensers, to permit of their being seen at all times from the engine room.

In the engine room is installed a traveling crane of seven tons capacity, the tracks for which are iron girders built into the side walls of the building. The crane was manufactured and installed by the Boston Bridge Company, of Boston.

THE ENGINES.

There are two horizontal, cross-compound, direct-connected engines, built by the Rice & Sargent Engine Company, of Providence, R. I. The engines are duplicates, having cylinders 26-inch and 50-inch x 60-inch stroke. They run at 80 revolutions, and steam is supplied at 120 to 175 pounds, according to the time of the year and load. The centers of the high-pressure and low-pressure cylinders are 22 feet apart. The diameter of the shaft is 24 inches, reduced to 22 inches at the bearings, which are 3 feet 2 inches long.

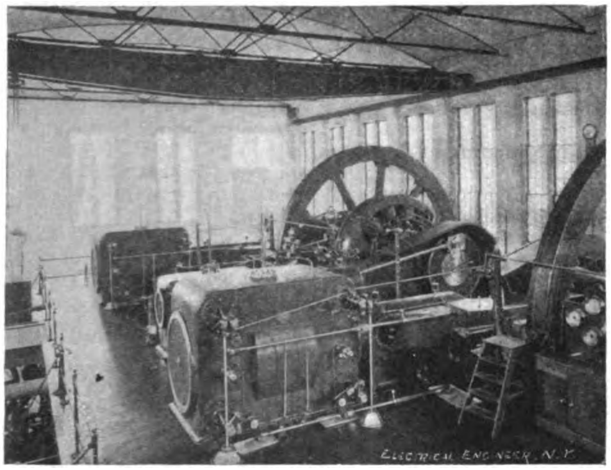
The fly-wheels weigh 120,000 pounds each, and were specially designed by the makers for safety. The rim is of forged steel, made in five segments, with interlocking joints, keyed together. There are ten arms, made of hollow steel castings. The hub of the wheel was forced on the shaft with a pressure of 350 tons, and has a flange which bolts to the armature. The engines are of massive design, and with extra large bearings throughout. The valve gear is the regular Rice & Sargent releasing gear. There is a re-heater receiver between the cylinders, and the piping is arranged so that either cylinder may be run alone, condensing or non-condensing. All piping is below the floor.

The engine and pipe connections are covered with magnesia composition, supplied by Messrs. Nightingale & Childs, of Boston. The foundations for the engines are laid up in hard red brick in cement, and finished off with granite capstones of about 12 inches in thickness. All valves are of Walworth, heavy duty, flange pattern, with outside screw and yoke and by-pass, and were specially designed and manufactured by the Walworth Manufacturing Company, of Boston. All main valves are controlled from the engine room floor. Iron stairways connect the engine room with the basement.

FEEDWATER HEATERS, PUMPS, Etc.

The basement floor is of cement concrete 15 feet below the level of the engine room floor, and is carried through on the same level as the floor of the boiler room and connected with the latter by two doors, one at either end. In the basement are located the condensers, feed pumps, heaters, etc.

The feed pumps consist of one Davis improved power pump, built by the Davis Company, of New Haven, Conn. It has four plungers, 6-inch diameter by 6-inch stroke, and is operated by a 15-horse power Edison bipolar 500-volt motor. There is also a duplex steam pump 6x8x12 inches of the Deane Pump Company's make. An additional method of feeding the boilers is provided for by the installation of two 3-inch injectors manufactured by Messrs. William Sellers & Co., of Philadelphia, Pa.; two feed-water heaters of a capacity of 600 horse power, manufactured by the Harrisburg Heater Company, of Harrisburg, Pa., are connected with the exhaust piping, and raise the temperature of the feed-water to about 128 degs. Fahr. before passing through the economizer, the feed-water finally entering the boilers at a temperature of from 200 to 220 degs. Fahr.



Dorchester Station, G. E. Generators and Rice & Sargent Engines.

THE PIPING.

The steam piping is laid out in duplicate, and specially designed and constructed for high-pressure work. It is extra heavy, with steel flanges, and all flanges are grooved and tongued and connected together with corrugated copper gaskets. The piping was designed by Mr. C. F. Baker, and erected by the engineers of the West End Company, under his supervision. All the fittings are of cast steel, made by the Penn Steel Casting Company, of Chester, Pa., and all the ells are of long turn pattern.

The main steam pipe is 10 inches in diameter, and the connections from each boiler are 8 inches in diameter. A 10-inch Stratton separator is installed between the main steam pipe and each engine to remove the entrained moisture from the steam.

The discharge from the separators is piped to the reheating coil in the receiver between the engine cylinders, and is then passed directly into the suction of the feed pump and thereby returned to the boilers. An automatic relief valve is provided in the line of the exhaust piping, to allow a free exhaust into the atmosphere in case of trouble with the air pumps or condensers.

The steam and feed piping is covered with the magneso asbestos sectional covering supplied by the H. W. Johns Company, of Boston and New York, and is neatly finished off with polished brass bands.

The engines are supplied with a system of oil drips and catch-basins, and the oil is carried by a gravity system of piping to the filter and tank, which has a capacity of 40 barrels. From this tank the oil is pumped up and again delivered by gravity to the different parts of the engines.

THE CONDENSERS.

The condensers were supplied by the Conover Manufacturing Company, of New York, and are of the vertical single acting independent, jet type, with air pumps 34 inches diameter by 14 inches stroke.

The engine operating the air pump is their regular trunk pattern, compound condensing, and is fitted with special Corliss valve gear. Steam is admitted at one end only for a full revolution, and eight to twelve expansions of steam are effected, according to the steam pressure. As the load on the condenser is practically constant, the cut-off is adjustable by hand, and the throttle governor controls the speed by furnishing the initial steam pressure in the cylinder, called for by the point of cut-off.

A special clutch arrangement is used to allow the valve gear to be operated by hand in starting. The oil is distributed by means of stationary cups and wipers.

THE GENERATORS.

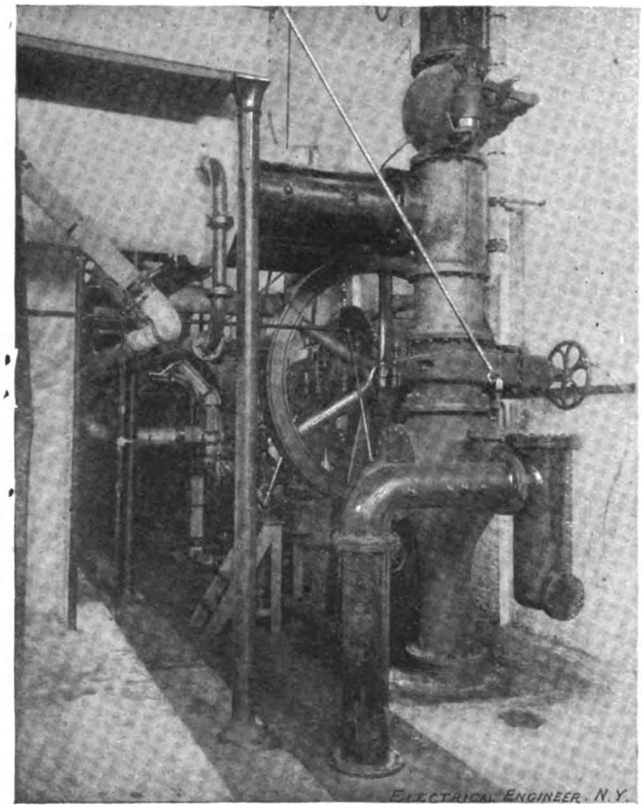
The generators are direct-connected, one to each engine, and are of the latest multipolar type, built by the General Electric Company. They are of 1,000 k. w. capacity each, and will carry a temporary overload of 40 per cent. if necessary. They are slightly over-compounded in order to raise the voltage during heavy loads. Space has been left in the engine room to provide for the installation of a third engine and generator of similar size whenever it becomes necessary.

A Westinghouse air pump is used to provide an air-blast for cleaning the generators and removing the dust from the armatures.

THE SWITCHBOARD.

The switchboard is on a raised platform at the north end of the engine room, and commands a view of the generators. At one end of this platform is the office of the chief engineer of the plant. The platform is reached by a set of iron stairs. Brass railings protect all stairways and also the platform.

The switchboard is composed of two dynamo panels and seven feeder panels, manufactured by the General Electric Company. The panels are of ornamental polished slate, and contain the usual main and feeder switches, automatic circuit breakers and lightning arresters, together with direct reading ammeters and voltmeters, furnished by the Weston Electrical Instrument Company, of Newark, N. J. There are also installed on the switchboard two Thomson (Type G) recording watt-meters to register the total output of each generator.



Dorchester Plant, Boston West End Road, Conover Air Pump and Condenser.

All circuit-breakers are fitted with electric alarm bells, which ring continuously as long as any circuit-breaker is open. In the office is installed one Bristol recording voltmeter, which records all fluctuations of the voltage; one Crosby recording steam gauge, and a tide gauge. The station is connected by telephone with the central power station at Albany street.

In the corner of the building, underneath the office and on the engine room floor, are provided toilet rooms and lockers for the engineers and electricians. Underneath, on the intermediate floor, are storerooms and bathrooms, and on the basement floor are toilet rooms and lockers for the firemen and coal passers.

THE DESIGNERS, BUILDERS AND OPERATORS.

The whole plant was designed and carried out under the personal supervision of the master mechanic of the company, Mr. C. F. Baker, who is an experienced mechanical engineer, and the result is an evidence of his skill and untiring energy. Mr. F. P. Sheldon, of Providence, R. I., was retained as consulting engineer.

The contractors for the foundations, buildings and stack were Messrs. Whidden & Co., of Milk street, Boston, and for the fireproof roof, Messrs. Guastavino & Co., of Albany street, Boston; while the Boston Bridge Company supplied the trusses and ironwork, and also the traveling crane.

The operation of the plant is in charge of Mr. H. Gough, as chief engineer, who also superintended the installation work. He is ably assisted by the assistant engineers, Messrs. A. Warner, A. Fletcher and F. Morse.

The writer takes this opportunity of thanking Mr. C. S. Sergeant, the general manager of the company, and the other officers for the many courtesies extended to him in the preparation of this brief description.

ELECTRIC LIGHTING

CONDUCTIVITY OF INCANDESCENT CARBON FILAMENTS AND OF THE SPACE SURROUNDING THEM.—II.

(Concluded.)

JOHN W. HOWELL.

Fig. 4 shows a lamp having a platinum plate 2¼ inches long and ¾ inch wide between the legs of the filaments, and a wire inserted in the vacuous space. I also used lamps having a similar plate made of glass, similarly placed. In both of these lamps, when the vacuum was high, no current was produced between the wire and the positive terminal when the wire was shielded from the negative leg; but shielding the wire from the positive leg made no hindrance to the passage of the current. The facts that no current flows when the galvanometer is connected between the negative terminal of the lamp and the inserted wire, and that a shield between the positive leg and the inserted wire has no effect upon the current, show that positively charged molecules are not emitted by the positive leg; while the screen effects just described show that the negatively charged molecules pass in straight lines.

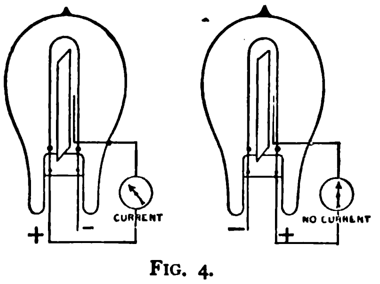


Fig. 4.

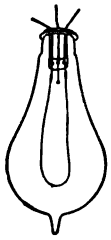

Fig. 5.

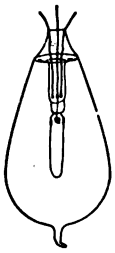

Fig. 6.

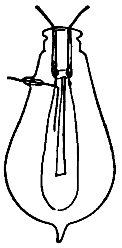

Fig. 7.

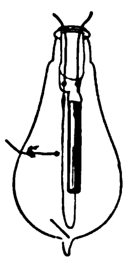

Fig. 8.

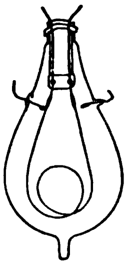

Fig. 9.

The facts, then, are these: The galvanometer indicates a current flowing, as we designate the direction of currents, from the wire to the negative leg; while experiments prove that the charged molecules which carry the current actually pass from the negative leg to the wire. These facts are entirely in accord with the results obtained by Crookes and others in their investigations of currents in high vacua.

If an alternating current is used to render the filament incandescent, the galvanometer will indicate a current with the connection made to either lamp terminal, because both are equally positive. The current thus produced is a uni-directional one in the galvanometer, and illustrates very well the uni-lateral conductivity between the incandescent filament and the wire.

The blue glow in lamps has long been associated in my mind with the condition of the vacuum which makes it a conductor. I observed several years ago, that at a high temperature .04 or .05 of an ampere, more current flowed through a lamp showing a good blue than through the same lamp, at the same voltage, when the blue had disappeared. I concluded that this extra current flowed through the vacuous space between the legs of the filament.

If a direct current about 20 or 30 per cent. greater than the normal current be passed through a lamp filament when the vacuous space shows a blue glow, the positive joint between the filament and the platinum wire gets red hot, while the negative joint remains cool. I have always considered this as proof that the resistance to the passage of a current through a vacuous space was chiefly at the surface of the positive electrode, as the energy was chiefly developed there. If an alternating current is used both joints get equally hot.

If a lamp be burned at normal incandescence with a direct current, when the vacuous space shows a good deal of this blue, the negative leg of the filament becomes coated with a carbon soot. This effect can be obtained in a few minutes if the blue is dense and the filament is run above a normal incandescence. This I have considered to be due to an electrolysis of a hydrocarbon gas in the lamp.

The lamps which show only a slight amount of this blue glow, if burned at normal incandescence, will not show this carbon soot perceptibly, and the blue will entirely disappear if the lamp is burned for a few hours. This blue is caused more by the character of the residual gas than by the degree of exhaustion.

In order to measure the currents which pass from one leg of the filament to the other across the vacuous space, I measured the current at a given voltage of a number of lamps; first when the lamps showed a good dense blue, before they were well exhausted, and again after the same lamps were well exhausted and showed no blue. Some 55-volt 24 candle-power lamps showed .4 of an ampere more on the first reading than on the second. All of this .4 of an ampere must have passed through the vacuous space, for the resistance of the filament remained practically unchanged or became a little lower during the operation.

I also measured the currents which passed across the vacuous space, when these currents were large enough to fuse the joint wire, and also when they were large enough to fuse both platinum leading-in wires. I found that from one to five amperes passed across the vacuous space and when the positive joint wire only was fused, and that when both wires leading through the glass were expanded so by the heat of the current that the glass was shattered, the current measured from 10 amperes to more than 25 amperes.

The lamp shown in Fig. 5 illustrates the fact that the heat produced at the positive joints by the "Edison Effect" current is not simply the result of a mechanical bombardment. This lamp was exhausted to show a good blue. The temperature of the filament was raised sufficiently to cause vacuum currents large enough to heat the positive joint red hot. The outer end of the middle wire was then connected to the positive lamp terminal. When this was done the positive joint became cool and the middle wire got red hot. This was repeated several times. The middle wire got hot enough to fuse the end, which was platinum. This indicates that most of the heat is caused by the charged molecules coming in contact with some conductor which will carry away their charge. The current was not measured in this experiment.

Fig. 6 shows the lamp used in a similar experiment. The middle wire carried a copper plate about 1 inch long and ¼ inch wide. This lamp was exhausted to show a good blue. An ammeter was connected between the middle wire and the positive lamp terminal. As the current was gradually raised, the vacuum current heated the copper plate until it was fused, as shown in the figure. The ammeter in this case indicated over five amperes flowing through the vacuous space between the negative leg of the filament and the copper plate.

I next tried a series of experiments to determine whether the current which passes through the vacuous space when the blue glow is present was the effect of charged molecules moving in straight lines only, from the negative leg, or whether this current would pass around a screen. For this experiment I used a lamp with a glass plate 2¼ inches long and ⅞ inch wide between the legs of the incandescent filament. It was necessary to raise the filament in this lamp to a very high temperature before the blue appeared, and then instead of appearing gradually, as it does in ordinary lamps, it appeared suddenly and in great abundance and the positive joint got red hot, so that it was necessary to reduce the temperature of the filament to prevent the fusion of the joint wire. As the temperature was reduced, the blue gradually decreased, as it does in ordinary lamps. In this lamp the blue appeared at 136 volts, and remained when the pressure was reduced to 109 volts, but would disappear between 109 and 101 volts.

My next experiment was with a lamp (shown in Fig. 7) having a platinum screen between the legs of the filament and a platinum wire sealed in the side of the bulb and projecting in the vacuous space, with its end bent so as to run parallel with one leg of the filament for about 1 inch between the filament and the platinum plate. When this filament was heated to about a 2½-watts-per-candle temperature, the vacuum current did not pass around the screen and no blue showed in the vacuous space. That leg of the filament being negative which was on the same side of the screen as the wire which was sealed into the bulb, I connected the galvanometer between this wire and the positive lamp terminal. The galvanometer showed a strong current. On breaking the galvanometer circuit, blue appeared on the positive joint and in the bulb. I repeated this several times. It occurred when the temperature was considerably below the temperature necessary to start the blue around the screen.

In each case, connecting the galvanometer between the wire and the positive terminal would cause blue to appear about the inserted wire and the negative leg, and breaking the galvanometer circuit would cause blue to appear on the positive joint, and in the vacuous space about the positive joint, and about the negative leg of the filament.

With this same lamp I observed that when the filament was at a temperature not sufficient to start the blue, if I touched the positive terminal with one finger, and the inserted wire with the other, the blue immediately appeared in the vacuous space about the positive joint and the negative leg of the filament.

These experiments demonstrate that in lamps exhausted so as to show a good blue, the charged molecules have some difficulty in starting their passage from one leg to another around an obstacle, but maintain their passage after it has been once established. Also, that their passage around an obstacle is easily established by starting a flow of charged molecules from the negative leg through a small unobstructed part of the vacuous space, to an inserted wire which is connected to the positive terminal, and then breaking the positive terminal connection.

To determine how large a current could be made to flow around an obstruction in lamps exhausted to show a good blue, I used a lamp shown in Fig. 8, having a glass tube about the negative leg, and the wire sealed in the side of the bulb, running parallel with the positive leg for about 1 inch. I connected an ammeter between the inserted wire and the positive lamp terminal, and raised the temperature of the filament until a dense blue appeared in the vacuous space, and about the wire and the end of the glass tube. The temperature of the filament was raised until the vacuum current fused the platinum wire which was sealed into the bulb. When this occurred, the ammeter indicated 2¼ amperes, and remained at this reading one or two seconds.

Any of the lamps in which the condition of the vacuum is just right, showing the blue glow, will show a current in a galvanometer connected between the wire inserted in the vacuous space, and the negative lamp terminal, but in all cases this current is small. One-half milliampere is the largest current I have observed under these conditions.

I next tried some experiments with lamps like the one shown in Fig. 9, which has two wires sealed in opposite sides of the bulb, which project inward to a point near the filament about ¼ inch above the joints. This lamp was exhausted to show a good blue. The galvanometer was connected between the wires which were sealed in opposite points of the bulb. No current was indicated until the temperature of the filament was raised quite high, and the blue glow was quite intense.

Under these conditions the galvanometer indicated a current of .1 milliampere.

I have made experiments upon two lamps containing bromine vapor. One of these lamps which contained bromine enough to depress the barometric column 1/20 inch, showed no "Edison Effect" when the potential was run up as high as 170 volts, using 110-volt lamp.

The second lamp had very much less bromine vapor in it, and showed a very slight "Edison Effect." This lamp acted very peculiarly. When first tried it gave an "Edison Effect" which changed very little in value between 105 and 146 volts. At 120 volts, the vacuum current showed a deflection of the galvanometer of 14 scale divisions, while at 128 volts it showed a deflection of only 12 scale divisions. I observed this several times. This was quite a large reverse change, as the current at 146 volts only increased enough to give a deflection of the galvanometer of 16 scale divisions. This change was observed on several days, but it was less marked each time it was tried, until it finally disappeared.

The question naturally arises, What causes the blue glow in the vacuous space? The glow is luminous, and luminosity can only come from matter; consequently, we conclude that the vacuous space, when blue shows, is filled with luminous molecules, and as these molecules are not of themselves luminous, we must seek for the cause of their luminosity.

We have seen that the negatively charged molecules liberate considerable energy on coming in contact with a body that conveys away their charge. We have also seen that when the blue glow is present there is a considerable flow of charged molecules through the vacuous space, and that the naturally rectilineal movements of these molecules are disturbed.

We also know that molecules are emitted from the positive leg about as plentifully as from the negative leg, although these molecules do not carry a positive charge.

The conclusion seems to be that the blue glow is a manifestation of the energy developed by the meeting of the charged molecules with other molecules which take away part or all of their charge.

Well exhausted incandescent lamps which have burned a long time show a black deposit on the inner surface of the bulb. In lamps with thick, stiff, single-loop filaments, in which the two legs lie in the same plane, a light line may be observed in the black deposit, which is caused by the shielding of this line by one leg, from the molecules emitted by the other leg. This line shows with about equal clearness opposite both legs, indicating that carbon molecules are constantly emitted from both legs, equally and in straight lines.

In lamps which have been imperfectly exhausted, the black deposit sometimes appears in patches, symmetrically placed with reference to the carbon. I regard these figured discolorations as indications of disturbances in the rectilineal paths of the molecules, and of the influence of the magnetic field upon the disturbed molecules.

The activity of the molecules carrying current across the vacuous space seems to depend more on the temperature of the filament than on the potential difference between the legs, 40-volt lamps showing about as strong effects as 140-volt lamps. The energy they exhibit in one direction seems to be very much greater than we would expect from molecules actuated by a potential difference of only 40 or 50 volts. The action of these molecules in carrying electricity in one direction only, may be an indication of the nature of the action between molecules in solid conductors carrying currents, rather than an illustration of the action of statically charged molecules.

MUNICIPAL LIGHTING REPORTS.

BY GEORGE S. THAYER.

THE recent municipal number of The Electrical Engineer contains a very instructive example of the methods of gathering statistics intended for the information of town councils. The report recently made to the city of South Norwalk, Conn., is a little out of the ordinary run in the amount of detail. Voluminous, impartial and apparently complete, it must be considered a failure if presented in its present shape to men unacquainted with the factors which enter into the cost of running a central station.

A comparison of the report with that of Horatio A. Foster on the data collected by The Electrical Engineer a couple of years ago[1], shows the reason for the apparently excellent showing made. Not only do the cities as a rule neglect interest, but they quite uniformly neglect the day of reckoning which is sure to come when the equipment is worn out or reaches such a condition that the entire plant needs to be rebuilt or remodeled in order to adapt it for economical operation under changed conditions, conditions which could not have been foreseen at the time the plant was installed. A business man who does not know what it is costing him to do business may succeed, but the chances are against him. The same is true in electric lighting, private or municipal. When some of the large central stations find it necessary to set aside 10 per cent. per annum as depreciation it seems strange that there should be such a tendency to neglect this item. If the plant is paid for, interest cuts no figure at all. If a man buys a home to save paying rent, in figuring up his saving he most certainly offsets the interest on the money invested, whether or not he has paid for it. There is no reason why a city should not look at interest in the same light.

---

[1] See "Electrical Engineer," Sept. 15, 1894.

If the influence of these reports were confined to the place in which they were written the injustice to private plants would not be so great; but unfortunately such is not the case. They are quoted by dissatisfied citizens whose towns are supplied by private plants. The result is bad feeling between the parties concerned and often the reduction of the price of street lighting to below the real cost. Unless the station manager is prepared to expose the errors in these claims, every such report becomes a standing menace to his plant.

The editor of a local paper here fought with might and main a few years ago against the price received by the writer's plant for street lighting, quoting as his authority a table published in the Review of Reviews giving some costs of lighting under municipal ownership. I am told that he made a strong point of the fact that Marshalltown, Iowa, 35 miles west of here, operated 64 2,000-candle-power arcs all night on moonlight schedule for $14 per year, the plant being independent of the water works. A new contract was obtained at a lower price with a pretty general impression that there was big money in it for the plant. Other stations have had similar experiences.

The general conviction at the last meeting of the Northwestern Electrical Convention seemed to be that the remedy for these methods of estimating costs in municipal plants is to get at the real facts and give them the widest publicity; in the words of the politicians, conduct a campaign of education. The average town is willing to be fair in its treatment of its electric lighting company. They do not understand why everything over operating expenses is not profit, and they are strengthened in their belief by the system of accounts adopted by cities which own their plants.

The reports of municipal plants show upon analysis that the cost of furnishing current is subject to wide variations. Especially is this so in plants under 200 horse-power. This includes the majority of municipal plants. The cost of labor bears but little relation in small plants to the station output, which may vary 50 per cent. either way, affecting little outside of the coal pile.

But after all the worst feature of the municipal lighting management is the almost universal underestimating of expenses when looked at from a business standpoint. I want to take up one of the plants in this report, not as a sample of city plants, but as one which presents the difference between the reported and the actual cost.

The case is that of Lisbon, a small town in Eastern Iowa. The plant consists of one 100-horse-power Buckeye engine and one 1,000-light Fort Wayne alternator, running 14 2,000-candle-power street, 8 2,000-candle-power commercial arcs, and 500 incandescents. Another item of 1,400 incandescents is apparently a typographical error[2].

The annual income comes within $125 of meeting operating expenses. They are evidently well pleased with the showing they made. Their mayor adds, among other things: "A more foolish thing a city could not well do than to give away a franchise for a lighting plant." The cost of the plant is not stated, but I understand it is $15,000. Allowing 5 per cent. interest on the investment, or the interest on the bonds and depreciation on a 15-year basis, their arcs are costing them $133 a year. Even with depreciation on a 20-year basis the cost is $107 per year. These figures are for a midnight arc.

That town will be quoted as running 14 arc lights at an expense of $125 per year, a little better record than that of Marshalltown, and the private plants in that section of the country will be reminded of the fact when their city contract is about to be renewed. There is no doubt that the plant is economically operated and private consumers get their lighting at lower rates than they would under private ownership. But the report is wholly misleading. The plant has been in operation about two years, and repairs as yet are nominal. It will not always be so.

The experiences of two towns in this State are interesting, as showing the final outcome of this policy. Several years ago Leon, a county seat in Southwestern Iowa, decided to put in a plant of its own. At the end of the second year they pointed with pride to a surplus that was accumulating. Last year the citizens voted to shut down and sell it rather than to make the necessary repairs. They found the city had no power to dispose of the plant without action by the Legislature. Audubon came to the same conclusion in regard to its plant, and had actually turned it over to the purchaser, who began operating it. At last reports, they had not found a way to transfer their respective interests.

In view of the fact that many other towns have had similar experiences, it seems strange that none of them found their way into the South Norwalk report. There are some thirty municipal plants in this State, the majority of which are in small towns where there is no private plant. Most of them have been built within the last five years. They are therefore in the period where they make the most favorable showing as regards operating expenses, the item which goes as "cost" of lighting!

As a central station man, I have little to fear from municipal plants. Our citizens are under the impression that we are making money hand over fist. Our rates compare very favorably with those of the neighboring municipal plants. We expect to prove by their reports that we are not. To do this, however, we must have something more than the usual statement that it costs so much to run light in a certain city plant. If city plants can show such remarkable results as are claimed, I want to know how they do it and apply the same methods to my own plant. If they cannot, I am still the gainer, because we are not placed under the odium of robbing our customers by abnormally high rates.

The electrical fraternity is watching with some interest the steady climb in the reported cost of arc lighting in Detroit. Mayor Pingree gave out the figure last summer as $65 per annum. Later on some city official gave it as $75, or near that. According to the last convention of the American Society of Municipal Improvements, the cost was $84.70. Where will it stop?

There is no reason why a city cannot operate its plant as cheaply and save the profit that private ownership would require except the difference between what American politics might be, and what they really are. As long as the best citizens are adverse to holding office, so long will municipal affairs be managed by second-rate business men, with corresponding results. There seem to be indications of a change in the sentiment towards municipal ownership as time goes on, and the true cost of operation becomes apparent. Some of the former advocates have changed their minds on the subject, and we have the statement from Mr. W. J. Buckley, of the Fort Wayne Electric Corporation, a gentleman who has had extensive experience in city plants, that he has come to the conclusion that municipal ownership does not pay.

Bell Plaine Electric Company,
Bell Plaine, Iowa.

MISS HIGHTOWER "PRESSED THE BUTTON."

A special dispatch from Barnesville, Ga., says: The electric lights were turned on to-night at 6 o'clock by Miss Willie Hightower, who was selected by Mayor G. E. Huguley to start the machinery. Every citizen has been watching the work, anxious for the time to come to turn on the lights and to make a big night of it for Barnesville, and a big demonstration was made. Crowds went to the plant, while the streets of the city were lined with people.

Miss Hightower invited a party to accompany her to the plant in a carriage. The city council and city officials were all there, and Mayor Huguley made a speech concerning the enterprise, pluck and energy of the city, which has all the modern conveniences, and then introduced Miss Hightower, who responded in a most happy style. She said: "In the beginning God said 'Let there be light,' and swift, obedient to His command, the roseate hues of creation's dawn gladdened the divine heart of Him who spoke as never man spake. Then the morning stars sang together in the rhythmic music of the spheres. This evening, under the quiet stars, while expectation waits on tiptoe to catch a glimpse of the electricity of the skies, harnessed to wires, we would delay this momentous, but happy, consummation just a moment to pay a short tribute to the enterprise, energy and laudable public spirit of our wide-awake mayor and council. Our little city is already abreast with the most aspiring, and the electric plant is a shining memorial to Barnesville enterprise. My thanks are specially due Mayor Huguley for the honor conferred upon me, and it is highly appreciated. May we all ever more walk in the light, the beautiful light.

"Hail, holy light!
Offspring of heav'n first born.
God Himself is light."

Miss Hightower then pressed the button; the lights instantly flashed over the city, and a yell went up for Mayor Huguley, the city council, Miss Hightower and electric lights. Miss Hightower's party then repaired to the home of Mr. and Mrs. J. W. Hightower to an eleborate 8 o'clock dinner.

ROENTGEN RAYS

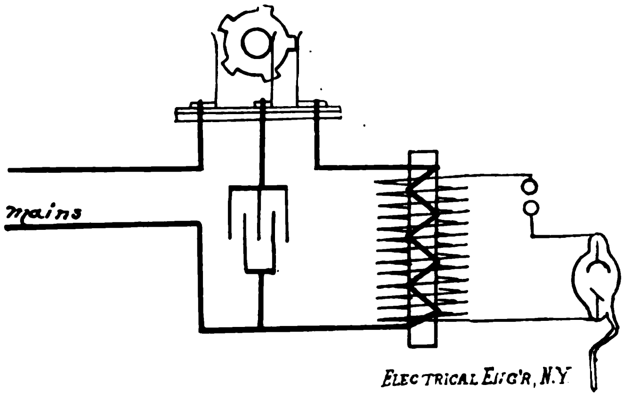
A POWERFUL MEANS FOR OPERATING X-RAY TUBES WITH AN INDUCTION COIL.

BY CHARLES L. NORTON AND RALPH L. LAWRENCE.

We have been using in our laboratories for the last few weeks a method of operating X-ray tubes with an induction coil, that possesses some novel features. Our experience had led us to entirely discard all other induction coil methods as being much inferior to the static machine. The most troublesome feature of the ordinary apparatus is the break in the primary circuit, no one of the various forms having proved equal to continued service of 110 volts. Storage batteries are troublesome, and neither efficient nor convenient for this work.

If a condenser be charged from the lighting mains at 110 volts or 220 volts direct, and then disconnected from the mains and discharged through the primary of an induction coil, there will be in the primary of the coil a current of short duration which will rise to its maximum with great rapidity, aided by the reaction of the secondary, and will then fall slowly, being retarded by its own reaction. This is the ideal condition to give a undirectional discharge of great potential at the secondary.

If now by means of a commutator we can connect the condenser alternately to the mains and to the coil, and if the terminals of the secondary be brought near enough to one another, there will be a spark at its terminals for every discharge of the condenser through the primary. By mounting the commutator on the shaft of a small motor, we charge and discharge the condenser 200 times a second, thus getting a perfect torrent of sparks.



Arrangement for Generating Powerful X-Rays.

Using a Ritchie 6-in. coil, with its primary winding replaced by one of thirty turns of wire of No. 8 B. & S., and discharging through its primary a 25-microfarad condenser charged from the outside wire of the three-wire lighting system at 220 volts, we get at the secondary terminals a torrent of sparks about six and one-half inches long, accompanied by a loud scream of such a pitch as to indicate that there are about 250 discharges per second.

The connections are indicated in the accompanying diagram.

The insulation of the primary and secondary from each other and from the core, and even of the consecutive turns of the primary from one another, is of great importance. The use of a glass tube to contain the primary, immersed in oil, has proved efficient. It is highly essential that the iron core should be finely divided, as a single piece of iron wire one-quarter of an inch in diameter causes a diminution of 75 per cent. in the discharge. The coil will work without the iron core, but not as well as with one of fine wire.

Connecting to the terminals of the coil a focus tube with a spark gap in series, we find that the tube emits powerful X-rays. An exposure of one second is sufficient to give negatives of such small objects as coins in a purse, and five seconds gives a negative of the hand which is sufficient for the purposes of examination of the bony structure by a surgeon, while twenty seconds gives a negative which is the best we have ever seen. Forty-five seconds gives an over exposure. But it is not the speed so much as the sharpness and delicacy of outline that is most worthy of attention.

Examination with the fluoroscope shows exactly the details of the bony structure of the trunk, the action of the heart, and the outline of the lungs and liver.

The resistance of X-ray tubes of the focus type may be varied at will by running them on the coil in the proper direction. A tube of rather low resistance, if connected to the coil in the usual way, with the spark gap on the cathode side, will increase in resistance quite rapidly to the point where the platinum anode becomes red hot and X-rays are given off powerfully. The increase is most rapid with closed spark gap. Beyond this point the change, although an increase, is slow.

It is very often the case that a tube, which has been run for some time on the coil, when removed and allowed to cool, will increase in resistance to such an extent that it will be impossible to use it again satisfactorily on the coil. If, however, the tube now be connected to the coil, making the concave electrode anode, and allowed to run a few minutes, the resistance will be reduced. A slight warming with a Bunsen burner will facilitate matters. The action of the coil in raising and lowering the vacuum in tubes is very similar to that of static machines. The power with which a tube will emit X-rays depends very much on the adjustment of the spark gap.

The method appears to require apparatus of simple construction, and of such ease of manipulation that it may serve well in the hands of physicians, and others not especially skilled in the manipulation of physical apparatus. It is a method independent of the atmospheric conditions, and can be used wherever electric lighting mains are accessible.

Rogers Laboratory of Physics,
Mass. Institute of Technology, Boston, Mass.

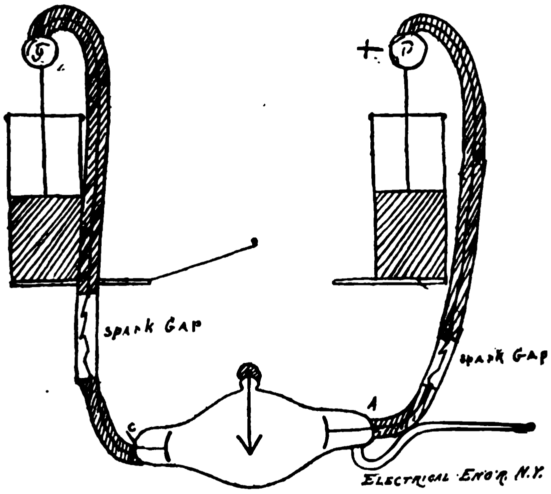
(The authors have sent us photographs of a purse with coins taken in a one-second exposure, and also of a hand exposed for twenty-three seconds. Both of these equal, and in some respects exceed, in excellence of detail any radiograms which have thus far come under our notice. No reproduction could do them justice.—Eds. E. E.)

X-RAYS BY STATIC ELECTRICITY.

BY O. C. WELBOURN, M. D.

It being designed that this article should be as short as is possible, to be practical, no attempt will be made to give observations or arguments through which the conclusions given were reached. The more important parts will be placed under appropriate heads to facilitate description and comprehension.

The Static Machine.—This should be strongly made, smooth running and capable of high speed.



Spark Gap Arrangement for X-Ray Production.

An electric motor is much better than hand power and a glass protecting case is almost essential, unless the machine is to be used in a very dry atmosphere.

A 10-inch spark is sufficient e. m. f. for any purpose and a 6-inch does nicely for all parts of the human body except the trunk. The careful operator will see that the bearings are well oiled and the brushes, combs, revolving plates, etc., are in proper position.

Spark Gap Connections.—If the Crookes tube be connected by a well insulated wire to the internal armatures of the Leyden jars, the switch connecting external armatures being open, and a proper length spark gap, inclosed in a glass tube, inserted at both anode and cathode ends of the tube, as shown in the accompanying illustration, X-rays will be produced as steadily as by any induction coil that I have had the pleasure of witnessing, and they will be very efficient for fluoroscopic use. Sometimes the external armatures of the Leyden jars continually discharge through the wooden base and it is necessary to remove them, making connections directly to the poles of the machine. Close the switch and you will have a slightly more intense ray, at the instant of the discharge of the jars, which is very efficient for skiagraphic purposes. By grounding the anode wire a relatively higher vacuum tube can be used. The length of spark gap depends, of course, upon the degree of vacuum in the Crookes tube, but as a rule should be twice as long at the cathode end as at the anode.

Crookes Tube.—The most satisfactory tube that I have used is a Thomson double-focus tube, made by the New York and Ohio Company. I have used it for over three hours continuous running without heating, and over one hundred hours in all, without any perceptible change of vacuum, and just a trace of blackening.

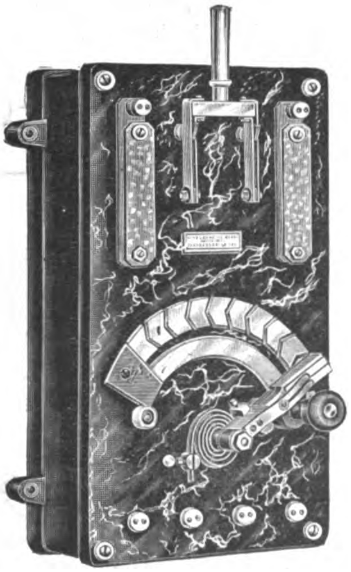
Dry Plates.—In my experience, a slow, dry plate takes about as quickly as a very sensitive one, and one is not bothered with foggy plates. Develop and fix in the usual manner

It is not easy to over-develop when the negative is to be used for printing; but in surgical work it is sometimes well to rinse and place in a weak "hypo" as soon as the image begins to fade. It is then ready for immediate inspection and the image will be found sharp and clear.

A great many persons have been exposed to X-rays as I thus produce them—some for an hour and a half—and not one has had the slightest inflammatory action follow.

THE C & C MOTOR STARTING BOX.

In order to meet the rules of the New York Fire Department relating to electrical installations, the C & C Electric Motor Company has recently brought out a novel motor controlling box, illustrated in the accompanying engraving, This neat apparatus embodies a high and low resistance starting box, together with a double pole knife switch and fusible cut-out, also mounted on the marbleized slate plate forming the front of the box. The resistance consists of coiled wire open to the air.



The C & C Motor Starting Box.

The pivoted contact bar is made up of two parts, one forming the contact arm proper, and the other, with which it is loosely connected, serving as the iron armature of an electromagnet placed on the other side of the slate. The contact arm is pivoted on one pole of this magnet, while the other is placed at a slight radial distance therefrom, and acts as a stop for the iron armature, which strikes against it when the resistance is all cut out.

The magnet which controls the arm is wound differentially, one of the windings being in series with the armature, while the other is in series with the shunt field. Closing the main switch and moving arm to the right, connects the field of the motor and cuts out the armature resistance. This increases the motor speed, and the maximum is reached when the iron arm strikes the stop and is held there by the magnet. The windings of the magnet are arranged so that under normal conditions the winding in series with the shunt field overbalances the other until the predetermined overload limit is reached, at which point the increased current in the latter neutralizes the magnetic effect, and releases the contact arm. An open circuit produces the same result. This starting box may be operated with or without the overload feature.

It will thus be seen that this starting box not only starts the motor, but also protects it from damage by overload or current interruptions. One of these type F. starting boxes is furnished with each C & C motor.

WATER-POWER FOR TRANSMITTING ELECTRICITY TO WINSTON-SALEM, N. C.

Arrangements have been completed for the electrical development of water power on the Yadkin River, near Winston-Salem, N. C. The Fries Manufacturing and Power Company, of Winston, is promoting the development, and has engaged Messrs. C. R. Makepeace & Co., of Providence, R. I., to prepare plans and superintend the work. Mr. H. E. Fries is treasurer. The company expects that at least 1,000 h. p. will be delivered over the wires into Winston-Salem not later than August 1 of this year. The distance the power will be transmitted is fifteen miles. The present development will be for 2,000 h. p., and at the price which the company expects to be able to sell the power its use will, it is claimed, be very general in Winston-Salem. The Messrs. Fries are interested in several cotton mills at Winston-Salem, and these mills will be the first manufactories to use the power when it is ready for service.

A CALIFORNIA ELECTRIC POWER SCHEME.

A corporation to be known as the Southern California Power Company has been organized with a capital stock of $1,000,000. The principal stockholders are Henry Fisher of Pittsburg, Pa., and H. H. Sinclair, president and manager of the Redlands Electric Light and Power Company. The present place of business of the corporation is Redlands. The purpose of the company is to develop power from the Santa Ana River by taking the water out at the junction of Bear Creek and Santa Ana River, carrying it in a cement ditch and tunnels about four miles, thus securing a fall of 1,000 to 1,100 feet, and then running the water again into the stream. The power will be transmitted by pole line, seventy-five miles to Los Angeles, there to be used for lighting and railroad use. It will be the longest line and the highest voltage (30,000 volts) in use in the world. The line will run through San Bernardino, Pomona, Ontario, and Pasadena, and will be able to supply all the power needed in these towns. Work will begin in the Santa Ana cañon as soon as the surveys are completed, which will be about April 1. It is proposed to deliver power in Los Angeles by January 1, 1898. A good deal of successful electric power work has already been done in the vicinity.

THE FRESNO TRANSMISSION.

The success of the operation of long distance electrical transmission is perhaps best gauged by the opinion expressed by the company operating the plant. An extract from a recent letter regarding the operation of the Fresno, Cal., long distance transmission may be interesting to our readers. It was written by Mr. John J. Seymour, President of the San Joaquin Electric Company, operating the San Joaquin River by Fresno transmission, to the General Electric Company, which installed it: "It affords me great pleasure to write you regarding the successful operation of the long distance transmission plant installed for our company. The entire plant as furnished has been in actual practical operation for a period of several months. The thirty-three miles transmission has given us no trouble whatever. Our load at present consists of 145 arc lights and 5,000 incandescent lights and 410 h. p. in motors, the latter including 180 h. p. for the Sperry flour mill and 75 h. p. for the city pumping plant. All of the machinery doing this work has worked with perfect success from the start. The incandescent lights have most of them been newly wired in, thus enabling us to properly balance the load and the regulation has given us no trouble whatever. During extensive tests it was impossible to find more than two volts' variation between any lamps on the system. Lights so furnished seem to me to be better than incandescent lights usually furnished in San Francisco and other cities of the State."

LETTERS TO THE EDITOR

UNDERGROUND TROLLEYS AS A PREVENTION FOR ELECTROLYSIS.

AT the recent Gas Exhibiton held in this city there was shown a group of exhibits which to a thoughtful insurance underwriter should have given rise to very serious reflections as to the final outcome of the much-mooted question, What shall we do with the overhead trolley sytem?

The exhibits referred to were a collection of gas and water pipes removed from streets through which overhead trolley systems of electric traction are in use. The evidence presented by them should prove beyond peradventure, that something should and must be done to stop the present dangerous practice of ground returns, as used by nearly, if not quite, all the present roads in operation.

The citizens of this city have recently read of the efforts of the Third Avenue Railway Company through its lawyers to prevent the Metropolitan Railway Company from extending its system of underground trolleys, using as one of its reasons (for opposing the permit by the city to the company to so extend the underground system) that the trolley system would cause electrolysis, etc., but it is to be hoped that any such rot as this will avail nothing, and that not only will the mayor permit the proposed extensions, but that he will suggest the removal of the now dangerous overhead trolley system that has obtained a foothold in the upper part of the city, and try and have a system of underground traction substituted.

New York.

ELECTRICAL ENGINEERING ON CONVERTED STEAM ROADS.

I NOTICE in The Electrical Engineer of March 10, a communication bearing on some of the electrical engineering work of the New York, New Haven and Hartford Railroad. I also notice a report of President Clark's address before the Connecticut Legislative committee on railroads, in which he discovered that competent electrical engineers were at variance as to whether the current passed through the conductor or on the surface. Also that contrary to all prophecies by engineers (his own included, I suppose), there was less leakage on the Nantasket trolley line than on most street railways, and that in this respect the third rail experiment was a decided success.

As the power station No. 1 was open for inspection to interested parties, I had the pleasure of looking over the plant during its first and second seasons and was deeply impressed with the thorough understanding of the steam and electrical problems as demonstrated by the electrical department of the road. For instance, copper and iron seem alike to be used as magnets on the common circuit breakers on the switchboard. This is certainly an advance in this line of instruments. Again, at a time when no trains were in service, which happened quite frequently, the wattmeter still ran its merry course, showing, of course, "no leakage." That there was no leakage on the third rail, can, no doubt, be attested by residents of Hingham and by dumb animals, as well, who, if they would speak, could tell the effects of a difference of potential, even if they could not state whether the current went through, or on the outside of this wonderful third rail, the acme of electrical railway practice.

Returning to the trolley line: I was very much surprised at the turns and twists in the special figure of 8 wire, but it is wonderful how well the wire was put up if all the wire was received on the small four-foot reels which I noticed. Again, I observed that no proper alignment of the trolley wire was possible with the form of cross-arm used.

Remove these and other defects in construction and I see no reason why the highest speed should not be obtained satisfactorily with the overhead trolley. It seems strange, as remarked by "Electrical Engineer" that a railroad of such high standing should not employ the best electrical talent in the country. ANOTHER ELECTRICAL ENGINEER.

Boston, March 17, 1897.

THE RECENT CHANGES IN THE PATENT LAW.

WE call your attention to the fact that certain changes are made in the United States Patent Laws by a recent act of Congress, the main provisions of which will go into effect January 1, 1898.

Particularly we call attention to the radical changes made in Section 4887 of the Revised Statutes affecting the interests of those taking out, or desiring to take out, foreign patents. The section, as revised, reads as follows:

"Section 4887. No person otherwise entitled thereto shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented by the inventor or his legal representatives or assigns in a foreign country, unless the application for said foreign patent was filed more than seven months prior to the filing of the application in this country, in which case no patent shall be granted in this country."

It will be seen that the long-standing requirement that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent," is to be abolished, so that under the new law inventors can apply for their foreign patents without waiting for the allowance or arranging for the issuance of their corresponding United States patents. On the other hand, there has been added a limitation whose effect is to cause a foreign patentee to forfeit his right to a United States patent unless he files his American application within seven months after the filing of his application for foreign patent for the same invention.

As the amended section of the law will not go into effect until January 1, 1898, and will not "apply to any patent granted prior to said date, nor to any application filed prior to said date, nor to any patent granted on such application," those having foreign patents for inventions not yet patented in the United States of America still have opportunity, until the first of the coming year, to protect such inventions in the United States under the old provisions of the law.

HOWSON & HOWSON.

Potter Building, New York City, March 12, 1897.

NEWS AND NOTES.

SUGAR FROM CORNSTALKS BY ELECTRICITY.

Considerable curiosity is shown as to the organization of a new sugar company, as reported in the newspapers, with a capital of $50,000,000, all of which, it was said by persons in a position to know, is intended to be used immediately, otherwise the company would not at once have paid the State the full fee of $10,000 on that amount of capital named for the privilege of organization. An effort to conceal the real purpose of the corporation was made by alleging that the only object was to make use of the products of cornstalks, such as corn-pith cellulose for car wheels, etc., but the main object of the company, it is said, is to manufacture sugar by a patent electrical process invented by Mr. Marsden, not only out of cornstalks, but out of other raw material not specified, and that some of the well known sugar refiners are really interested in the company. It has been demonstrated that sugar can be made out of cornstalks, and if the Marsden process for doing so by electricity proves to be an economic success as well, it may be a new departure in the sugar refining industry. The inventor of the electrical process is Mark W. Marsden, and the corporators of the company are Richard C. Ellis, John McCormick, Peter H. Evans, and James A. Clark, all of Philadelphia, and John R. Williams, of Merchantville, N. J. One of the provisions of the articles of incorporation is that no stockholders shall have the right to examine the books, vouchers, etc., of the company, except by resolution of the board of directors. "Electric Sugar" is a phrase of ill-savoring repute owing to the frauds perpetrated some years ago by those who claimed to be making sugar that way.

VOL. XXIII. NEW YORK, MARCH 24, 1897. No. 464.

ELECTRIC POWER IN MANUFACTURING ESTABLISHMENTS.

THERE is no more conservative class of individuals than the owners of manufacturing establishments who cling to old and well tried methods with a tenacity that has been the despair of many an inventor. Even when one of their more enterprising brethren has ventured to lower the bars and has achieved success by improved methods, others have been slow to follow of their own accord and have indeed in many cases been driven towards the new idea by the stress of competition. The adoption of improved machinery for turning out product has in the majority of instances involved the mere abandonment of old and perhaps worn-out devices and has not, as a rule, called for so radical a change as to require a remodeling of plant, but it must be admitted that the suggestion of a change of motive power, the prime source of all shop activity, cannot but strike the average manufacturer as a thing hardly to be thought of. And yet, in spite of the momentous nature of such a change, we know of no idea which has been seized hold of and grown in favor so rapidly as has the substitution of electrical for mechanical or belt transmission in manufacturing establisments of all kinds. We are well aware that the percentage of electrically driven establishments as compared with those of the old type is still small, but the aggregate capacity of the electric motors now running machinery in shops and manufacturing establishments, not to speak of mines, amounts to many thousands of horse power.

The time that has elapsed since the new system of machine driving has gone into use is now sufficiently long to afford an answer to the question, Does electric power in manufacturing establishments pay? It is this query, in fact, which Prof. D. C. Jackson, of the University of Wisconsin, has made the subject of an admirable and concise paper read before the Western Society of Engineers.

In order to get at the facts he submitted a series of questions to a large number of manufacturing establishments throughout the country, varying in the extent of the electric power applied, from 50 to over 1,500 horse power. The results of his inquiry are embodied in his paper.

Prof. Jackson discusses the subject under two principal heads: (1) Comparative first cost; and (2) comparative operating expenses. Under the first head Prof. Jackson's information goes to show that the original introduction of electrical transmission in a new establishment which has its own independent and complete power plant, is always considerably greater than the first cost of mechanical transmission, such as by gears, shafting, belts, etc., even taking advantage of the fact that the higher efficiency of the electrical plant permits of a reduction in the total capacity of the steam plant when electricity is used. This being the case, we are at once brought face to face with the fact that the electrical equipment must effect an annual saving to pay a profit on its extra first cost, or it has no reason for its existence. The latter consideration, of course, applies with special force to the cases of established concerns, where old machinery must of necessity be abandoned, with consequent additional loss.

It will thus be evident that electric motive power was not ushered into the world of hard practice on a path of roses. What then are its merits that have caused it to thrive and increase in the face of that great damper upon enthusiasm, higher price? These must be looked for under the head of operating advantages, and Prof. Jackson has divided them into various classes. Taking up first the annual expense for fuel and attendance, Prof. Jackson quotes from the replies received by him from representative establishments many highly interesting letters which would take too much space to give in detail. Many, unfortunately, give only general results owing to lack of records, but those that do quote figures present, in the majority of cases, a most gratifying, in fact, an astonishing record of economy. Thus, for example, one concern notes a fuel economy of 33⅓ per cent., on a plant no larger than 185 horse power. Other concerns report increased economy, but without giving definite figures. We note, however, that one concern having an electrical power plant aggregating 1,537 horse power, has "no appreciable difference" in fuel cost, although no records have been kept. From internal evidence, we judge that the electric plant forms only a part of the power equipment of this concern, and as no records were kept the information imparted can hardly be of much practical value. Coming to the annual expense for repairs, and frequency and extent of failures, the record is still more encouraging. One concern notes a saving of 25 per cent.; another of 75 per cent. Breakdowns are extremely rare; one concern notes only two in five years, and these are now absolutely guarded against by duplicate armatures kept on hand. Another establishment whose plant was laid out by a competent electrical engineer, and is in charge of an electrician, has never had a breakdown. This same establishment, however, seems, curiously enough, to be under the impression that its electric power plant shows no economy over mechanical transmission, as it is so extensive as to require an electrician to look after it, who also has charge of the lighting plant! Prof. Jackson sums up the considerations above treated as follows: "It is safe to say that there is an overwhelming feeling in favor of the use of electrical transmission in preference to the various forms of mechanical transmission on the combined score of economy of operation and a reduced annoyance and expense through delays caused by failure of transmission apparatus. In nearly every case for which exact figures were given, a sufficient direct saving was shown to make large returns on the increased first cost of the electrical equipment."

When we come to the matter of convenience, Prof. Jackson's inquiry proves the almost universal experience that in establishments turning out a product of bulky or heavy articles, the electrical equipment adds materially to the shop efficiency. On the other hand, in establishments where the product is in small articles and where cleanliness is important, the electrical equipment adds to the shop efficiency more largely through cleanliness.

The experience in all establishments which have come under the notice of Prof. Jackson leads him to conclude that for plants using not less than 100 horse power the electrical transmission is so much more satisfactory and economical that it is a misfortune for a new manufacturing plant, unless under very exceptional conditions, to be constructed with any type of transmission other than the electric. Prof. Jackson also discusses another important point bearing on the question under review and that is, the subdivision of power at the machinery. Thus it seems to be the general consensus of opinion among those who have operated electric power plants, that all large tools, such as use from 5 to 7½ horse power, and over, should be supplied with individual motors, while small tools or machines requiring less power should be grouped and driven from motor-driven shafts. These groups should ordinarily be arranged so that a motor of not less than from 3 to 5 horse power capacity is required, and not more than from 10 to 15 horse power.

It might be claimed that it required no testimony to prove the superiority of electric shop transmission at this late day. None the less, we consider Prof. Jackson's inquiry and his deductions therefrom among the most valuable, practical data on this subject that has come before public notice for a long time past.

HARMONY UNDER THE NEW HAVEN ELMS.

THAT the relationships between managers and men in industrial enterprises can remain pleasant through long periods, is evidenced by the recent little affair at New Haven, Conn., when the Street Railway Company gave its employés the third annual banquet. The reports in the local papers show it to have been an extremely enjoyable occasion, one episode of which was the gift to President Corey, by the men, of a handsome silver and gold tobacco box. We cannot help feeling that the road is well run by General Manager Dodge, and that the interests of the stockholders and the public are alike protected. When we find Superintendent Mather speaking to the toast of what he wants in 1897, and Mr. S. E. Thompson telling why he is kind to the ladies, we realize that harmonious influences are at work to make the operation of the road worthy of New Haven as the home of Yale University, and a model for other systems. As one of the men remarked, they would rather stand the sleet and snow beating in their faces, than some of the hard things said about them by the public in thoughtless criticism; and we opine that the public when it sees the whole force working together to give good service, and sensitive to praise or blame, will realize that every honest effort is being made to treat it well.

SUB TROLLEY FOR NEW YORK CITY.

THE development of the street railway situation in New York City is being followed with much interest, and is worthy of attention. It has been a kind of triangular fight, the Metropolitan Company wanting to run on certain lines by electricity, the people on Eighth avenue trying to force them to operate also on that thoroughfare, as well as on the Sixth avenue; and the Third Avenue Company trying to block the whole business by preventing the railway commission from granting its sanction. The Metropolitan Company has now wisely agreed to make its Eighth avenue sub-trolley line continuous, so that one of the sets of disputants is placated; and if the street railway companies would now only get together and "pool their issues," the whole thing could be settled without further trouble. Be that as it may, New York is certainly going to see a large and costly trial of the sub-trolley method. The argument that the open conduit is unhealthy has been disproved, although, of course, an open conduit is not as desirable as a closed one, and a cable conduit is less desirable than either. The stories about electrolysis due to sub-trolley or conduit systems are also such as hardly to need repetition. We must confess our wish that one of the lines could have a full equipment of the closed conduit method, so that its operation might be tested and watched as compared with the open type.

STREET RAILWAY ACCIDENT SUITS.

ONE of the lawyers of the street railway companies in Brooklyn said last week that the roads there had been distributing, in the unlitigated settlement of damage claims, more money than all the charitable institutions of the city put together. There certainly has seemed to be a terrible number of accident claims and cases, over the Bridge, and it is even said they form four-fifths of the entire litigation before the courts. On the Supreme Court calendar there are over 150 damage suits pending against the Nassau Electric road and over 200 against the Brooklyn Heights road. New cases enter upon their initial stages at the rate of thirty a month. But it may be questioned whether courts and juries will go on forever awarding large sums, and, while at one time the absence of many possible precautions did open the way to heavy mulcting, every time a company adds to its equipment that which shows it to be anxious for the safety of those in its cars or on foot in the streets, it gains an amount of public and moral approval that has a definite cash value when it has to meet charges of carelessness. To the old adage that "He is thrice armed who hath his quarrel just," may be added the comment that the company is most vulnerable that obviously makes no effort to insure itself by means of modern, scientific appliances.

The curious interrelation between the various branches of electricity has just been brought out by a case in Baltimore, in which a man asked $3,500 for injuries received by his arm while on a car. Rather than bother with a law suit, the company offered him $100 to compromise the claim. He refused to accept that, and the company therefore contrived to take a radiograph of the arm. The picture showed the bones to be intact, and when the bandages were removed the marks on the skin were found to have been made artificially with acid. The claimant thereupon offered to take $25, but the company is now waiting to be sued.

THE BUCKET SHOPS.

WITH reference to our editorial comment last week on the stock ticker situation, we now note that the N. Y. Stock Exchange has given notice to withdraw its quotations from the Gold & Stock Company, or, in other words, the Western Union Telegraph Company. The reason given is breach of contract of a flagrant character, but we fail to see how the company or any other company can meet the conditions which would require the quotations to be bottled up. Some of the courts may have decided that the quotations are the private property of the exchange; other courts do not think so, and it is obviously desirable that quotations should be given the greatest publicity.

If, as alleged, "express" quotations have been sent out to bucket shops by private wire, that is an offense which, when proved, can be punished with very severe penalties. It seems to us, putting the matter broadly, that it is the duty of the Western Union Company, as a common carrier, to treat all comers alike, and then the duty of the legal authorities to suppress the bucket shops or any other stock dealing institutions that are illegal.

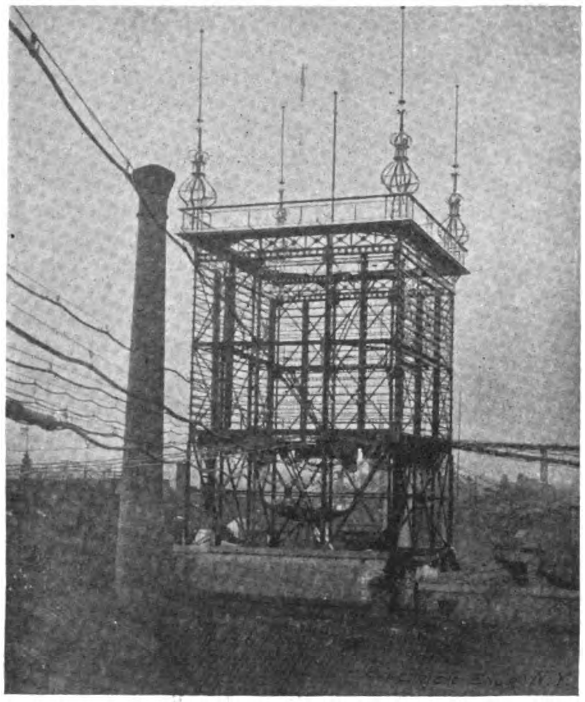
THE workhouse committee of a county in one of the Western States is very much enamored of a project to put in a small gasoline engine "with dynamo attachment," so that they can "generate enough current to light the house, pump water and saw wood." The price of the new apparatus is put at only $300, and the committee are the more favorably inclined toward the plant because "it is represented that it would cost only two cents per day to operate it." We recommend them to close at once with the offer, under a guarantee. They probably will never get anything better until the time comes when, as Dr. Lodge intimates, one man by just turning a crank may light a whole city. Many of the municipal plants, however, appear to be already on that economical basis.

THE Western Union Telegraph Company is, as we all know, a big, bloated, water-soaked, resistless monopoly that owns the earth, but once in a while it finds there are limits, and, like Charles the First, meets John Hampden. Out in Mason City, Iowa, a difference arose lately between the company and its local landlord. No agreement being reached, the haughty landlord pitched all the company's tables, furniture, instruments, etc., out into the street; and there doesn't seem to be anything for the helpless, hundred-million-dollar company to do but pick up its goods and chattels and find another lodging with a more placable owner. It is now whispered that the landlord does not favor prohibition.

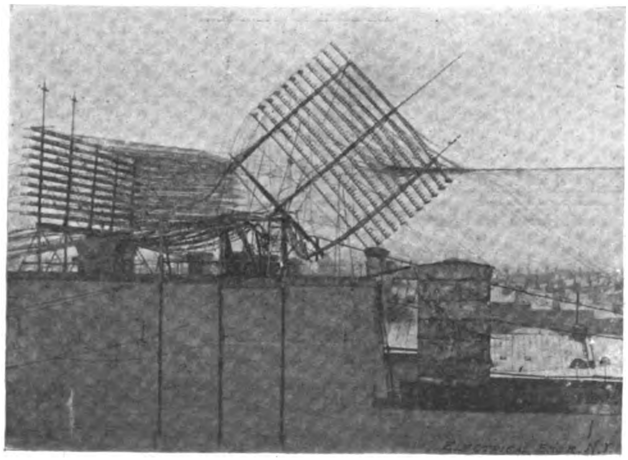
TELEPHONY AND TELEGRAPHY

HAVOC AMONGST OVERHEAD TELEPHONE LINES AT STOCKHOLM, SWEDEN.

One of the most notable and talked-about exchange systems in Europe is that of the General Telephone Company, at Stockholm, Sweden. The rates are low, the number of subscribers is large, and the results appear to have been quite satisfactory, due in large measure to the energy and ability of Mr. H. T. Cedargreen, the managing director, who is well known to many American telephonists. But while this exchange has often been held up as a general all-round model for American imitation, there would appear to be some shadows in the picture, and information recently received in this country would go to show that the low rates carry with them the dangers of a cheap service. It appears that a storm swept over the city of Stockholm, with snow and wind, early in January. In less than an hour 3,000 lines were thrown out of service. The big tower fixture on the central exchange shown in one of our illus trations lost 1,377 of its lines in the storm's "fell swoop." A curious condition of wreckage of another large fixture is also shown, while in a third view a startling scene of damage is presented. The leverage of the wind, acting against the fixture and wires, actually lifted the roof of a large apartment house several feet from the walls of the building and the weight being thrown over on one side, crushed that in; whilst the roof on the near side is held up like a huge eyelid that could not be closed.

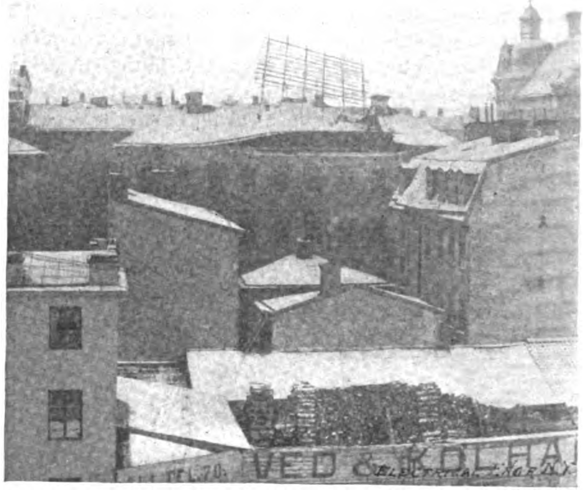


Telephone Tower, Stockholm, Sweden.



Wrecked Telephone Roof Fixtures, Stockholm, Sweden.

The effects of the storm extended also for some miles around the city, and other photographs show pole lines down in every direction. The net result was that it took six weeks to repair the damage, and that for a great many of the subscribers telephone service during that long time existed only in name. The repairs have also been extremely costly, and the company is now confronted with the problem of the large expense of going under ground. The pleasant superstition that all the telephone wires in Europe are underground is gently dissipated by such incidents as this, and it is certain that no city of 275,000 inhabitants in the United States is so far behind as Stockholm in placing its telephone wires out of sight; or, if having them still in sight, could not get its service into condition again after disaster in much less than six weeks. But the problem confronting the General Telephone Company of Stockholm is its low rates, which do not permit the large new investment necessary to guard against such serious interruptions in the future, and which would have to be considerably advanced to make the outlay fairly remunerative.



Roof Lifted by Broken Telephone Fixture, Stockholm, Sweden.

SALE OF THE INDEPENDENT TELEPHONE SYSTEM IN ROCKLAND COUNTY, N. Y.

An interesting little chapter of contemporaneous telephone history is disclosed by the announcement of the sale of the "independent" Rockland Telephone and Telegraph Company, of this State, to the New York Telephone Company (Bell system). The argument that the low rates so often quoted for good service are not possible finds its proof again in this instance, while some of the other factors in the situation cannot be overlooked. The Rockland Company, operating in a large and prosperous section of the State, has been in existence three or four years and has done excellent work, but Mr. W. H. Russell, its treasurer, states that its rates of $2 and $3 per month were too low. It had its principal exchange at Nyack on the Hudson, and three branch exchanges at other points in the county, and its list of subscribers varied from 60 to 75, there being 63 at the time of the sale. It had about 18 to 20 miles of pole line, excellently built by a man who was familiar with telephone line construction, and its service was well kept up. The subscribers were bunched two or three on a line, and were well taken care of, but the main trouble seems to have been the inability to get connection outside the county, with New York City and other places with which it was desirable to have communication. There were no "independent" companies with which to exchange business, and the company was thus cooped up, to feed on its own vitals. Many of the subscribers, to whom this "extra territorial" connection was a necessity, had to keep the Bell service in their places of business and were thus under a double expense, although their chief reason for patronizing the Bell system was to have ready access to the facilities of the long-distance service, both up and down the Hudson, reaching now no fewer than 32,000 telephone subscribers in this territory alone.

The Rockland Company, finding that it was steadily losing money and patronage, opened negotiations with the New York Telephone Company, and has now sold out at a price which shows a serious loss on the original cash investment. The company had no watered stock, and was carefully run, but conditions and low rates were too much for it. In taking possession, the New York Telephone Company has stated that it will make no advance on its present rates for telephone subscribers in exchanges of similar size, but will charge only from $30 to $50 a year for its service. The toll charge from Nyack to New York City is 35 cents, and there would appear to be considerable business to be transacted in view of the fact that Rockland County furnishes the city with a large quantity of its purest natural ice.

TELEGRAPH CODE FOR DEAF-MUTES.

A Texas doctor thinks it is time what he terms "the crazy-looking gesticulations" of the old deaf-and-dumb system should be discarded, and a clearer and more intelligent method introduced. He proposes that in all deaf-and-dumb institutions the training and education of the scholars shall be based on telegraphic system, without the voice, and, in a great measure, without gesticulation. As a first step the pupil is to familiarize himself with the symbols of the ordinary telegraph code. Instead of instruments, however, he will use, in giving the indicating signs, certain movements of the lips and mouth and the index finger. In telegraphy there are but three symbols—a dot and two dashes of different lengths, or a small dash and two long ones. Communications in any civilized language can be expressed by a combination of these symbols. In the suggested system a pucker of the lips would express a dot, and a separation of the lips to the required degree would indicate the dashes. At each end of a word a slight movement of the right hand or right index finger is given; at the end of each sentence a touch of the lips with the index finger. "Yes" is implied by a nod, "no" by a shake of the head, and "I don't understand you" by a blink of the eyes, etc. The preliminary training on this system is first to give object lessons, so as to convey the true meaning of each word. After the pupil has made some progress a grammatical construction of the language can be ventured upon. The author of the system contends that in this way a pupil can be educated to a high standard much more quickly than under the old method. He believes it would not take long to make the system even graceful. This practice of the muscles of the face would not interfere with or mar the expression of the emotions. A smile or a frown would retain its natural meaning. A communication could be given without attracting special attention, and the infirmity of the subject could often be concealed. The system would virtually give speech to the lips of the deaf and dumb. —Boston Transcript.

THE TELEPHONE WAR IN MICHIGAN.

A dispatch from Grand Rapids March 6 says: The telephone war is waxing hot in this State, and it will be carried to an extermination either of the new independent companies or that of the old Bell company. In this city the new company has over 100 subscribers, while the Bell, which long monopolized the telephone business, has been reduced to about 900, and it gives free service to all residents. A new exchange has just been opened in Detroit with 1,500 subscribers, which will be increased to 3,000 before May 1, and the same conditions exist in other cities in the State. A company has been organized with William L. Holmes of Detroit as president, to connect all the independent exchanges for a State service, and this work is being rapidly pushed. Wires radiate from this city to Lansing, Muskegon, Holland, Ionia and Hastings, and a line is being pushed north as rapidly as possible to Traverse City and Petoskey.

In Detroit lines are being extended to all points within a radius of twenty-five miles, and a State line is being built eastward to Jackson and Kalamazoo, and also to Lansing, to connect with the line to this city.

The Bell company already has lines from this city to Detroit and to many other points in the State, and is paralleling the new line northward to Petoskey, with Mackinaw as the objective point.

In all the towns where independent exchanges have been established rates have been cut, and as rapidly as the State lines are ready for business the State rates tumble from 25 to 50 per cent. The war will be particularly fierce this summer.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—II.

MODERN TYPES OF CELLS OF AMERICAN, ENGLISH, FRENCH AND GERMAN MANUFACTURERE.

BY JOSEPH APPLETON.

(*Copyright*, 1897.

DURING the past ten or twelve years there have been a great many storage batteries invented and put on the market, most of them being introduced with much enthusiasm, their inventors, or sponsors, claiming wonderful and often impossible results. Nearly all these cells have been manufactured under one or other of the two general methods described in the previous article, the majority of them being alike except in detail of construction and manufacture. As our object is to treat of modern storage battery practice, we shall only consider generally those types which have played the principal part in the industry and have attained some degree of commercial success.

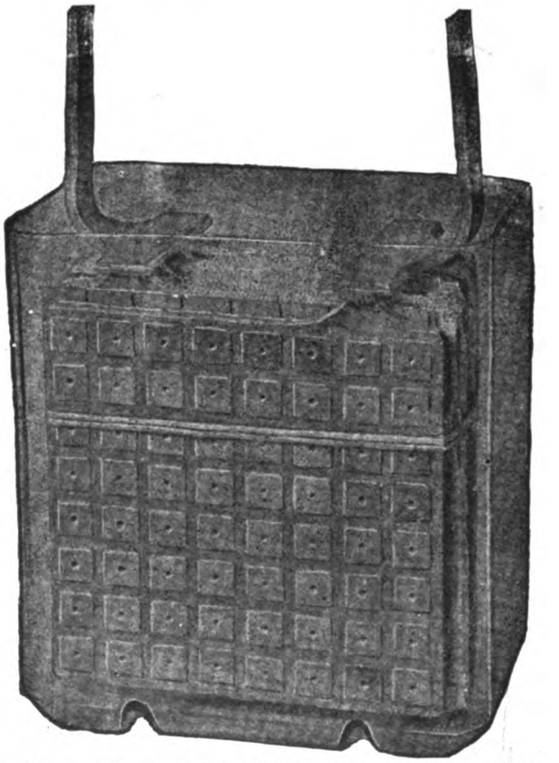


FIG. 1.—TYPE "E", 9 PLATES, IN GLASS JAR. ELECTRIC STORAGE BATTERY CO.

For a long time the charge and discharge rate of a cell was fixed at ten hours; this was called the "normal rate," and meant that the cell must not be discharged in less than ten hours, and that the same time must be allowed for charging. This necessarily restricted the use of storage batteries, for if a large current was wanted from them, even for a short period, it required the battery to have a normal rate equal to the maximum discharge wanted. This necessitated a very large battery and consequently a too expensive one to be commercially practical.

This was especially the case in central station and railway work, where large currents are required for comparatively short periods of time. Storage battery manufacturers realized that if a cell could be made which would stand this class of work without sacrificing durability, it would open up a very large field for their apparatus, and it is in this direction that the chief improvements have been made during the last few years.

Modern practice calls for a cell which can be safely discharged in from one to three hours, the former rate being generally specified for central station work, with the capability of a much higher discharge rate for a few minutes. The rate of charge is generally limited to five hours. It will readily be seen that this rating increases the value of a storage battery from the engineer's point of view, and at the same time decreases the cost per kilowatt. The present cost of storage batteries for central station and similar work is less per kilowatt than that of modern generating machinery.

The principal manufacturer of storage batteries in America is the Electric Storage Battery Company, of Philadelphia. Besides this company there are several others which manufacture various types of storage cell among them being the Electro-Chemical Storage Battery Company, of New York; the American Battery Company, of Chicago, and the Willard Electric and Battery Company, of Cleveland.

In England there are the following companies: The Electrical Power Storage Company, which was one of the earliest in the field, which has always controlled there the patents under which the pasted type of plate is made, their principal patents having, however, recently expired; also the Chloride Electrical Storage Syndicate, the D. P. Accumulator Company, the Crompton-Howell and Epstein Companies. In France the Société Anonyme pour le Travail Electrique des Metaux, manufacturing under the French patents of the Chloride Electrical Syndicate of England and the Electric Storage Battery Company, of America.

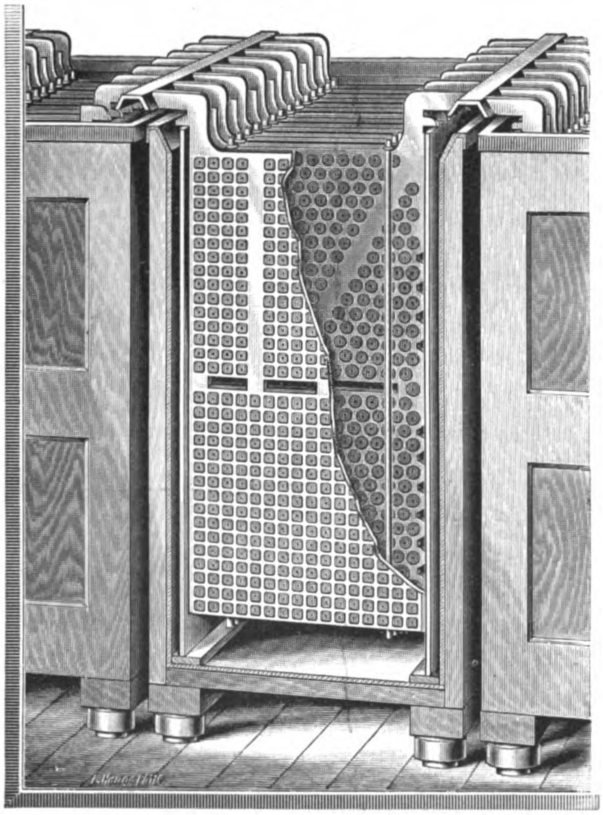

Fig. 2.—Central Station Cell. Electric Storage Battery Co.

In Germany, the Tudor Company is the principal manufacturer, working under license from the Electrical Power Storage Company, of England, and patents of their own. Germany may really be called the home of the practical storage battery, as the Tudor Company was the first to demonstrate its value for central stations and similar work of extensive character.

There is no doubt that the storage battery industry, both from the manufacturers' and users' point of view, is now on a better basis in America than in any other country.

This may appear strange after the condition of affairs which formerly existed, yet when the real facts are carefully examined it is apparent that this country offers a greater field for the use of storage batteries than any in Europe, and consequently as soon as a reliable battery was available without the prospect of an accompanying law suit, American energy set about to fill the demand.

The manufacture of storage batteries to-day is not confined to the production of one type of cell, but includes as many types as there are conditions of service. For example, it is obvious that for central station and power work, where a battery is wanted which will stand up under excessive discharges for short periods, and which can be charged economically in a short time, the type of cell must needs be different from that used in isolated plants, where large capacity and comparatively slow discharge rates are required. Again for storage battery traction and motor vehicles, a battery of light weight with large capacity is needed, durability not being such a desideratum.

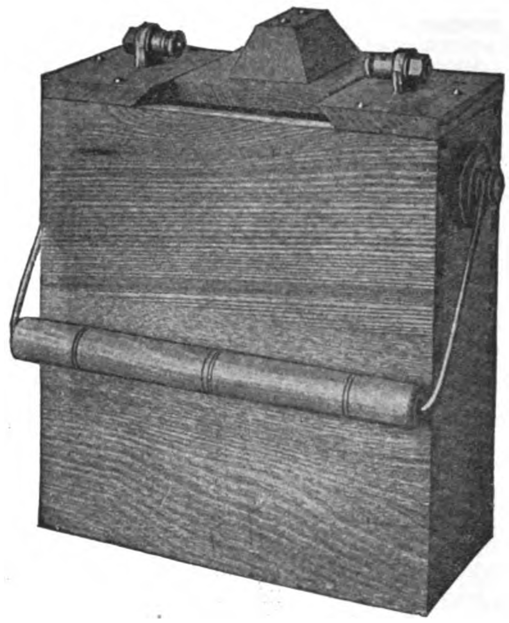

Fig. 3.—Portable Cell. Electric Storage Battery Co.

It would be impossible to give in these articles complete tables and data of all the cells manufactured by the various makers; a brief description of the size and different types must suffice.

The Electric Storage Battery Company of America are probably better equipped than any other company in the world to supply the demands for various types of storage batteries. This company manufactures cells for all purposes and of all sizes, the capacity ranging from 5 ampere hours up to 20.000 amperes. The smaller sizes, up to about 500 ampere hours are furnished in glass jars, and for portable use in hard rubber boxes, while the large sizes are supplied in lead-lined wooden tanks.

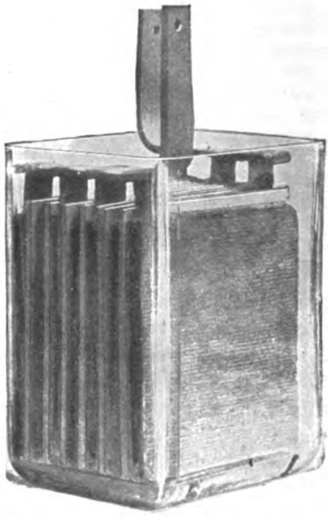

Fig. 4.—Electro-Chemical Storage Co.'s Cell.

Fig. 1 shows a cell of their standard type "E" 9, in glass jar, suitable for general lighting work, with the plates joined respectively to lead straps which form the + and — poles of the cell. The capacity of this cell is 160 ampere hours, having the following discharge rates: 20 amperes for 8 hours, 28 amperes for 5 hours, 40 amperes for 3 hours, 80 amperes for 1 hour. Fig. 2 illustrates one of the larger central station type of cells in lead-lined wooden tank, containing 15 "H" plates, having a capacity of 2,240 ampere hours, with the following discharge rates: 280 amperes for 8 hours, 392 amperes for 5 hours, 560 amperes for 3 hours, 1,120 amperes for 1 hour.

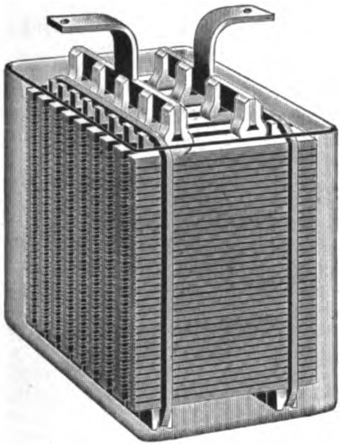

Fig. 5.—American Battery Co.'s Cell.

This type of cell is made up to 20,000 ampere hours capacity, having a maximum discharge rate for one hour of 10,000 amperes. The plates are supported on sheets of glass, resting on the bottom of the tanks and are connected to lead bus bars, the joints being made with a weld effected by means of a hydrogen flame, the only process which will ensure a clean and perfect contact. This method will be fully described later on.

Fig. 3 illustrates the portable type of cell; here the plates are mounted in a hard rubber-containing jar, which in turn is placed in a hard wood box to prevent accident from breakage and to render it easily handled. The cells are covered with a lid secured by a sealing compound, allowing the necessary ventilation, but preventing the spilling of the electrolyte. These cells are made with capacities ranging from 10 to 200 ampere hours, and comprising one to five cells in each box giving 2 to 10 volts, according to the number of cells. They are used for supplying current to phonographs, kinetoscopes, carriage lamps and for similar purposes.

Fig. 4 illustrates a cell manufactured by the Electro-Chemical Storage Battery Company, of New York. It is of the Planté type, the plates consisting of grids having grooves on both sides, to give large surface area.

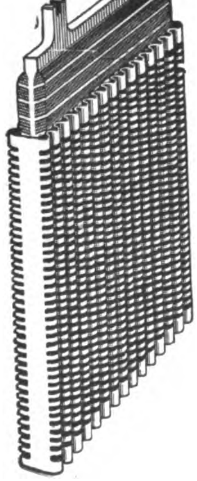

Fig. 6.—Willard Storage Battery Plate.

Fig. 5 shows a cell manufactured by the American Battery Company, of Chicago, type N 4, in glass jar; its capacity is 180 ampere hours with discharge rates as follows: Slow rate, 14 amperes; normal rate, 20 amperes; high rate, 40 amperes. The special features of this cell are large surface area due to the special construction of the plates which are made from pure rolled lead grooved on both sides.

Fig. 6 illustrates a plate of the Willard type, manufactued by the Willard Electric and Battery Company, of Cleveland.

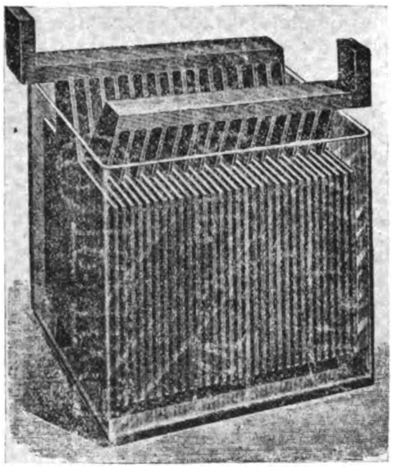

Fig. 7.—The Faure-King Cell.

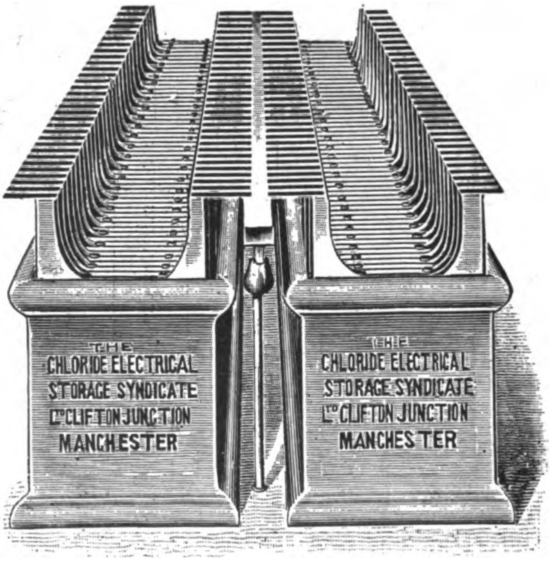
The Electrical Power Storage Company, of England, adhere to the pasted type of plate which has always been the chief feature of their work, and have recently introduced a new cell called the Faure-King type. This cell is illustrated in Fig. 7. The chief advantages claimed for this type are increased capacity and discharge rates, for the same surface area of plates as compared with their older types.

This cell is very light and can be discharged at very high rates for short periods. The illustration shows a cell of the lighting type having 31 plates mounted in glass jar, their capacity being 1,300 ampere hours with discharge rates as follows: 145 amperes for 9 hours; 295 amperes for 3½ hours, with capability of higher rates for short periods. This cell is also manufactured for central station and traction work, a special design of cell being made for auto-cars and motor vehicles.

The Chloride Electrical Storage Syndicate, of England, manufacture a large variety of cells. Fig. 8 shows their central station type of cell in lead box. These cells can be discharged at high rates without injury.

The D. P. Accumulator Company of England manufacture cells of the Planté type, which have met with great success in private installations and similar work, durability being one of their principal features. Fig. 9 shows this type of cell.



THE CHLORIDE ELECTRICAL STORAGE SYNDICATE LTD CLIFTON JUNCTION MANCHESTER
THE CHLORIDE ELECTRICAL STORAGE SYNDICATE LTD CLIFTON JUNCTION MANCHESTER

Fig. 8.—Manchester Chloride Cell.

The Tudor Company of Germany classify their cells in the following manner: 3 to 10 hour discharge rates and 1 to 3 hour discharge rates. The range of capacity is very large, extending from 30 ampere hours up to 12,000 ampere hours.

Fig. 10 illustrates one of their central station types. In this class of cell the positive plates are built up of small sections about six inches square, mounted in a lead or alloy frame; the sections being attached to the frame by a lug at the top. This method enables a positive plate of large size to be constructed without the liability to buckling which occurs in all large plates of this description which are made in one piece. This company is equipped for the manufacture of both pasted and Planté types of plate, using the one best suited to the requirements. As previously stated, this company was the pioneer for storage battery installations in central stations, and the first plants of this character in America were carried out by them. These will be described and ilustrated later.

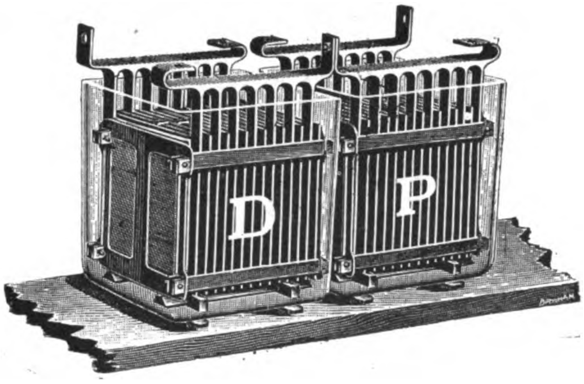


FIG. 9.—ENGLISH D. P. CELL.

The storage battery of to-day is a practical and mechanical piece of apparatus. Engineers have come to the assistance of the chemist, the result being a well designed and constructed apparatus, free from the weak points which were inherent in all early types of cells, and which necessitated the constant attention of a skilled doctor or nurse. This fact alone has done much to create confidence in the minds of electrical engineers, and to wipe out the memory of the early and disastrous results.

Every one who had any connection with storage batteries, in former years, will remember the trouble caused by buckled plates, insufficient separation, unreliable and corroded connections, and general debility of the apparatus. The writer well remembers bringing over from England to this country, in 1886, a new cell which was expected to do wonders, and, in fact, was a remarkable cell in many ways, but was constructed in such a fragile manner that he was compelled to keep the plates wrapped up carefully in soft packing, never letting them go out of his sight, and watching them in his cabin during rough weather for fear they might not stand the knocking about which any ordinary piece of baggage would stand with impunity.

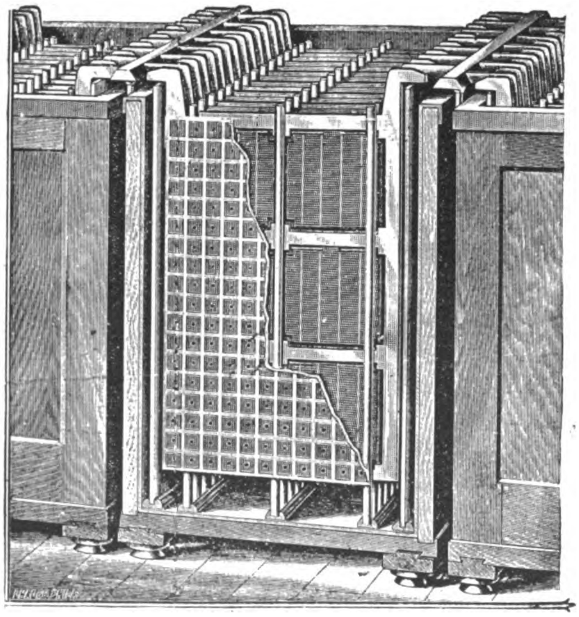

FIG. 10.—GERMAN TUDOR CELL, CENTRAL STATION TYPE.

This is now a thing of the past. The storage battery of to-day, being well able to take its place alongside of other modern and improved machinery, compares most favorably with the same as regards cost of operation and maintenance. On this point we may quote the following remarks from a communication read before the American Institute of Electrical Engineers on Nov. 20, 1895, by Mr. C. L. Edgar, vice-president and general manager of the Edison Electric Illuminating Co., of Boston, who were the pioneers in this country in the use of storage batteries on a large scale in central stations, having had them in operation since April, 1894.

"Having satisfied ourselves in the beginning that with a given amount of capital we could do more work with the battery than without it, we by actual practice came to the conclusion that we could by the same means do this same amount of work more cheaply.

"The fixed charges of running a battery room are very small as compared with those of a steam station, and there would not be any material increase of fixed expense between one large battery located in a central point, and half a dozen small ones distributed throughout the city.

"Our company has used the first battery 20 months, and one of double its capacity for six months, entirely too short a time to come to any conclusions about the depreciation, but it has given us ample time to satisfy ourselves as to the economic value. It is sufficient for me to say that if a need should arise to-morrow for additional capacity, either at our main station, at either of the annexes or in any new part of the city, within reasonable distance of our center of distribution, we should consider the question along the lines which I have just indicated. We should eliminate entirely from the discussion, the question which has distracted the public mind for so many years, and decide it entirely upon its merits, placing the battery side by side, and on an equality with other modern and improved apparatus."

About one year after expressing the above opinion, the Boston Edison Company installed a third battery in an annex station for the purpose of opening up a new district.

PERSONAL

WILLARD E. CASE.

Willard E. Case.

So much attention has been drawn to the thermo-electric work of Mr. Willard E. Case that a brief biographical sketch of that gentleman will be interesting to many of our readers. He was born at Auburn, N. Y., in 1857, educated in public schools and by private tutors, graduated from Hamilton College Law School about 1880, and was admitted to the practice of law in this State. His tastes ran strongly, however, in the direction of physical study and research, particularly in the domain of electricity, and he very soon began to devote his energies wholly to the work of that character. He was not long in reaching results of a striking nature, and in 1886 he read a paper before the Royal Society in London on a new means of converting heat energy into mechanical energy, demonstrated by a battery of his own invention. Among other papers was one read before the American Institute of Electrical Engineers in 1887, which also attracted much notice, and is to be found in the Transactions, on a new form of carbon consuming battery. His paper read recently at Columbia University before the New York Electrical Society showed that his mind and work are still directed in pursuit of the solution of the same problem, and has been noted in a great many papers and periodicals in all parts of the country.

Mr. Case has had all the advantages that come from the enjoyment of large wealth, and is a good type of the men not so common here as in Europe who devote a large part of their means and leisure to scientific investigations, which may lead on to practical results, but, in any event, is followed up for its own sake. Mr. Case is a citizen of Auburn, though spending much time in New York or in Europe. He has just given, in memory of his father, the late Theodore P. Case, a Public Library Building to the city of Auburn, and has also created a fund to establish a Scientific Library in the building. Mr. Case is a member of the American Institute of Electrical Engineers.

FRED J. CROSS.

THE subject of this biographical sketch, Mr. Fred J. Cross, is the manager of the electrical department of the Buffalo Engine Works, Buffalo, N. Y. He is a Polytechnic School graduate, and has been in the electrical field since 1885. He has made a specialty of the design of electrical apparatus since 1891, and has several patents. At the present time, no fewer than three factories in Canada are building from his designs, and reference has already been made elsewhere in these pages to his work in this country. He is thus not only well informed theoretically but competent practically. Mr. Cross is also a frequent lecturer on electrical and other engineering topics, and is only 32 years of age.

Fred. J. Cross.

A FERRARIS MEMORIAL.

A committee has been organized under the presidency of Senator Count Rignon, mayor of Turin, Italy, to erect a fitting memorial to the late Senator, Prof. Galileo-Ferraris. It is proposed to erect the memorial in the Royal Industrial Museum of Turin, and to make the subscription an international one. Contributions can be forwarded to this office or direct to Sig. Cav. Lappata, treasurer of the city of Turin, Italy.

MR. W. F. WELLS.

Walter F. Wells, assistant superintendent of the Brooklyn Edison Electric Lighting Company, was the guest of honor on Wednesday night, March 10, at a dinner given at the Clarendon Hotel, that city, by a number of his fellow workers. Mr. Wells will leave the Edison company on April 1, having accepted the position of superintendent of the Manhattan Electric Lighting Company of New York. The dinner was in the form of a parting testimonial and assumed a very material character when Ethan Allen Doty, president of the Edison company, presented Mr. Wells with a handsome diamond stud. After the dinner the party saw "The Girl From Paris" at the Herald Square Theater. The party was composed of Ethan Allen Doty, R. C. Peabody, W. W. Freeman, A. N. Nielsen, W. F. Wells, Charles F. Perry, John F. Outwater, John Wolff, C. V. Driggs, John Flint, R. S. White, Theo. Guillaudeu, William J. Reast.

MR. W. J. KURTZ IN LUCK.

A special dispatch of March 10 from Indianapolis says: William J. Kurtz, president of the Kurtz Telephone Company, operating telepone exchanges at Decatur, Ill., New Albany, this State, and other points, besides seeking franchises for exchanges in a number of Indiana towns, has received notice that by the death of Gottlieb Kurtz, a bachelor uncle of Stuttgart, Germany, he will receive several million dollars, he being the sole heir. Mr. Kurtz is already wealthy. He will send a representative to Germany to look after his interests.

DR. HENRY MORTON, the veteran president of Stevens Institute of Technology, has been nominated by the trustees of Princeton University for the degree of L.L. D. The degree will be conferred next June. The other gentlemen thus distinguished are Rev. Dr. Theodore L. Cuyler, ex-President Cleveland, Governor General the Earl of Aberdeen, and the Hon. John L. Cadwalader, who are in good company.

THE STOCK MARKET

A SLOWLY RISING MARKET.

With Congress and Crete out of the way, it is evident that general conditions would be much better than they are, as the tendency to improve slowly is quite marked, while the tendency to get nervous and rattled is still one of the besetting weaknesses of the investor and merchant.

Under the strain of uncertainty the stock market continues dull, neither strong nor weak, in an alternating mood at best. Western Union has been slightly lower, probably because the deprivation of the stock exchange quotations for the tickers would deprive it of a source of large and profitable business. During the past week there were sold 23,404 shares down to 83¾, after reaching 86½. General Electric on 7,102 shares ranged from 35⅝ to 34⅜. The price for American Bell Telephone went off one dollar to 223, but the sales were only 287 shares. The chief event in local company securities is the offering of $6,000,000 of bonds of the West Chicago Street Railway Company, at 5 per cent.

SOCIETY & CLUB NOTES

AMERICAN INST. ELEC. ENGINEERS.

At the meeting of the Institute to be held March 24, at 12 West Thirty-first street, New York City, at 8 P. M., a paper by Dr. Karl E. Guthe will be read by Prof. H. S. Carhart, of the University of Michigan, entitled: "The Influence of Heat Treatment Upon the Magnetic Properties of Hardened Steel."

N. E. L. A. CONVENTION.

Mr. C. O. BAKER, Jr., master of transportation, announces that the trunk line association have granted a rate of fare and one-third, for the round trip, on the certificate plan, from all points in its territory to Niagara Falls, for delegates and members of the National Electric Light Association attending the twentieth convention to be held June 8, 9, 10, 1897.

LEGAL NOTES

WESTERN ELEC. CO. vs DOLGEVILLE TELEPHONE CO. JUDGMENT ENTERED.

In the case of the Western Electric Company against the Dolgeville Telephone Company judgment has been entered in the office of Clerk Doolittle, of the United States Court, at Utica, N. Y., of one cent nominal damages and costs against the defendant. The costs were taxed at $243.34. E. A. Brown, of Dolgeville, was attorney for the defendant, and C. A. Brown, of Chicago, for the plaintiff. The action was begun in April, 1895, for infringement of patents on switchboard, or exchange apparatus, used by the Dolgeville Company. It was set down for trial at the term in Albany last January, but no one appeared for the defendant, and a decree was entered in favor of the plaintiff. At Judge Coxe's Special Term on February 16 a motion by defendant's counsel to vacate that decree was granted on condition that defendant pay $150 within twenty days to defray the expenses of plaintiff's counsel. The payment was not made, and the matter was brought to an end by the entry of judgment as above stated. The decree also enjoins the plaintiff from using the exchange apparatus in question during the life of the patents, which are declared valid. Theodore H. Roth is president, and W. S. Armstrong secretary and treasurer of the Dolgeville Company.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 16, 1897.

Alarms and Signals:—

ELECTRIC CALL AND CALL ANSWERING APPARATUS. E. H. Owen, C. N. Williams and F. H. Donaldson, Garvanza, Cal., 597,075. Filed Sept. 14, 1896.

Possesses a plurality of visual-signal devices susceptible of being independently operated when an electric circuit is completed by operating a push button.

BURGLAR ALARM. M. P. McDermott, Auckland, New Zealand, 578,893. Filed Aug. 7, 1896.

The movement of a door, window, etc., completes a circuit.

WATER INDICATOR AND ALARM. G. W. Cooley & H. F. Logee, Minneapolis, Minn., 578,725. Filed August 15, 1895.

Details of construction.

Batteries:—

ELECTRIC BATTERY. H. N. Farley, Warwick, N. Y., 578,867. Filed April 11, 1895.

A single cell "gravity" battery having the elements so disposed as to produce a plurality of currents.

Batteries, Secondary:

BATTERY. S. J. Martin, Detroit, Mich., 579,001. Filed May 27, 1896.

In a secondary battery, an electrode, consisting of a series of perforated tubes attached to and surrounding a central core, the tubes adapted to contain the active material.

PASTE FOR ELECTRIC ACCUMULATORS. R. Linde, Berlin, Germany, 578,881. Filed Feb. 24, 1896.

A filling paste for electric accumulators in which the lead oxids are contained combined with a bitter principle.

ACTIVE MASS FOR ELECTRIC ACCUMULATORS. S. Hammacher, Berlin, Germany, 578,870. Filed June 27, 1895.

Consists of basic phenylates of lead mixed with the oxids of lead.

CHARGING SECONDARY BATTERIES. I. Kitsee, Philadelphia, Pa., 578,823. Filed Nov. 2, 1895.

Employs a number of incandescent lamps connected in series, each pole of each lamp being connected to a conducting plate adapted to receive the terminal of one pole of a battery set.

STORAGE BATTERY. C. T. Barrett, Brooklyn, N. Y., 578,710. Filed May 4, 1896.

A cell, consisting of a plate of pumice stone, to which the peroxid material is applied in combination with a confining envelope of lead, having openings for the admission of the acidulated fluid.

Connectors, Conduits and Insulators:—

INSULATOR. H. H. Luscomb, Hartford, Conn., and W. F. D. Crane, Orange, N. J., 578,825. Filed Oct. 24, 1896.

Consists of a body provided with means for attachment to a support and having arms that project upwardly from opposite sides of the body near the top, fingers loosely connected with and movable between the arms, a part of the fingers being adapted to support the wire and a part of the fingers being caused to embrace the wire by the action of the weight of the wire.

Dynamos and Motors:—

ELECTRIC MOTOR AND DYNAMO. W. S. Horry, Gloucester City, N. J., 579,062. Filed June 15, 1892.

Comprises means for producing rotating field poles, means for producing rotating armature poles in the same direction and speed as the field poles, and rotating the armature in one direction for energizing the field and armature coils, and means for controlling the speed of rotation and reversing the direction of the field of force.

CONSTRUCTION AND REGULATION OF ELECTRIC MACHINES. T. H. Hicks, Detroit, Mich., 579,059. Filed Feb. 23, 1895.

Means to prevent sparking.

DYNAMO ELECTRIC MACHINE. G. A. Scheeffer, Peoria, Ill., 579,012. Filed April 30, 1892.

Of the inductor type.

Electro-Metallurgy:—

TANK FOR TREATING ALLOYS, ETC. F. A. Thum, Newark, N. J., 578,953. Filed June 25, 1896.

Comprises an electrolytic tank anode cells with permeable bottoms; carriages constructed to support the anode cells when immersed into the tank and adapted to be moved horizontally; one or more cathodes placed upon the bottom of the tank, and suitable electric connections for the electrodes.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. T. E. Adams, Cleveland, Ohio, 579,032. Filed Oct. 1, 1896.

Enclosed arc lamp.

Measurement:

ELECTRICITY METER. A. Raps, Berlin, Germany, 579,079. Filed July 25, 1896.

Consists of a suitable direct reading electrical measuring instrument, an oscillating balance and a registering wheel.

Miscellaneous:—

MEANS FOR PROTECTING ELECTRIC MACHINES FROM HEAT. J. P. B. Fiske, Alliance, Ohio, 579,051. Filed Jan. 12, 1895.

Employs a housing enclosing the machine, the former having openings in the ends, a fan located in one of the openings being carried by the armature shaft of the electric machine.

ELECTRIC ELEVATOR. S. D. Strohm, Philadelphia, Pa., 579,024. Filed April 4, 1896.

The opening of a landing door breaks the circuit, stopping the car.

TEMPERATURE CONTROLLING APPARATUS. S. Green, New York, 578,984. Filed June 16, 1896.

Relates to thermostatic regulation of temperature of buildings heated.

ELECTRIC CLOCK-SETTING EMCHANISM. C. M. Crook, Elgin, Ill., 578,976. Filed January 11, 1897.

Details of construction.

TELEGRAPH FIRE HOSE. J. Buchtel, Portland, Ore., 578,716. Filed April 14, 1896.

Provides a telegraph hose adapted for use in connection with a central controlling station and signal apparatus, so that by means of the signal the operator at the controlling station can cut the water on or off.

ELECTRIC CARRIER APPARATUS. H. M. Neer, Springfield, O., 578,939. Filed July 25, 1896.

Package and change system for store.

Railways and Appliances:—

ARRANGEMENT FOR CLOSING OR OPENING BARS AT RAILROAD CROSSINGS. H. Biermann, Breslau, Germany, 578,853. Filed April 6, 1896.

Comprises a rail in three insulated sections, an alarm connected to the outside sections, and an electric motor controlling the gate connected to the central station.

RAILWAY CROSSING SIGNAL. C. Selden, Baltimore, Md,. 578,840. Filed February 11, 1897.

Designed for single track railroads and adapted to be operated by an approaching train.

RAIL BOND FOR ELECTRIC RAILWAYS. T. J. Tighe, Brooklyn, N. Y., and S. W. Childs, Natick, Mass., 578,829. Filed October 9, 1896.

Consists of two metallic conductors, one on each side of the rail, and having inwardly projecting ends and means for drawing the ends into a single hole in the rail securing them.

Regulations:

REGULATOR FOR ELECTRIC MOTORS. R. M. Hunter, Philadelphia, Pa., 579,063. Filed May 22, 1894.

Comprises an electric circuit and power motor arranged in the circuit, and a counter electro-motive force regulator wholly independent of the field of the power motor and arranged in a shunt circuit about the entire power motor.

CONTROLLER FOR DYNAMO ELECTRIC MACHINES. C. E. Woods, Chicago, Ill., 579,028. Filed January 15, 1896.

Designed for use in connection with power motors. Details of construction.

ELECTRICAL CONTROLLING APPARATUS. B. C. Van Emon, San Francisco, Cal., 578,954. Filed May 22, 1896.

Comprises a reversible motor and a triple reversing armature circuit switch, mounted and turning on a axis, solenoids to move the switch either way and reverse the motor.

CONTROLLING MECHANISM FOR ELECTRIC MOTORS. F. R. Bacon, Milwaukee, Wis., 578,707. Filed December 21, 1896.

Details of construction.

Switches, Cut-Outs, Etc.:—

LIGHTNING ARRESTER. W. K. Freeman, Fort Wayne, Ind., 578,981. Filed July 5, 1895.

For use on lines carrying heavy currents.

CIRCUIT BREAKER. H. P. Kelly, Philadelphia, Pa., 578,150. Filed April 7, 1893.

Employs a breakable strip included in the circuit, and mechanical means controlled by the circuit for mechanically breaking the strip without previously fusing it.

Telegraphs:—

REPEATER. C. W. Leiser, Carlinville, Ill., 578,997. Filed April 1, 1896.

Comprises two relays provided with armature levers, each having two spring contacts, two stationary contact points for each armature lever, two batteries connected with the main lines and with the forward stationary contacts of the relays, and the electrical connections, whereby signals made on one line will be repeated on the other.

Telephones:—

TELEPHONE-SWITCHBOARD PLUG. F. E. Bossong, Watseka, Ill., 579,036. Filed September 16, 1896.

The same plug is used to receive the called number and to ring up the desired subscriber.

TELEPHONE TRANSMITTER. W. J. Moore, Elmer, Mich., 579,003. Filed May 25, 1896.

Relates to the "cup" part of the transmitter.

MULTIPLEX TELEPHONY. S. W. Holman, Boston, Mass., 578,992. Filed May 31, 1893.

Employs at each end a telephone, each terminal of which is connected in multiple with the two conductors of one original circuit through the two windings of a differentially wound electro-magnetic coil.

CUT-OUT AND AGITATOR FOR DUST TRANSMITTERS FOR TELEPHONES. S. B. Rawson, Elyria, O., 578,771. Filed June 14, 1895.

Consists of a dust transmitter on a joined arm, a battery wire connected to the arm and movable therewith, the bell connections having fingers in position to be engaged and thrown into circuit by the arm in one position, and the transmitter having a finger connected to the battery circuit and in position to be engaged by the arm when in another position.

OBITUARY

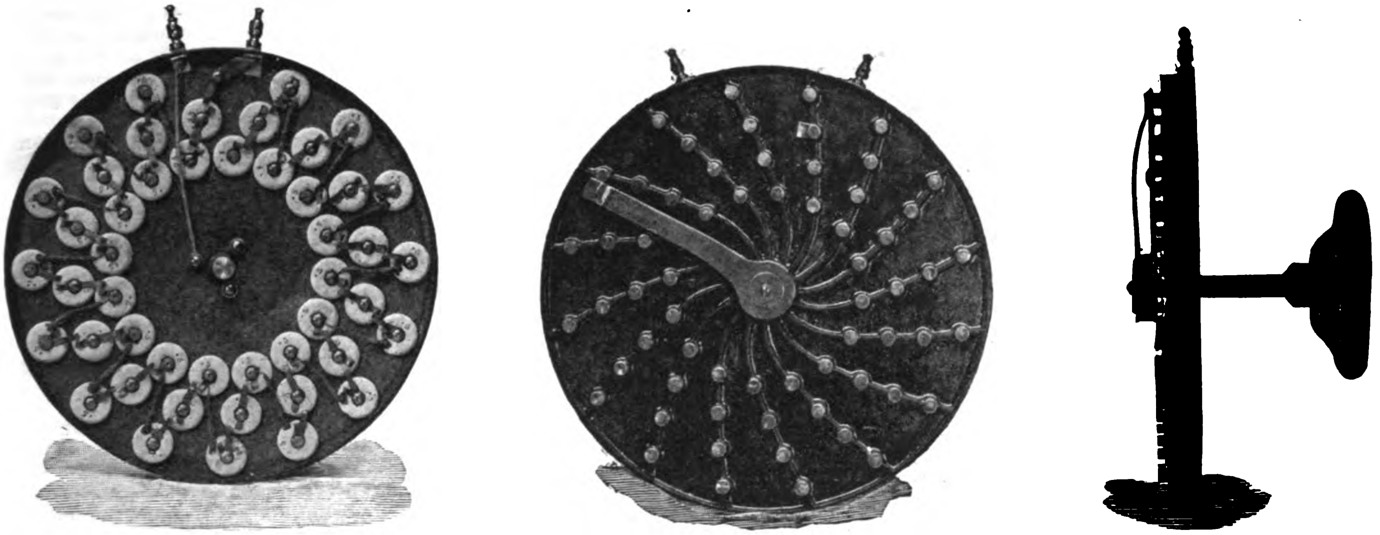
HON. J. SHANAHAN.—The death is announced of this gentleman at Tribes Hill, N. Y. He was well known as a canal official and a private contractor. At the time of his death he was president of the Cayadutta, N. Y., Electric Railroad and the Fonda, Johnstown and Gloversville Railroad.

COL. A. J. RUSSELL.—The death is announced of this gentleman, who was one of the pioneers in introducing the Edison system of electric lighting, and of late has been connected with the commercial use of the phonograph.

TRADE NOTES & NOVELTIES

THE "UNIVERSAL" FIELD RHEOSTAT.

It is well known that enamel rheostats are by far the most compact for a given capacity, are entirely fireproof (meeting all demands of the insurance requirements), have high insulation and are essential to the up-to-date switchboard. As heretofore constructed enamel rheostats have usually had all the resistance in one envelope of enamel attached to a cast iron plate, thereby making all the imbedded resistance a single unit which, if it failed in any part, destroyed the value of the entire plate, creating an expensive repair. Also because of this method of construction purchasers have been compelled to select for their needs from the standards established by manufacturers, or pay an extra price and be subject to considerable delay in getting supplied. As is well known, no two dynamo manufacturers make machines of similar capacity which have the same field resistance, and all manufacturers make changes continually in the windings and proportions of the dynamos they produce; therefore, without an infinite number of sizes, no manufacturer can carry in stock rheostats that supply just the external resistance required in each case.



Figs. 1, 2 and 3.—The "Universal" Field Rheostat.

In an endeavor to overcome these objections, and at the same time preserve all the advantages of the best that has been procured, the American Electric Heating Corporation have brought out a line of dynamo field rheostats, which, it is believed, will demonstrate that they have accomplished the desired results.

The rheostats consist of circular cast iron plates, in a number of divisions and resistance of the rheostats. These discs are of uniform size, but vary between wide limits in resistance and ampere capacity. The cast iron supporting plate is provided with suitable holes, which permit a single bolt to clamp the connections, discs and plate firmly together, and the bolt heads form the contact points over which the usual movable arm rotates. By this method of placing the resistances, one or more rows of contacts may be arranged, thereby distributing the resistance over a greater surface of a given size plate than has been the practice where all the resistance is located outside the circle of contact points. In the event of injury to any part of the circuit, it would require but a few moments' work of the dynamo tender to locate the fault, remove or cut out the defective part and continue the use of the rheostat.

The possibility of burn-outs is very slight and cost for repairs nominal. No disc can ever have more than its predetermined load, and the factor of safety allowed is large. Each customer can have exactly the rheostat required for his dynamo. Special rheostats within the limits of sizes made can be furnished at once. By reason of there being but a few sizes of plates required to meet all demands, but an infinite combination of resistances, no delay need occur in filling orders, for the average rheostat can be assembled in an hour, and it is a simple matter to keep an assortment of resistances complete.

All field rheostats for mounting on back of switchboard are made so that the holes drilled for one will answer for any size; so if it was desirable at any time to change from one size to another, it would involve no change in the supporting bolts or their location.

Quite an important feature is that if by carelessness an excessive overload is applied and allowed to remain to the point of causing a burn-out, no serious harm could be done; for at most but two or three of the discs could be injured. The connections are such that the field circuit cannot be opened if the arm fails to make contact.

STEEL POLES OF THE NATIONAL TUBE WORKS.

One of the largest iron and steel plants in the world, organized for the purpose of turning out a high grade special product, is that of the National Tube Works, at McKeesport, Pa. The company have been in business over 40 years, beginning originally in Boston and moving to the banks of the Monongahela about a quarter of a century ago. At the present day their plant extends along the river a full mile, and, in round numbers, some 10,000 men are employed in making up, from the raw material about 250,000 tons annually of pipe and tube, in iron and steel, particularly the latter. An idea of the scope of the company's vast operations may be formed from the fact that a mile of cars of coal invades its yards daily, and that the output ranges through 1,000 sizes of pipe and tube. The National Tube Works early recognized the coming importance and predominance of steel, and have a magnificent steel plant making a beautiful quality of high grade mild steel, all of which is practically used up by themselves. In other respects also the works are self-supplying, and thus the company enjoy great advantages when it comes to making prices in times of close competition. In the line of steel trolley poles the company have been very successful, having made sales to some of the largest railways in the field, and they have addressed their attention to meeting all the exceptional conditions involved in trolley line strains due to wind, weather and work. These poles, as well as those for lighting purposes, fully sustain the reputation of the time-honored "Diamond B," and "Boston Tubing" brands. The utmost care is taken in the preparation of the goods, and literally every ounce of material is under test, metallurgical, chemical and mechanical from the moment it enters the works till the hour it leaves for use. The different departments of the working features of the establishment are divided as follows: National Tube Works, Monongahela Furnaces, Monon-Forge and Iron Works, Republic Iron Works, Monongahela Steel Works and National Transportation Company. The company maintains sales offices at Boston, New York, Pittsburg, Chicago, St. Louis and is now establishing itself in like manner in London, England. The officers are: D. W. Hitchcock, president; A. F. Luke, secretary and treasurer; E. C. Converse, vice-president and general manager, Horace Crosby, assistant general manager, and F. R. Upton, sales manager. The National Tube Works Company is capitalized for $11,500,000, all paid in.

THE EMERSON 1897 MODEL INDUCTION CEILING FAN.

The Emerson Electric Manufacturing Company, of St. Louis, Mo., the pioneers in alternating fans, are this spring bringing out their 1897 model induction fans, both for ceiling and desk ventilation. These fans contain a number of improvements on the older models and make the fans thoroughly up to date. The accompanying engraving, Fig. 1, shows the ceiling fan complete, and Fig. 2 gives a detail view, showing its construction, the general appearance and design of the 1897 model being extremely graceful and artistic.

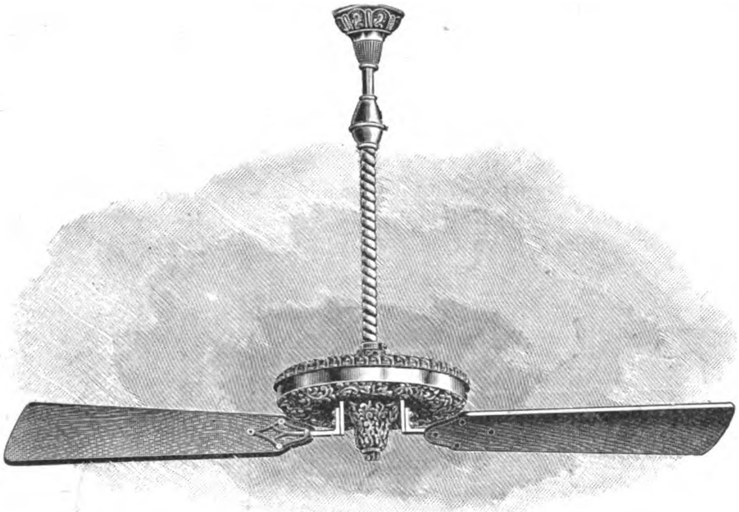


Fig. 1.—Emerson Alternating Induction Ceiling Fan, 1897 Model.

In general construction the motor is merely a "wheel within a wheel," the outside wheel (the field) being stationary, while the inside wheel (the armature) revolves on a large solid shaft on a ball bearing, immersed in a cup of oil. There is no moving wire, no commutator, no brushes, no reduction gear of any kind, no friction wheels and no wearing parts whatever, except one large solid bearing, and this revolves at only 150 to 210 revolutions per minute. It is claimed to be the ideal ceiling fan and to be far ahead in simplicity and construction even of the best direct current motors.

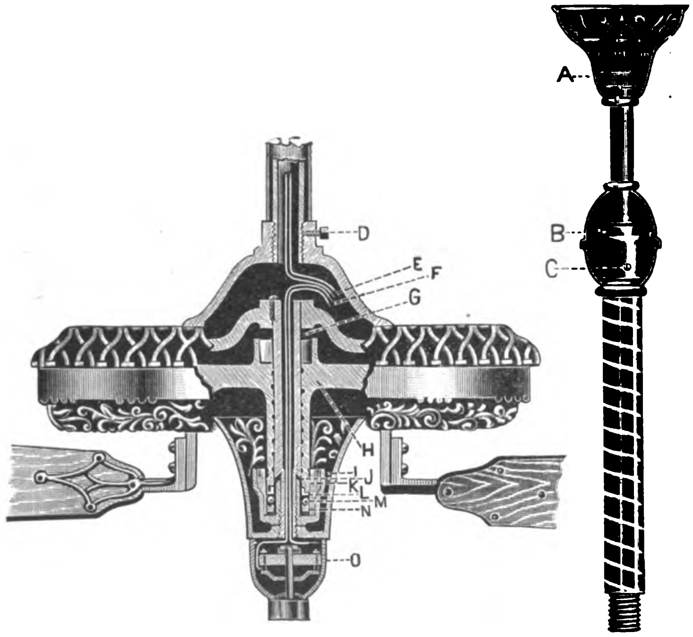

Fig. 2.—Emerson Alternating Induction Ceiling Fan, 1897 Model.

The standard finish is nickel plate but is furnished in brass plate, oxidized copper or any finish desired.

The bearing, as shown in Fig. 2, is merely a long upright shaft, with an oil cup screwed on the bottom; and on this shaft the armature revolves, resting on a ball bearing, M. The balls are standard hardened steel balls, which run on hardened steel ways, and are immersed in oil.

On this motor there is only one bearing to oil and only one place to oil it, and it is believed there will be only one time it will ever need oiling, and that is when it is started at the beginning of the season. The oil cup I is filled up to the point K, as shown. This should supply sufficient oil to last an entire season. By a unique device about one-half of the oil is carried up to the top of the shaft, thoroughly lubricating the same every time the motor is started, and runs down again when the motor is stopped, insuring perfect lubrication until the oil is actually used up.

The fan blades are large and have a wide sweep, and revolve at about 210 revolutions at full speed, but on account of its much greater speed, the angle is considerably less, to give the same results. The regulation in breeze is obtained by the switch, and the speed can be cut down to about 150 revolutions, by moving to a point one-half way between "on" and "off."

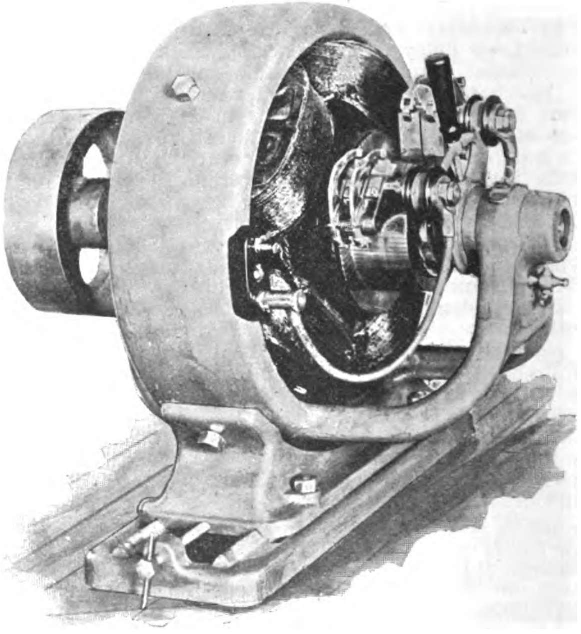
The switch O at the bottom of the motor performs two distinct purposes—to stop and start the motor, and also to regulate the speed. To start the motor, the switch is turned to the right till it touches the stop, and the motor will start itself promptly and run at about 210 revolutions per minute on 125 watts. To stop it, the switch is turned to the left as far as it goes, when the current is cut off. To run slow speed, the switch is moved half way between these two stops, after putting full on to start it and bring it up to speed, and the motor will run 150 revolutions per minute on 100 watts. By reason of the angle of the blades this makes a fine, gentle breeze.

The Emerson Company claim to have the only complete line of alternating current fan motors in the world, having eight distinct types, two each of 12-inch and 16-inch fans, for 16,000 alternations; one each of 12-inch and 16-inch fans for 7,200 alternations, and one each of ceiling fans for 16,000 and 7,200 alternations, and also claim that each of these types is the most efficient of its kind.

THE AHLM-EDWARDS ELECTRIC CO., MULTIPOLAR DYNAMOS AND MOTORS.

THE feasibility of electric power distributed to customers in small units has created a demand for motors especially adapted to such purposes.

Fully recognizing this fact, the Ahlm-Edwards Electric Co., of Medina, Ohio, have placed on the market a motor which in every respect meets the requirements for a machine of this class. By use of their patented adjustable base, whereby the motor may be fastened to the wall or ceiling, as well as to the floor, a large saving in floor space is attained. The motor is shown in the accompanying engraving.



The Ahlm-Edwards Dynamo and Motor.

For use in small isolated plants or private houses, the Ahlm-Edwards Electric Company manufacture a line of dynamos of moderate capacity which are designed with a special view of being driven from small steam, gas, or gasoline engines. Their plants of this kind have proved to be a commercial success wherever in operation, and the demand is rapidly increasing.

All dynamos and motors manufactured by the Ahlm-Edwards Electric Company are absolutely sparkless at all loads, as the greatest care has been taken in the relation between the speed, copper and iron, as well as their general mechanical design. The position of the brushes is the same for any load or overload that is ever met with in practice.

The shape and cross-section of the frame are carefully designed so as to avoid all stray or leakage magnetism, and a special grade of cast iron is used.

The magnet cores are made of cast steel, the pole faces of which are especially designed so as to evenly distribute the magnetic flux in the air-gap, and which serves to maintain a steady commutation field.

The bearings have bronze linings, and are provided with unusually large oil-wells and self-oiling arrangements.

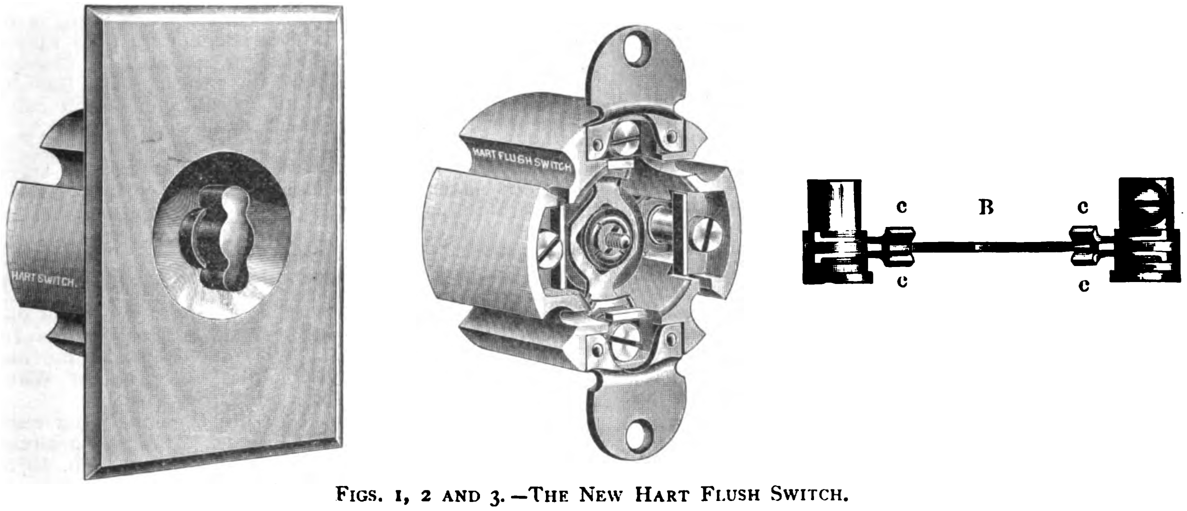
The armature core is built up of .016-inch-thick double-annealed sheet-iron discs which are well insulated by a coating of japan before being assembled. All the armature coils are interchangeable, and to insure safety against burn-outs, etc., they are wound, shaped, and insulated by hand before being placed upon the core. To prevent short circuiting or flashing over from brush to brush, an unusually large number of segments are employed, and sufficient brush surface to ensure cool running, even under considerable overload. Only drop-forged bars are used; and for insulating, the best India mica. All bars are interchangeable, and can easily be replaced.

The magnet coils are insulated and wound with the utmost care, and are all subjected to 6,000 volts alternating current before leaving the factory.

All the motors are provided with radial brush holders, which feed the carbon automatically, and when once set the brushes need no further attention.

SNAP SWITCHES—THE NEW HART TYPE.

WE have received the following interesting and timely article from the Hart & Hegeman Company, of Hartford, Conn.: The rapid increase in the number of incandescent lights during the past few years, has created a growing demand for appliances for controlling them and facilitating their use. One of the most used of these appliances is the snap switch, for placing the means of control of the lamps on an electrolier or elsewhere, within easy reach of the hand. Not many years ago, almost any sort of a thing that would, with more or less manipulation, light and extinguish the lamps, was considered good enough, regardless of its mechanical construction or its appearance upon the wall. Of late years, however, the demand has been for a more ornamental as well as a more durable and reliable article. Consequently snap switches have been greatly improved in their construction. This, however, does not apply to that class of switches whose only merit is their low price, and which are not in competition with the higher grade of switches.



Figs. 1, 2 and 3.—The New Hart Flush Switch.

The selection of a snap switch for use on a certain piece of work is frequently not given the importance that it deserves and it is regarded as one of the minor and unimportant details of construction, whereas it is one of those important details which should be settled by the selection of that switch which comes the nearest to fulfilling all the requirements of safety, durability, and convenience.

The chief requisites of a snap switch are quick and positive action when the actuating member has been turned or moved a predetermined distance, and, the locking of the automatically moving parts against accidental displacement, after such action has taken place. Equally important are the contacts, or that portion of the switch to which the terminals of the circuit are attached, and which serve to carry the current, by means of the switch plate, to corresponding contacts to which the terminals of the lamp circuit are attached. The contacts should have large contact area relatively to the amount of current to be carried, and should have a strong pressure upon the switch plate, or driven member of the switch. The large area is necessary to prevent "cutting" between the switch plate and contact surfaces, due to long use and neglect combined. The pressure is necessary in order to insure the permanency of the rated carrying capacity of the switch. If a light pressure is used, no cutting will probably occur; the switch will move freely, if the mechanism is reasonably good, and, for a time, it will carry its rated capacity of current without heating. In a comparatively short time, however, the surfaces depended upon to make contact, will tarnish and collect dust, and their conductivity will be impaired to such an extent that the switch will heat, and become worthless.

Aside from the fact, that the carrying capacity of a given area is regulated by the pressure, the pressure is also necessary in order that there may be sufficient friction to keep the contact surfaces in a proper condition to carry the current safely. Another cause of trouble is this, that if a switch plate, or its equivalent, "makes" contact by a movement the reverse of that by which it "breaks" contact, it is liable to carry back on the contact surfaces, the non-conducting metallic oxide formed by the repeated rupture of a circuit.

The form of contact which more nearly fulfills the above requirements, is that of the so-called "knife switch." This contact should be formed by two or more pieces of tough and elastic metal of good conductivity, held rigidly by one end, while the free ends press upon opposite sides of the switch plate, as in the usual type. These pieces should be of sufficient thickness to instantly carry off the heat produced by the rupture of the circuit, and prevent unnecessary burning at the point of rupture. While the contacts of the knife switch are desirable, its non-automatic action is objectionable, when used on comparatively small currents by the average user. Currents of large capacity are supposedly handled by persons of judgment, and with knife switches, in which a spring is used to assist the "throw." Under such conditions they answer the usual requirements.

From the foregoing facts it would seem that the switch best adapted for everyday use by everybody, on small currents, say, up to fifty amperes, is one in which the switch plate is carried automatically and surely into contacts which make contact at all times and under all conditions, and one which breaks the circuit rapidly and with equal certainty, simply by the turn of a handle, leaving nothing to the possible carelessness of the operator.

The manufacturers of the well-known Hart switch, recognizing the present requirements as to quality in all the details of construction, are bringing out a new line of switches which seem to embody all the essential features of a good switch. The flush switch illustrated in the accompanying engravings is a sample of the new line. This switch, in addition to heavy and durable mechanism and contacts calculated to stand severe service, is also "indicating." When the switch is "ON" the handle stands as shown in Fig. 1, and at right angles to that position when the switch is "OFF," the movement of the handle being continuously to the right by quarter-turns, with no possibility of its stopping in any intermediate position. The handles of all the switches of the same capacity are interchangeable without affecting the indicating feature. The same rule applies to switches in gangs. The handles are of the self-adjusting type heretofore used on Hart switches.

Fig. 2 shows the ten-ampere double-pole switch with finished face-plate removed, showing the mechanism and contacts enclosed by the base, which is one piece of porcelain. This base is provided with channels for the wire, the bared ends of which are clamped under binding screws, accessible from the face of the switch after it is put in position in the wall. This feature greatly facilitates the installation of the switch, and especially of switches in gangs. Any switch in a gang may be connected up or disconnected and removed without disturbing the others.

Fig. 3 shows the type of contact used. Each binding post is provided with a pair of spring bronze clips, c. Each end of the switch plate, B, is carried between a pair of these clips by the strong and instantaneous action of the switch mechanism. The connection thus made is practically perfect. The double-pole switches are double-pole, double-break and double-contact. Single switches and gangs of all sizes are carried in stock, with face-plates of any of the standard finishes. Any special finish can be furnished promptly.

A line of iron wall frames, and iron switch boxes for use with iron armored conduit, is also provided. No flush switch should be placed in a plastered wall without the use of such frame or box, or, its equivalent, to provide a secure attachment for the switch and to prevent the plaster from crumbling around the edges of the opening.

The Hart & Hegeman Manufacturing Co. feel that in producing this new line of flush switches they are taking one more step in the right direction, viz., the maintenance of and improvement in the former good construction of the "Hart Switch," and they are confident that the already large number of users of that switch will be increased.

"MASCOT" DRY BATTERIES.

THE first dry cell that attracted any attention in this country was the "Gassner" and a few thousand cells of that type were imported and sold at a very high price. The enterprising house of J. H. Bunnell & Co., with its usual foresight, believing that an efficient dry cell would find a ready sale, promptly put one on the market and they are, undoubtedly, the pioneers in bringing out the first practical, American made, dry battery.

The excellence of this battery, together with the able manner in which it was handled, soon made it an acknowledged commercial success. Notwithstanding the fact that it was handicapped with a heavy royalty, the Bunnell & Co.'s battery, on account of its acknowledged superiority, has continued in the lead and its sales are estimated to have reached about a million cells.

Messrs. Bunnell & Co. have recently extended and improved the facilities for making their "Mascot" dry cells, and the quality of these cells is guaranteed to be the best for strength, durability and recuperating powers; and the low price at which they are now being quoted would seem to justify the prediction that their Mascot Dry Cell will soon supersede wet cells for all open circuit work.

McEWEN ENGINES AND THOMPSON-RYAN DYNAMOS.

The McEwen Engine Company, of Ridgeway, Pa., have recently installed two 75-kilowatt Thompson-Ryan generators direct connected to two 14 x 15 center crank McEwen engines, in the Cambridge Springs Sanitarium, Cambridge, Crawford County, Pa. They have also furnished for the Hart Memorial Library, at Troy, N. Y., a 30-kilowatt direct connected plant.

Among the railway plants recently installed is one for the city power house of the Ithaca (N. Y.) Street Railway Company. The engine is a tandem compound condensing, 12½ x 25 x 20 inch stroke. The McEwen Works are busy on numerous orders.

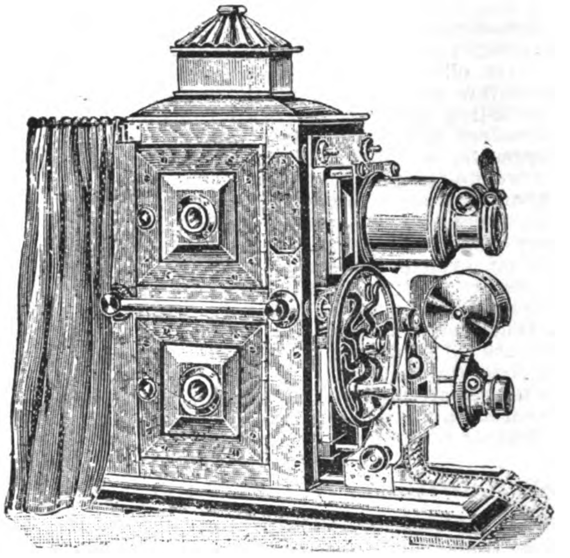
WHAT ELECTRIC ELEVATORS WILL CARRY.

It is recorded of the Sprague electric elevators in the Siegel-Cooper "Big Store," that the ten main passenger elevators averaged during the opening week 100,000 passengers, making 2,500 round trips, or a total of 94½ car miles per day. The plant was barely ready at the time, but there were no mishaps. The record is, it is said, without an equal.

THE MONARCH PROJECTING LANTERN AND KINEOPTOSCOPE.

Messrs. Riley Bros., 16 Beekman street, New York, are having a very satisfactory demand for their stereopticon magic lanterns, especially their Monarch double-projecting lanterns with kineoptoscope attachment, as shown in accompanying engraving. The kineoptoscope attachment is a most ingenious invention. In connection with the stereopticon animated photographs, living and moving pictures, in fact, every movement of actual life is depicted on the screens. The Edison standard films can be used in this apparatus, which is so well constructed as to allow the films to pass through freely without the least danger of injury.

The double apparatus here illustrated will take any ordinary lantern slide and is largely in use now for illustrating lectures, curtain effects, etc. The lower part of the stereopticon is used as the animated picture part and the top for throwing on the titles of films, etc. Experience has shown that Messrs. Riley Bros.' hand-feed electric lamp is the best and cheapest to operate in connection with their apparatus.



The Riley "Monarch" Projecting Lantern and Kineoptoscope.

It is light, portable and simple, taking, it is claimed, only one-tenth of the time required for getting ready lime light apparatus. By means of an adjustable rheostat it can be adjusted for from 500 to 2,000 candle power.

Messrs. Riley Bros. carry a large and full line of stereopticons, magic lanterns, lantern slides, films and all accessories. They have agencies established in many cities of the United States. Catalogues of their goods will be mailed to any address on application.

THE WATERBURY FINE-WIRE DRAWING MACHINE.

AMONG the many interesting exhibits shown in operation at the recent 25th anniversary of the Stevens Institute of Technology, was a fine wire drawing machine manufactured by the Waterbury Machine Company, of Waterbury, Conn.

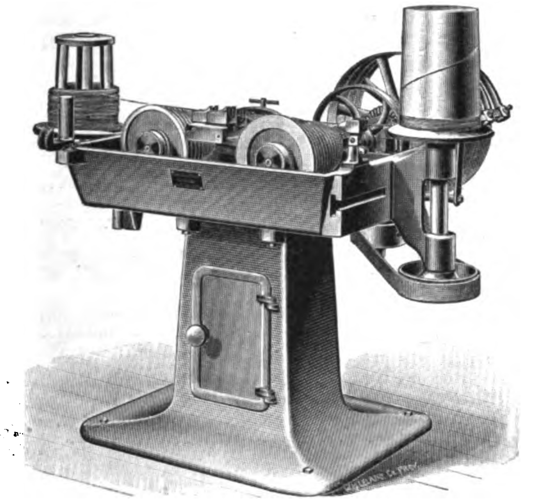
This machine, illustrated in the accompanying engraving, was designed by Mr. W. D. Pierson, a Stevens graduate, and is intended for drawing wire from No. 14 to No. 40 B. & S. gauge. Starting at No. 14 with copper or brass wire, the machine will draw continuously to No. 26, and from 26 to No. 40. With iron or steel wire the start is at No. 18 and the wire is drawn continuously to No. 30. The machine is also well adapted for drawing platinum, silver, solid and gold-plated wire. The machine will work ten dies or less, and both steel or diamond dies can be used, either separately or together, as preferred. The threading up is very simple, requiring but little time.

The wire being carried from the reel is passed through the first die, held in the die-holder between the drawing cones, and lapped once around the smallest step of the cone nearest the block, then carried back under the cones, then through the next die, and so on until the required number of dies are threaded.

The lubricating device is one of the principal features of the machine. The tank under the cones is filled with lubricant, and a centrifugal pump forces it through a hollow bracket and into the die-holders, which are provided with brass cocks to regulate the flow of liquid. In this way the dies are kept cool and clean, and the cones are also kept lubricated.

By means of adjusting screws in the several die boxes, the water is thrown against the inner surface of the die, keeping it clean and cool. The bracket which carries the block can be moved along so as to accommodate blocks of varying diameter, and also allowing the block to be driven in either direction.

The block is adjustable as to size and speed. Being driven by a belt from the underside, it can be run in either direction and at any speed. The drawing cone nearer the block is composed of sections securely keyed to the shaft, and each portion of these sections which is subject to wear and on which the wire runs, is covered with a hardened steel ring. This desirable feature is a recent improvement. The other cone is composed of sheaves revolving loosely on the shaft, the speed being governed by the travel of the wire.



THE WATERBURY FINE-WIRE DRAWING MACHINE.

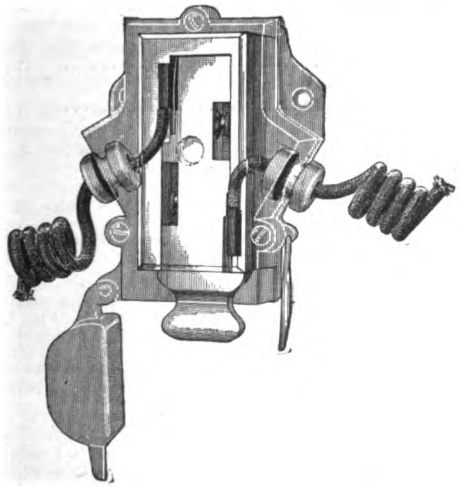
As a matter of convenience for the operator, the machine is geared so that for whatever size block is used, by putting that same diameter pulley on the vertical block shaft, the speed of the block will always be correct.

In the construction of this machine special attention was devoted to making it strong and rigid, as well as convenient to handle, and a workman can operate a number of these machines at the same time. The gears are all cut and the bearings babbitted, the best metal being used. The machine is provided with tight and loose pulleys 18 inches diameter and 4 inches face.

The Waterbury Machine Co., also manufacture a variety of other continuous wire drawing machinery both for large and small sizes.

FRANCE & JONES FUSE BOX.

MANY engineers and central station managers, and especially those who have had experience with high potentials, condemn the use of double-pole fuse boxes, on account of the possibility of short circuits; also the use of fuse boxes attached to transformers on account of the possibility of short circuits across the frame of the transformer, thereby throwing a whole section out of service until trouble is located, but are now recommending the use of dummy transformers protected by single-pole fuse boxes, separate from the transformer, and also the protection of each main by single-pole boxes.



FRANCE AND JONES FUSE BOX.

As in this case, trouble will locate itself, and to meet the above requirements Messrs. France & Jones, of Tacony, Pa., have placed upon the market a new fuse box, which has many advantages. All terminals are encased and held in position by grooves in the porcelain, thereby doing away with the screws, which often become loose and give trouble, such as short circuits, loose terminals, etc. This way of holding the terminals also avoids the necessity of having holes through the porcelain for the screws to pass through, which, in many cases, are the cause of short circuits and leaks through the frame of the box.

As shown in the accompanying illustrations, the leading-in wires pass in through porcelain bushings and are soldered to the terminals, avoiding all trouble from loose connections. The construction of the plug is such that it is impossible to arc from terminal to terminal through the blowing of a fuse. To replace a fuse it is not necessary to handle the box. As the small wire or catch on the right is pushed to one side, the lid drops, and the handle of the plug is exposed and can be pulled, the fuse renewed and plug returned to the box.

ADVERTISERS' HINTS

THE CONOVER MANUFACTURING COMPANY, 26 Cortlandt street, New York, have recently installed their apparatus in the Dorchester station of the West End Street Railway Company, Boston. They state their condenser is the only one sold under a duty guarantee.

F. N. ROEHRICH & CO., 108 Fulton street, New York, make a specialty of designing manufacturing plants and special machinery and are at all times pleased to enter into correspondence with interested parties.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., recommend Dixon's traction belt dressing as the best thing for slipping belts and preserving the life of the leather.

THE LINK BELT ENGINEERING COMPANY, Nicetown, Philadelphia, supply all classes of link-belt machinery, including coal and ashes handling plants, elevators and conveyors.

DIEHL MANUFACTURING COMPANY have opened an office at 192-194 Van Buren street, Chicago.

THE CONNECTICUT PIPE MANUFACTURING COMPANY, West Haven, Conn., state they are the original patentees and manufacturers of cement-lined ducts. They contract for the complete engineering and laying of subways.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., are advertising their well-known alternating current ceiling fans and fan motors made in a variety of styles and to suit all voltages.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, are just now directing attention to their stock of railway supplies and specialties.

THE COX THERMO-ELECTRIC COMPANY, LTD., St. Albans, England, whose laboratory was recently destroyed by fire, have already secured temporary quarters and will receive orders for their generators, subject to delay.

HARVEY HUBBELL, 33 Organ street, Bridgeport, Conn., is manufacturing improved tapping machines, screws and machine screws for electrical purposes.

THE EDISON MANUFACTURING COMPANY, 110 East Twenty-third street, New York, furnish special X-ray plates for radiographs.

M. T. HORN, 42 Dey street, New York, furnishes metal tubing seamless or brazed for electrical and scientific purposes. Any size to order.

J. H. BUNNELL & CO., 76 Cortlandt street, New York, are furnishing the "Mascot" dry battery at 50 cents per cell.

A. W. FRANCE, Tacony, Pa., is selling a fuse box which, he says, cannot arc from terminal to terminal or from porcelain to case.

J. G. BIDDLE, 906 Drexel Building, Philadelphia, Pa., is introducing the "W-S" X-ray machine.

THE HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., have brought out another line of flush switches. They are "indicating," wired from the front, are encased in porcelain and have self-adjusting handle.

THE BELKNAP MOTOR CO., Portland, Me., are advertising the Chapman voltage regulator for controlling the voltage of varying speed dynamos. It is an automatic device, magnetically controlled, by which a variation of 25 to 50 per cent.

in speed of water wheel or engine is brought within 2 per cent. of the normal.

NEW YORK NOTES.

THE STANDARD AIR-BRAKE COMPANY, New York, reports good business for March, and in addition to deliveries at home, secured several good orders from abroad, including one by cable for air brakes for the British Colonies.

E. J. WARING, 136 Liberty street, reports doing a good trade. His "Daylight" electric desk lamps are giving satisfaction wherever placed, resulting in many duplicate orders. Mr. Waring will be pleased to mail price list, etc., to any address on application.

EDWARDS & CO., 144th street and Fourth avenue, New York, have recently installed a 24-inch motor gong of their make on the end of the pier, foot of East Twenty-third street, New York, for the Greenpoint Ferry Company. It is to be used as a fog bell. It is giving first-class satisfaction. Messrs. Edwards & Co., report orders for their bells from several other companies.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has declared a regular quarterly dividend of 1¾ per cent. upon its preferred stock.

PETERKIN & PETERSEN, electricians, Niagara Falls, N. Y., are bringing out a new cell which they call the Electric City battery. They are exhibiting in their show window the Brunell third-rail street car system.

THE GOODYEAR VULCANITE CO., 353 Broadway, New York, manufacture and carry a full line of hard rubber goods of almost every description suitable for electrical purposes. Their immense factory in New Jersey is kept busy full time and is equipped to fill any special order at shortest notice. The Goodyear Vulcanite Company solicit correspondence regarding their lines.

WESTERN NOTES

THE ELECTRIC APPLIANCE COMPANY advise their customers, and the electric railway trade generally, that they have made arrangements with the Ohio Brass Company to carry a complete line of their railway specialties in Chicago stock. The electric railway trade will undoubtedly appreciate the advantage of being able to send large or small orders for the celebrated Ohio Brass Company's specialties, and have the goods shipped from Chicago on the day the order is received. Both the Ohio Brass Company and the Electric Appliance Company hope this arrangement will be appreciated by the users of electric railway material.

MR. J. N. BROWNLEE, of Brownlee & Co., the large producers of poles for electrical purposes, has been in New York on an Eastern business trip. He reports business as good not only in poles but in cross arms, for which there has been a very large demand.

MR. S. C. Dyke, of the Brunt and Thompson Manufacturing Company, of East Liverpool, O., was in the city last week, and stated he was making a little trip among the chief Eastern cities. Mr. Dyke reports that there has been an unprecedented demand for their new regulating socket, and that they have hard work to keep up with their orders.

THE FOREST CITY ELECTRIC COMPANY, Cleveland, O., have issued a very pretty circular, with cover, relative to their roll drop and drop forged commutator bars. It mentions nearly 50 concerns whose style of bars it makes and quotes warm testimonials from a great many others, such as operating street railway and lighting companies and repair concerns. The indorsements could not well be stronger in regard to this very useful specialty.

CONOVER-GOE COMPANY, Monadnock Building, Chicago, have issued a pocket kinetoscopic reproduction of the great prize fight. It is full of go, and one can con over the whole affair quietly and at leisure by running his eye across its nimble pages. The number of copies given out is necessarily limited.

THE ROYAL ELECTRIC COMPANY, of Peoria, have just issued another edition of their pamphlet entitled "Facts Worth Considering." This pamphlet contains useful information for central station owners, and will be mailed to all who desire a copy.

THE NOWOTNY ELECTRIC COMPANY, of Cincinnati, have on exhibition at 36 Dey street, New York, some of their new long-burning improved arc lamps, which can be used on either constant current or constant potential circuits. Mr. L. R. Keck, president of the company, was in New York for a few days last week introducing these lamps to the trade.

NEW ENGLAND NOTES

THE AMERICAN CIRCULAR LOOM COMPANY, of Boston, have opened a branch office for the sale of their well-known flexible conduit at 27 Thames street, New York, and have installed Mr. H. B. Kirkland as manager. Mr. Kirkland has been for years associated with Mr. C. D. Doubleday, is thoroughly familiar with the conduit business, and is so well and favorably known to the trade that he requires no introduction here.

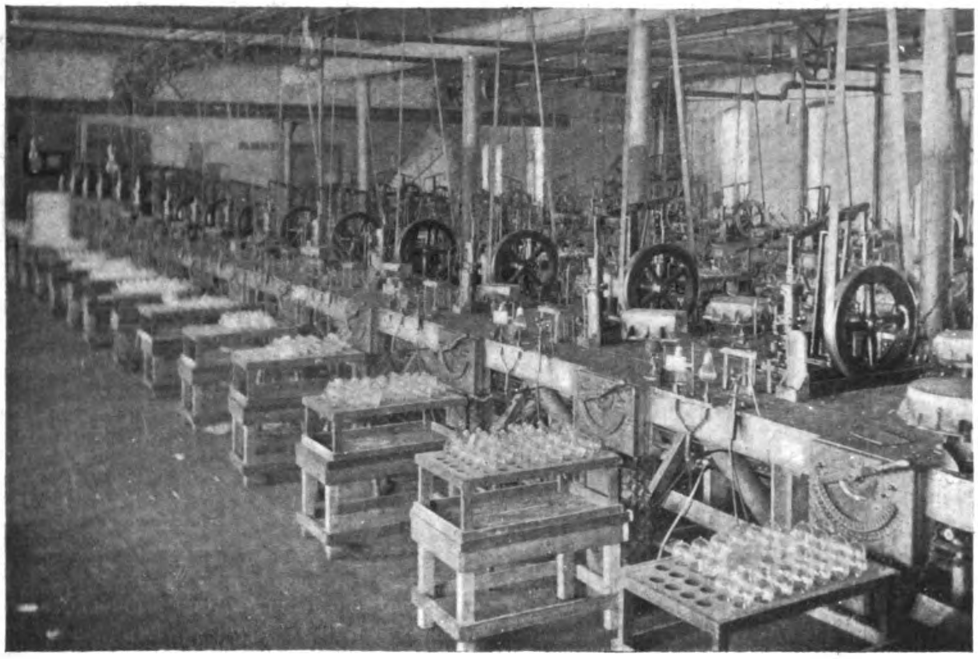
ELECTRIC LIGHTING

EXHAUSTING LAMPS BY THE "CHEMICAL" METHOD AT THE EDISON LAMP WORKS.

THE exhaustion of incandescent electric lamps has up to the present been almost universally done upon mercury pumps. Two classes of pumps have been generally used, the Geissler, and the Sprengel pump. The Geissler pumps have always been made of quite large capacity, and the lamps have been placed upon the pumps in groups, usually of about a dozen, all of which were exhausted together, and to all of which a current was applied at the same time, and under the same conditions.

The engineers of the General Electric Company's Edison lamp works have always advocated the use of the Sprengel pumps, rather than the Geissler pumps, because they can be made of such small size, that each lamp can be advantageously placed upon a separate pump and exhausted independently of any other. The advantages of this system are, that a leak in any lamp affects no other lamp and is readily detected by the failure of one pump to get a high vacuum, and the breakage of any lamp, in any way, during the process of exhaustion, does not interfere with any other lamp.



New Chemical Process of Exhausting Incandescent Lamps. View in Exhausting Department, Edison Lamp Works, Harrison, N. J.

From time to time during recent years, mechanical vacuum pumps operated without mercury, have been brought before the public, and while the engineers of the General Electric Company have fully appreciated the advantages of such pumps, they have been prevented from adopting any of them, owing to the large size in which these pumps have invariably been made, the object of their inventors being to exhaust a very large number of lamps at the same time, which the General Electric Company's engineers have always considered bad practice.

Recently this company succeeded in obtaining a small mechanical vacuum pump, whose rate of exhaustion is such that it can practically be employed to exhaust only one lamp at a time. Experiments were begun with these pumps about a year and a half ago. These early experiments showed that lamps could be exhausted to a degree much nearer perfection than by any previous method employed, as the various phenomena of exhaustion are clearly marked so as to enable a very definite rule of operation to be worked out. Lamps exhausted by the new process when compared with those exhausted on mercury pumps, have proved to be superior to them in every respect, including length of life and ability to maintain their initial candle power during their life.

The success of these early experiments led to the rapid introduction of these small pumps, so that now nearly the entire product of the Edison Lamp Works is exhausted by them. A large number of these pumps have been in operation several months and are very satisfactory. One aisle of the new pump room of the lamp works is shown in the accompanying illustration. The pumps are arranged in rows, as shown. Each pump has two cylinders, each employé using one cylinder only.

The final perfection of the vacuum, however, is not obtained by the pump unaided. The natural residual gases in an incandescent lamp may be called conducting gases, as they allow currents to pass through them from one leg of the filament to the other.[1] By any other method than the one we are now describing, the last traces of these gases are very hard to remove from the lamp, and are very injurious if not entirely removed. Their removal requires a long time on the mercury pumps generally used. By the new method, usually called the chemical exhaustion, when a pump has taken out all but the residual gases, a gas capable of combining with these residual gases, is introduced into the bulb. Previous to this introduction, the bulb, while the carbon is at a high degree of incandescence, is filled with a sort of blue glow; shortly after the introduction of the gases, and while the carbon is still at a high degree of incandescence, the blue glow suddenly disappears, indicating that a combination has taken place between the natural residual gases, and the introduced gas. When this combination takes place the lamp is ready to be sealed off, and the vacuous space is found to be in a thoroughly insulating condition. The advantages of this method of exhaustion are:

First: The phenomenon of the introduced gas combining with the residual gases, and thus perfecting the exhaustion, is so marked as to make the perfection in each lamp more certain than by the old method.

Second: Lamps are exhausted one at a time, and the whole attention of the operator is given to each lamp, insuring the proper manipulation and application of the electric current, and the final perfection of the vacuum in each lamp, which is so difficult to get in lamps which are exhausted in groups.

---

[1] See the paper read by Mr. John W. Howell before the A. I. E. E., Elec. Engr., March 17 and 24.

Third: The operator does the work sitting in a comfortable position, does not get tired, and can do as careful and accurate work late in the afternoon as early in the day, which is not the case in systems in which the operators are obliged to stand while doing their work.

Fourth: The lamps are conveniently arranged by the side of the operator, and get the least possible amount of handling. This fact alone saves considerable breakage.

Fifth: The injurious effects of mercury upon the health of the operators are entirely avoided.

It is gratifying to find that a new method has been discovered which results in a much greater degree of certainty of duplicating results in the pump room, thus removing one of the most serious obstacles in the past to greatly advancing the average quality of lamps and the consequent general improvement in incandescent lighting.

THE ISOLATED PLANT AT THE HILLSIDE HOME, SCRANTON, PA.

BY H. B. COHO.

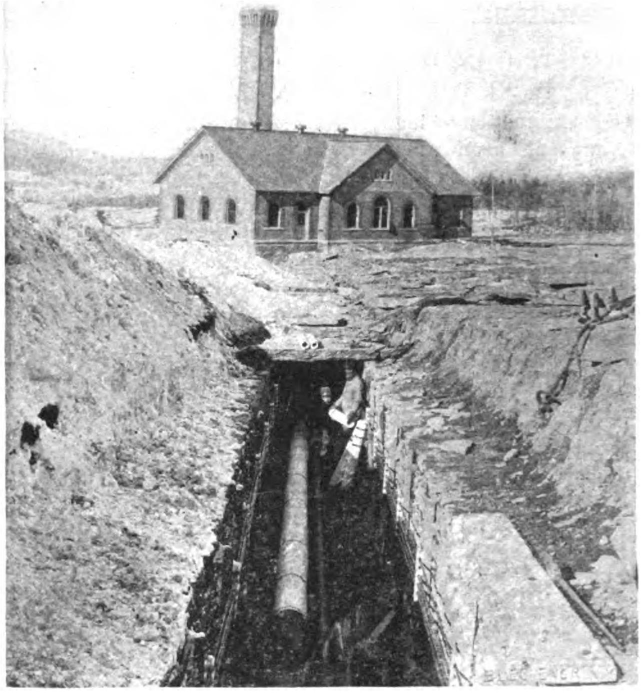
Mrs. Frances B. Swan.

In view of the deep interest of The Electrical Engineer in the success of isolated electric lighting plants, and of the fact that a plant which my firm has recently had the honor of installing embodies many noteworthy features, I venture to give a few details, such as the readers of an electrical journal would like to know. The success of such a plant as the one I propose to describe briefly, is, of course, an argument for the installation of other like plants; and when one sees the direct good and benefit resulting to those who are subjected to the new conditions thus introduced by electricity, one learns the importance of many features quite outside of commercial considerations. It has been said that a new thing to be successful must be a luxury and be taken up by the rich. My own observation goes to show that the rapid introduction and success of the electric light is largely due to its merits being proved in the numerous isolated plants installed in asylums and public institutions of all kinds, where intelligent charity has gathered together the old, the poor, the insane, and the generally lower elements of society. In such places, electricity has shown itself to be a boon of the first magnitude.

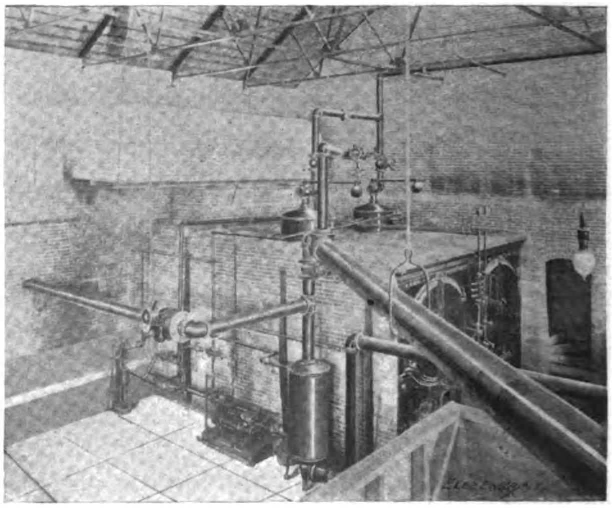
When the question of equipping the Hillside Home at Scranton, Pa., with electric light first came up, the board of directors, consisting of Mrs. Frances B. Swan, Messrs. Fuller, Dr. Payne, Murphy, Langstaff, Shotten and Terpie, discussed the question from a permanent investment standpoint, and appointed Messrs. Fuller, Payne, Langstaff and Mrs. Swan, a committee to investigate the various forms of electrical equipment and to purchase that which in their judgment proved the most desirable. Mrs. Swan, whose picture is here shown, was chosen chairman of the committee, and, although it is not a part of our report, it may be of interest to Engineer readers to know that at this time Mrs. Swan was the only lady Poor Director in the State of Pennsylvania and had served five years. Hence her selection as chairman was not made in polite deference to her as a woman, but because she was a director of long experience and exceptional judgment. Mrs. Swan, with Messrs. Payne and Langstaff, visited New York on one of our hottest days last summer, and she was the most energetic of the party in going from one torrid engine room to another. The contract was finally awarded to Messrs. H. B. Coho & Co., who designed and laid out the electric plant, as described further on.

THE INSTITUTION.

Before going into the details of the electric plant proper, it may be well to describe the situation of the institution and give a short history of its existence. Hillside Home of the Scranton Poor District is situated two miles from Clark's Summit, Pa., and was established by legislation April 9, 1862. At that time the town of Scranton was a mere village compared to its generous extent and growth to-day. On July 23, 1862, the first pauper was received, and on Jan. 19, 1863, the first insane patient. The first building was a small two-story frame building still extant. From this modest beginning the present magnificent structure has grown, and the superintendent, Mr. George W. Beemer, is responsible to-day for the welfare of five hundred people, while the property is valued at $500,000. This increase in the number of paupers and insane is in proportion to the population, but to my mind it would seem to indicate that in these advanced days our less fortunate fellows are cared for with so much greater care, that the skeletons of many families are no longer concealed in closets, but in our well-run and humane institutions. I desire to say here that although I spent many days on the premises while supervising all parts of the installation, I never saw a patient treated with anything but the utmost consideration, that being the main principle of Mr. Beemer's method, and one in which he is ably assisted by Mrs. Beemer, the matron, and Dr. Strang, the resident physician.

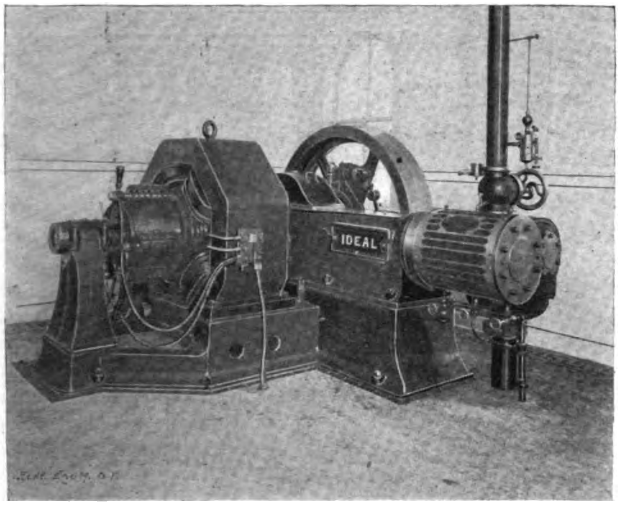


Electric Light and Power Station, with Subway, Hillside Home, Scranton, Pa.



Boiler Room, Hillside Home, Scranton.

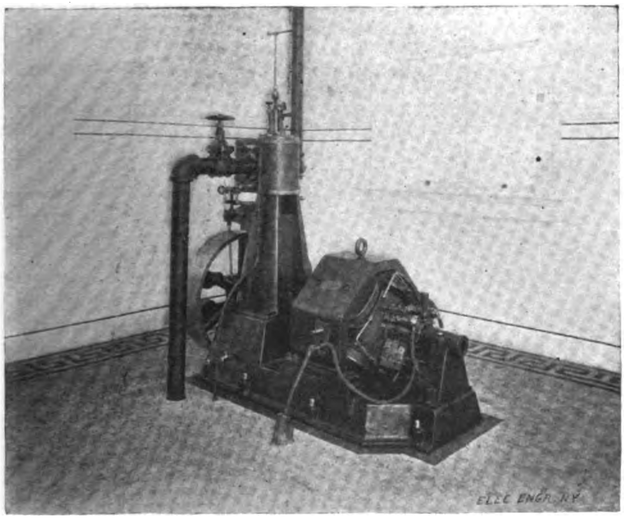
The benefit of the electric light to the patients is well stated in Dr. Strang's report to the directors, and from which I quote as follows: "The effect on the patients, when the change from oil lamps and gasoline was affected, was magical, and now in the evenings these poor unfortunates resort to games and music instead of sitting around moodily until ordered to bed. The improved ventilation, by means of electric fans, is also of tremendous advantage, and I venture to say that not only has your board of directors made a wise investment in your electric plant, but you have also improved the condition of the patients a hundred per cent." As will be seen from the above, the doctor believes in electricity; and I now go on to give a detailed description of the plant.



Large Lighting Unit, Hillside Home.

STEAM AND ELECTRICAL EQUIPMENT.

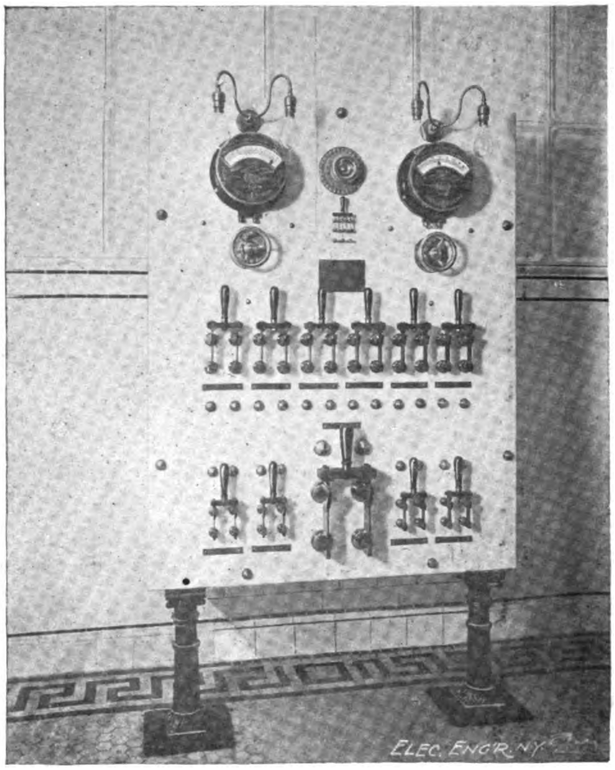
In describing the electrical equipment of the Hillside Home, I will first take up the generating plant. It consists of two Oswego boilers of 100 horse power each, one 14 x 14 Ideal engine, and 75-kilowatt Eddy dynamo directly connected, and one 6 x 8 Shepherd engine and 15-kilowatt Eddy dynamo directly connected. The large unit is used from the time the light is required in the evening until the heavy load is over for the night, when the little machine is started and run for the balance of the night, and during the day. The method of wiring will be described later. A special word may be given to the flue of the boilers, as is shown in the engraving. The flue is made entirely of brick, supported by iron girders, and so constructed that a return draft is effected, and this in connection with the fine stack, makes the finest natural draft I have ever seen. The damper is of the ordinary butterfly type controlled by a damper regulator and so perfect is the regulation that all the operator has to do is to keep his fire going and see that the pump keeps the proper amount of water in the boilers. Another fine feature of the boiler plant consists of its McClave grate bars. These grates enable the fireman to clean one-quarter of his fire at a time and an ordinary fireman can clean his fires without losing a pound of steam.



Small Lighting Unit, Hillside Home.

Besides the damper regulator, the plant is supplied with a Snow steam pump, a Metropolitan injector and a National feed water heater. The boilers are supplied with water from a cistern placed under the machine shop floor. This cistern is supplied from a spring, which the foresight of Mr. Beemer, the superintendent, led him to buy some years before. By this act of foresight, Mr. Beemer is independent of his driven well, and has a double supply of water always on hand.

The finish of the engine and boiler rooms is of the best, the engine room being tiled with white tiles. The mains from dynamo to switchboard are laid under the floor and the main steam pipe is the only overhead work in the engine room. The switchboard shown in the picture is of white marble and is extremely complete. Each switch controls a building, and in addition, there is an independent night circuit, which by the means of two switches is thrown on or off either machine. This arrangement gives the engineer control at all times, and at a certain hour of the night enables him to turn out all but those lights which it is necessary should burn all night. While on the subject of night lights, let me point out what an advantage this is in itself. Under the old methods the attendants were obliged to use lanterns and were constantly at the mercy of some unbalanced patient, with consequent risk of fire.



Switchboard, Hillside Home Electric Light Plant.

ELECTRICAL WIRING.

The object in view in designing all the wiring has been to conceal everything, and in so far as possible, keep all the lights out of the reach of patients. To accomplish this, a form of picture molding was used in the wards. The molding resembles an ordinary picture mold, and at the same time is used as such. The effect of this is shown in the cut and is decidedly pleasing. Where it was not practical to run molding, the walls were chiselled and the wires placed in iron conduit and run to the middle of the rooms, the rooms being lighted by clusters placed close to the ceilings and protected by heavy opaque glass globes.

The wires are all run to junction boxes, and each circuit is fused and controlled by a baby knife switch. Two sets of risers are run on each side of the building, one for main load and one for night circuits.

The increased protection against fire in this installation is very marked, each branch circuit being fused, each ward being fused, and each riser, besides the main switchboard fuse, thus making four sets of fuses from lamps to dynamos.

MAINS.

The mains from the power house to the various buildings are run in a trench, as shown in the picture. The tunnel is 800 feet long, 5 feet wide and 6 feet deep. It was dug and walled in by the inmates, under the directions of the superintendent. The mains are run with positive wires on one side and negative on the other. The wires were placed on insulating knobs and are readily accessible at any time.

STEAM HEATING.

The old steam plant has been done away with and a 10-inch main run up the tunnel intd which all the exhausts are run. By this method, in all except extreme cold weather, they are enabled to heat the buildings with only the exhaust. All the returns are run into a tank and are pumped back into the boiler.

MOTORS.

Motors are used to run the laundry and the pumps and have also been used for threshing. They are also used for ventilating purposes. The idea in mind all the time, has been to make one central power house, and the result of this is shown by the fact that the coal saving alone is at the rate of over $3,000 per year.

CORRIDOR IN HOME, WITH LIGHTS FROM MOULDING, OUT OF REACH.

From the above facts, the electrical installation at Hillside Home will be seen to do two things. It saves the county 10 per cent. on the old style of lighting and at the same time they are getting 200 per cent. more light. In addition, the comfort, health and security of the unfortunate charges has been increased beyond all measure, so that I may claim that in this case electricity has proved both a financial success and a physical and mental healer.

HARVESTING ICE UNDER THE ELECTRIC LIGHT.

KINGAN & CO., Ltd., the pork and beef packers of Indianapolis Ind., write us: "As you well know, the harvesting of ice is something that must be done in a very limited space of time, and it becomes necessary for us to work night and day. For this reason, we have resorted during the past winter to the use of electric lights. We had intended sending out a dynamo from our packing house and running it directly from our power engines operating our elevator. But, finding that the neighboring park at Broad Ripple had a plant which was not in use at this time of year, we started it up for them. We ran wires to the ice houses along our runs and elevators and also out on to the ice, using arc lights. This has been done by so many people that we cannot claim any novelty for it, but we can cordially recommend the use of electricity for this work, as it enabled us to cut and store ice almost as well by night as we did during the day. The lights or wires in the ice houses are permanent; we simply disconnect the lamps and carry them from one house to another as each fills up. With regard to work out on the ice fields, we string our wires on a movable frame, which is pushed around as our cutting advances from point to point."

ROENTGEN RAYS

AN APPLIANCE FOR SECURING PROPER RADIOGRAPHS OF FRACTURES ABOUT THE ELBOW JOINT.

BY FRANCIS S. KOLLE, M. D.

TO secure perfect and satisfactory radiograms of the elbow joint is a difficult task, especially when the joint is swollen and painful and the patient unable to extend the forearm. In children especially have I found it difficult to obtain a good negative, where the mere suggestion of straightening the arm caused so much fear of pain, that the attempt to optain any picture had to be abandoned. Not until lately have I secured the desired results.

My work in this direction has been stimulated by the failures of other radiographers, to produce the necessary and important results, confirming either dislocation or fracture about the joint in reference. The usual radiograms are made in the semi-extended or practically the lateral angular splint position, where the palm of the hand faces the film of the dry plate.

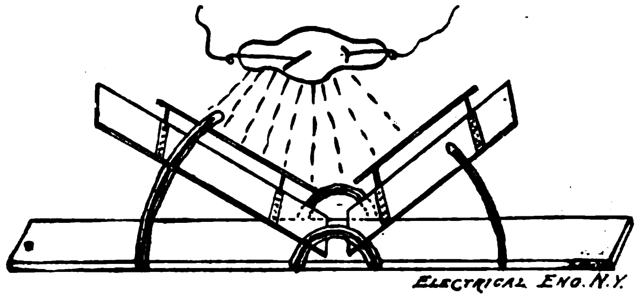


FIG. 1.—KOLLE'S FRAME FOR TAKING RADIOGRAPHS OF JOINTS.

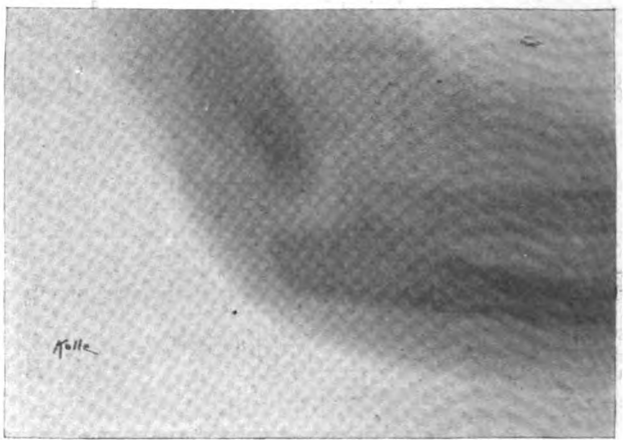

FIG. 2.—RADIOGRAPH TAKEN FROM THE SIDE, SHOWING NO FRACTURE.

That a picture taken in such a way will not show the proper relation of the articulation of the bones with each other is self-evident, and a fracture of either condyles is only brought out by an over-exposure, wherein the larger bones have been rendered transparent or penetrated sufficiently to leave shadows corresponding to the piece of displaced bone or fragment. That this is not only true of the elbow joint can be readily imagined, as fractures about the ankle and wrist joints would give the same results. No one would think of taking a radiogram of the wrist joint from a lateral point of view, if a fracture of one of the bones making up that joint was presented, and yet a number of failures to locate fractures or to diagnose dislocations have been recorded, only because the operator failed to consider the anatomy of the subject in hand. What is necessary is to make a picture of the joint in such a way that the entire joint is exposed, and that is in the antero-posterior position. Not only is the relation of the bones making up the joint shown, but a fracture or displacement of the fragments in such is readily demonstrated.

That there are certain conditions in which a lateral view is necessary, I do not dispute—a knowledge of the anatomy, making up the bony skeleton of such parts will, of course, assist the radiographer in these cases.

Now, it will be asked, How can one secure an antero-posterior view of an angulated or fixed joint, assuming that the patient cannot extend the arm? The answer is this: "Use two plates, bandaged to the posterior surface of the arm in such a way that they will form an angle, corresponding to the angle of the semi-extended arm and overlapping one another."

To accomplish this and partially to avoid movement, I have devised the cradle illustrated in Fig. 1. It is composed of a base, containing two movable shelves of wood, moved in an upward direction, and so forming an angle with one another, and retained in position by the aid of thumb-screws. A sliding device is added to allow of the use of wider plates than the actual width of the shelves; these are also fixed like the former. The arm is laid within the cradle, the two movable pieces of wood are approximated and fixed into position, allowing the arm to rest easily within the angle so formed, and, if need be, the arm may be bandaged to the shelves, which is particularly advantageous with children. The plates are laid between the posterior surface of the arm and upon the shelves, overlapping one another slightly. The tube is placed as shown in the illustration. An exposure of 30 seconds in children is sufficient and one to two minutes in adults will give a good negative, using a 6 to 10-inch spark coil.

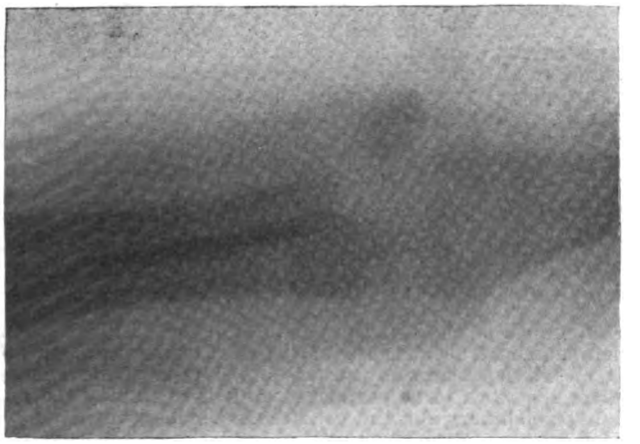

FIG. 3.—RADIOGRAPH TAKEN FROM FRONT, SHOWING DISTINCT FRACTURE.

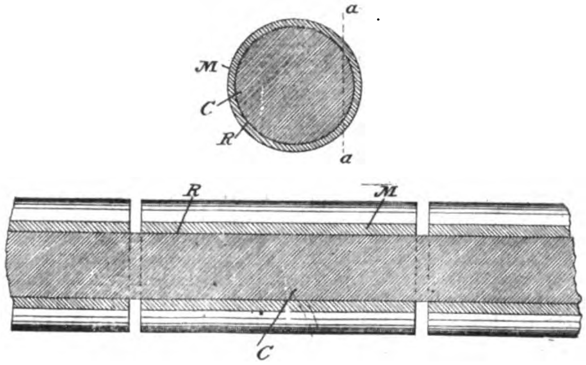
The prints made from the plates so obtained, are cut where the plates overlapped and are mounted upon the usual mount as one print. If the latter is neatly done, the finished picture will be both exact and reliable. The accompanying illustration, Fig. 3, is a radiograph made in the manner described, with a half-minute exposure and where previous pictures failed to show the fracture so plainly shown in this picture.

"THE TELEPHONE" is the name of a new electrical monthly, which is frankly anti-Bell and "independent" in its leanings. It is a clean, bright, well-printed paper, with Mr. W. R. Mackrille as editor. We confess we do not see any need for any more electrical papers, but each, whether old or new, must stand on its merits, and this the latest comer makes an excellent bid for patronage in a special department, being done in a thoroughly journalistic way. One of its items of news is that there is new material available for defeating the Berliner patent should it live after the Supreme Court gets through with it. The publication office is in Chicago.

TELEPHONY AND TELEGRAPHY

STONE'S COMPOUND TELEPHONE CONDUCTOR.

IT has long been observed in telegraphy that in many instances, owing to the relatively great electrostatic capacity and resistance of the conductors along which the variable telegraphic currents are transmitted, but a small portion of the current developed at the sending end of the line proceeds all the way to the distant or receiving station, and that, moreover, in such cases the current-waves which do reach the distant station are not of the same form as that in which they were when they set out on their journey from the transmitting end of the line. The first of these effects is termed "attenuation" and the second is termed "distortion." Attenuation and distortion, as might be expected, were found to be more pronounced in the case of submarine cables, and especially in the case of Atlantic cables, on account of their great length and relatively great electrostatic capacity. At a later date, when it was attempted to transmit telephonic currents over circuits of relatively great electrostatic capacity and resistance, attenuation and distortion were again observed and were found to be even more pronounced in the case of the rapidly varying telephonic currents than in the case of the more slowly variable telegraphic currents.



FIGS. 1 AND 2.—STONE'S COMPOUND TELEPHONE CONDUCTOR.

It has been determined, mathematically, that the evil effects of excessive distributed electrostatic capacity along circuits can be greatly reduced by the addition to the circuit of suitable distributed inductance or self-induction, and in order to apply this method Mr. John S. Stone has designed a novel type of compound wire, which he describes in a recent patent.

The manner of suppressing the evil effects of capacity involves giving the circuit suitable inductance. For the purpose of increasing the inductance of a conductor, Mr. Stone surrounds the wire with a cylinder of paramagnetic material, such as iron, M, Figs. 1 and 2, but in order to prevent the current from flowing along the surface of this iron cylinder, the inventor separates the iron cylinder from the copper core, C, by an insulating coating or film D. The resistance of this coating or film, owing to the longitudinal discontinuities of the sheath, need not be great. In fact, if the longitudinal discontinuities be sufficiently frequent a mere coating of the oxides of the metals will suffice. Further, in order to prevent the iron sheath from unduly increasing the effective electrostatic capacity of the circuit and for other reasons, Mr. Stone makes the iron cylinder discontinuous longitudinally.

The presence of one conductor in the neighborhood of another necessarily increases the electrostatic capacity of the latter, and to that extent the iron sheath surrounding the copper core increases the electrostatic capacity of the latter, but if the longitudinal sections be sufficiently small this increase in capacity will be the only resulting increase in capacity experienced. As far as this feature is concerned it is sufficient to make the longitudinal sections small compared to one-half of the wave-length of the electric current transmitted over the circuit. This latter condition is imposed by the fact that if the longitudinal sections of the sheath be as great or greater than one-half of the wave-length of the electric current to be transmitted over the core the individual sections of the sheath will have different portions simultaneously subjected to the extreme differences of potential of the positive and negative maxima of the waves, the effect of which on the current would be that of a spurious increase of electrostatic capacity.

The other conditions which demand the division of the sheath into relatively short longitudinal sections are relative to the prevention of the current from passing to the surface of the sheath, as already described, and these conditions are therefore closely allied with the insulation between the sheath and the core.

In order to prevent the current from passing to the sheath at one end of a section and returning to the core at the other end of the section, it is only necessary to make the impedance of the path via the sheath greater than that via the core. Of course this could be done with scarcely any film of high-resistance material between the core and the sheath if the sections were made sufficiently short, and it is advisable to make the longitudinal sections sufficiently short to materially assist in the operation of preventing the current from passing to the sheath.

TELEPHONE WAR AT KEOKUK, IA,

A dispatch from Keokuk says: Competition fierce and uncompromising in the telephone business is just at present playing havoc with the people of Keokuk and with the warring companies. The competitors for public patronage are the Iowa Telephone Company and the Mississippi Valley Telephone Company. The latter is a new concern, and its owner is J. C. Hubinger, a wealthy citizen of this town. Some time ago Mr. Hubinger opened a telephone exchange and cut the price in two. It was believed that he could drive the old company out of town, but thus far he has failed. The people hailed his advent with joy, but they discovered that when theory was put into practice theory was not always carried out. They found that to get complete service they were compelled to have both telephones in their houses, and thus paid the old price. But this was not all. The rival's wires are always crossing one another, and subscribers are always talking to people they don't desire to converse with. Then the two bells sound so much alike that one never knows what telephone is used. The old telephone company has evinced no disposition to buy the newcomer's plant, and the war rages with unspeakable dissatisfaction to all parties concerned. Mr. Hubinger is the proprietor of the electric light and power plant and of the street car lines of Keokuk. He intends to carry his telephone war into Burlington, Davenport, Quincy and Kansas City.

BELL TELEPHONE vs. WESTERN UNION IN NEW ENGLAND.

No better example of the competition the Western Union Telegraph Company is meeting from the American Bell Telephone Company can be found than the situation in and around Boston. It is not generally known that the New England Telephone Company is catering for local messages, which business has been exclusively within the control of the telegraph companies, but such is the fact. One can now call a pay station office in any of the Boston suburbs, and dictate a message over the telephone to the operator in charge, and the message will be delivered for fifteen to twenty-five cents, according to distance. The New England Telephone Company has had blanks prepared, similar to those used for telegrams, with a printed contract on same, for delivering such messages. It costs twenty-five cents to send a telegram limited to ten words, but there is no such limitation clause in the New England Telephone contract, and there are no such delays as in the case of telegrams, while the sender of such a dispatch by telephone can usually get a very prompt response.—Boston News Bureau.

PENALIZING DELAY OF A TELEPHONE MESSAGE.

A dispatch from Hopkinsville, Tenn., of March 15 says: Rev. J. C. Graves, a minister of this city, who recently brought suit against the Cumberland Telephone and Telegraph Company for damages for failure to promptly deliver a message, had his case decided in his favor in the Christian Circuit Court today, when a verdict for $50 damages was given him. It is the first case against the telephone company ever brought in court here, and the verdict was awaited with unusual interest.

THE AMERICAN BELL TELEPHONE net gain in instruments was 800 in the month ending February 20, and 1,199 since December 21.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—III.

BY JOSEPH APPLETON.

(*Copyright*, 1897.)

APPLICATION AND USES IN GENERAL.

BROADLY speaking, the use of a storage battery is to accumulate electrical energy, when it can be generated cheaply, and to give it out at a time or place when the conditions are such that to produce it would be expensive or impossible. We will consider generally, in this chapter, the applications of the storage battery to various engineering problems, and later examine each in detail.

To obtain the best results with storage batteries in any service, one point must be rigidly observed, that is, to employ the proper type of cell for the work to be performed. In the early days of storage battery work this was ignored and many of the failures which have been recorded are traceable to this account.

In other branches of engineering infinite time and skill are expended in considering and selecting the type of apparatus most suited to the conditions. For example, high speed engines will not work efficiently at slow speed, and slow speed engines cannot be run at high speed, neither is each type equally suited to all conditions of service where efficiency and economy are properly considered. It is needless to mention more instances of this, yet in spite of the universal recognition of this principle in general engineering work, in the case of storage batteries, the general practice was to ignore it, and to consider a storage battery simply as a piece of apparatus to store up electrical energy, for any purpose, irrespective of the character of the work, the classification being nothing more than good, bad and indifferent, with very little of the first.

Modern practice has, however, changed this and it is at last understood that there are many types of cell, and that a cell which can run a phonograph, need not of necessity be the one which should be used for regulation on a trolley road; in fact, it is just as necessary to use the proper type of storage battery for the work to be performed as it is to employ the most suitable machinery for the conditions which govern the generating portion of the plant.

In isolated plants a storage battery performs the following functions:

1. To store up surplus energy, thereby keeping the plant operating at the most economical load.
2. To supply current when the generating plant is shut down.
3. To act as a regulator and a reservoir.

Take, for example, a plant in an office building or large dry goods store. A sufficient capacity in generating machinery must be kept in readiness to supply the maximum demand; this demand varies according to the conditions of the weather, state of business and other causes which are entirely outside the control of the engineer, who, in fact, receives no warning before his load is increased and sometimes doubled. Where a storage battery is installed the conditions are very different; less machinery is required and that which is used can be operated practically at full load and consequent maximum efficiency, the surplus energy over actual requirement being used for charging the battery. In the event of any increase in load, the current used for charging the battery is available, and in addition to this the battery will discharge and take care of a portion of the extra load. The amount of surplus energy thus stored up during the operation of the generating plant can be used to carry the load after the machinery is shut down.

It is found from actual experience, that where a storage battery is used in this way the fuel consumption is no more than when sufficient generating machinery is kept in readiness to meet any emergency, and therefore the energy stored during the day and used for carrying the load after the plant is shut down costs practically nothing.

Again where electric elevators are used, and they are coming into use more and more every day, a storage battery is an indispensable part of the equipment. The elevator takes from three to four times the energy to start that it takes to hoist, and this has to be provided for in the generating machinery, unless a battery is used. It is also impossible to operate elevators and furnish current to incandescent lamps from the same generator without a storage battery, as the fluctuations due to the starting of the elevator cause the lamps to burn unsteadily. In a plant of this description a storage battery of suitable capacity will reduce the generating machinery required about one-third, and, moreover, effect a great saving in operating expenses.

A different class of isolated plant is found in residence lighting, especially in country and suburban districts. Here the motive power may be either steam, water, gas or oil, the storage battery being used chiefly as a reservoir. The generating plant is run two or three times a week, or oftener, to charge the battery, the current for lighting being drawn entirely from the battery, except on special occasions, when all the lights are required and the total capacity of both generating plant and battery is needed. This is one of the cheapest possible methods of producing electricity, especially where water, gas, or oil is used as the motive power.

It is not generally known that by using a gas engine to run a dynamo three times the amount of light can be obtained from electric incandescent lamps than would be given by burning the gas direct. This is due to the fact that the gas contains more energy in the form of heat than illuminating power. An oil engine compares very favorably in cost with a gas engine, the cost per horse-power hour being a little less. Numerous instances where this class of installation is in successful operation will be given later.

While dealing with the question of isolated plants, it may be well to refer to a method of utilizing storage batteries which has repeatedly been put before the public in flattering terms; that is, to the delivery of electricity stored in batteries to consumers, in the same way that groceries and milk are delivered. This sounds very enticing and easy, but from the commercial point of view it is absurd, as the cost of hauling around the full and empty batteries, together with the contingent expenses of handling, greatly exceeds the cost of distributing electricity from a central station by means of conductors, while the cost of generating the current is practically the same in both cases, if anything favoring the direct distribution method.

In direct current central lighting stations, there are six ways in which storage batteries can be used to advantage, the relative value of each method depending on the conditions which obtain.

1. To carry the peak of the load.
2. To carry the entire load during periods of light demands.
3. To regulate pressure on the system.
4. To absorb surplus energy.
5. To act as a reservoir.
6. In sub-stations which form centers of distribution for sections which are too far away from the main station to be reached economically by the ordinary system.

In all central stations which generate current for lighting purposes, the maximum demand occurs only for about two hours out of the twenty-four. This means that sufficient generating machinery must be installed to take care of the maximum load or peak; yet probably 50 per cent. of the same is used only for from two to three hours a day, and the remainder of the time lying idle and unprofitable. By the use of a storage battery, which can be discharged at high rates for two or three hours and can take care of the maximum demand or peak, sufficient generating machinery need be installed to provide only for the balance of the load, together with the current required for charging the battery.

The battery can be charged when the load is light, thus utilizing the generators when they would otherwise be idle. In this way the load curve on the generators, during the twenty-four hours approaches more nearly the straight line, which is the aim of all central station managers, and ensures the most efficient operation of the plant. Central stations which were designed and constructed without a storage battery equipment can increase their capacity by installing a storage battery, the cost per kilowatt being less than that for a generating plant.

This feature of carrying the peak is only one of the uses to which a storage battery can be put in central stations and, although, perhaps, the most prominent, yet in addition a properly designed storage battery equipment makes the whole system very flexible and enables economies to be effected which would be impossible without the use of a battery.

This question will be dealt with fully in a later article, and examples given, showing how a storage battery can be used to advantage in direct current central stations.

The problem of reducing the cost of electrical energy to the lowest possible figure is one which confronts all electric light and power companies. Selling prices have to be reduced to meet competition and secure new business, yet dividends must be earned and paid to the stockholders who are generally ignorant of the business and look upon it purely from a money-making point of view.

The efficiency of generating machinery has been gradually increased till there is not a great deal of room for improvement in this direction, consequently the question of cheaper power and of fuel economy is the one which attracts most attention. Modern practice is tending toward the location of large generating plants where cost of production is the lowest the electricity being transmitted to centers of distribution. The generating plant is usually located in the spot most advantageous for generating and not necessarily for distribution. This location is generally on a water front, where real estate is cheap, water plentiful and coal easily obtainable. In order, therefore, to obtain the fullest economy, the cost of transmitting the electrical energy to the centers of distribution must be so reduced as not to offset the saving effected by cheap generating facilities.

Transmission over long distances by means of direct currents, at low tension, is too costly on account of the large investment in copper required, and direct current transmission at high tension is impractical on account of the difficulties in constructing and operating direct current generators and transformers at a sufficient voltage to reduce the copper investment to a point which is commercially practical.

The solution of this problem lies in the use of alternating current generators for producing the energy which can be safely and economically transmitted over long distances and converted into direct current for distribution by means of rotary transformers and storage batteries. This system appears to be the most perfect method at present of utilizing cheap power obtained from water, where available, or from steam, where the cost of production can be reduced on account of special facilities. Examples of this system will be illustrated and described later on.

In electric railway work there are two methods of utilizing storage batteries. First, where the battery is stationary and acts as an auxiliary to the generating plant. Second, where the battery is carried on the car or locomotive and supplies the current for its propulsion.

In the application of storage batteries to the first or stationary method, there are two distinct ways of utilizing them.

First: In the power house to equalize the load on the generators and to maintain a constant pressure on the system.

Second: At the end of the long feeders to maintain a good pressure on the section under all conditions with an economical investment in copper.

In both of the above cases the battery will also assist the generating plant during the peak or time of maximum load. The application of storage batteries in the power house is better suited to smaller roads where comparatively few cars are operated and the load on the generating plant is much more fluctuating than on a large system where many cars are operated and the fluctuations, due to the starting and stopping of the cars, are felt in a much less degree on account of the number of cars in operation, being averaged or distributed over the whole number.

A storage battery in this case will discharge during times of heavy load, and store up energy during periods of light load, thus reducing the capacity of the generating plant required and enabling that which is in operation to work at a constant and economical point; in addition, the battery is of great service in protecting the machinery from sudden and severe strains due to the large portion of the load being thrown on or off.

Where batteries are placed at the end of a long feeder they act as a reservoir and equalizer, giving out current when the load on that section is greater than the capacity of the feeder and storing up energy when the demand is less than the capacity of the feeder. In other words, a storage battery enables the section to be operated with a feeder capable of carrying the average current, instead of the maximum, besides maintaining the pressure as steady as in the power house. Examples of these methods will be given later on with figures showing results obtained and saving effected.

There is probably no greater field for the use of storage batteries than in connection with railway work on these lines. Managers and engineers have been sceptical and have not realized the fact that storage batteries properly applied are a much more profitable investment than additional copper, which, like generating machinery, pays for itself only when fully loaded, whereas storage batteries enable both generating machinery and feeders to be operated at maximum efficiency, thereby giving the greatest return on the investment.

The second method, where the batteries are carried on the cars or locomotives, is still more or less in the experimental stage. Numerous trials have been made with satisfactory results, yet at the present time this system has not proved its commercial value sufficiently to become a serious competitor to the other systems of electricity as applied to railway work.

At the present time a road in Chicago is being equipped entirely with storage battery cars, every detail from the track upwards being designed and constructed especially for the purpose of getting the best results from this system. This work is attracting great attention among electrical railway men, and the results will be eagerly watched.

Recently the attention of the public has been drawn to the question of horseless or motor vehicles, and those operated by electricity seem to be the most practical and likely to attain commercial success. There is an entire absence of smell, noise and danger which, to a certain extent, must of necessity accompany all vehicles operated by explosive or heat motors. In addition to this there is no doubt that electrically propelled vehicles can be operated and controlled with greater ease and accuracy than other types and their operation is dependent entirely on the storage battery which provides the motive power. It is not probable that these motor vehicles will replace the horse for some time to come, yet there is undoubtedly a large field for them if arrangements are made to recharge the batteries without trouble to the user; this of course is purely a matter of organization.

An article will be devoted to the consideration of this subject, in which the details of construction and results obtained will be fully described.

Launches propelled by electricity are very popular for pleasure purposes, the current being obtained from storage batteries carried under the seats and in the bottom of the boat. The chief advantage of electric propulsion for this purpose is the entire absence of smell and noise, together with the small amount of attention required to operate the launch.

In telegraph and telephone work storage batteries have replaced gravity cells to a large extent, the cost of maintenance being reduced to less than one half. In this and similar service, such as fire alarm and signal work, the use of storage batteries is very successful, their voltage and internal resistance being better adapted for the work than that of primary cells.

Train lighting by electricity is undoubtedly the most satisfactory method yet devised and naturally storage batteries must play an important part in this work.

There are numerous other uses for storage batteries in profitable form where small quantities of electrical energy are required at intermittent periods. Among these, the following may be specially mentioned: Cauteries and lamps for medical purposes; dental engines and mallets; phonographs, kinetoscopes and similar apparatus; lamps for carriages, bicycles, etc.; electric fans, sewing machines; X-ray outfits, and a multitude of similar purposes.

LEGISLATION IN CONNECTICUT AGAINST THEFT OF ELECTRIC CURRENT.

WE give below the full text of a bill which is going through the Connecticut Legislature to prevent theft of electric current and has already passed the House of Representatives, after being reported favorably by the Committee on the Judiciary:

AN ACT CONCERNING THE PUNISHMENT OF PERSONS STEALING ELECTRICITY.

General Assembly, January Session, A. D. 1897.

Be it enacted by the Senate and House of Representatives in General Assembly convened:

Section 1. Any person who has no contract, agreement, license, or permission, oral or written, with or from any person or corporation authorized to manufacture, sell, or use electricity for the purpose of light, heat, or power, or with or from any authorized agent of such person or corporation, for the use of the electric current belonging to any of said persons or corporations, who shall knowingly withdraw or cause to be withdrawn in any manner, and appropriate to himself, such current from the wires of any of said persons or corporations for his own use, or for the use of any other person or corporation, shall be punished by a fine not exceeding fifty dollars, or by imprisonment in the county jail not more than ninety days, or both; and any person who shall knowingly assist such other person in such withdrawing and appropriating such current from such wires, to the use of such other person, or to the use of any other person or corporation, shall be punished by a fine not exceeding fifty dollars, or by imprisonment in the county jail not more than ninety days, or both.

Sec. 2. Any person who has a contract, agreement, license, or permission, oral or written, with or from any person or corporation authorized to manufacture, sell, or use electricity for the purpose of light, heat, or power, or with or from any authorized agent of the same, for the use of the electric current belonging to any of said persons or corporations, for certain specified purposes, who shall knowingly, willfully, and intentionally withdraw, or cause to be withdrawn in any manner, and appropriate to his own use, or to the use of any other person or corporation, such electric current, from the wires of any of said persons or corporations, for purposes other than those specified, shall be punished by a fine not exceeding fifty dollars, or by imprisonment in the county jail not more than ninety days, or both; and any such person to whom such electric current is furnished, from or by means of a meter, who shall willfully and with intent to cheat and defraud any of said persons or corporations, alter or interfere with such meter, or by any contrivance whatsoever, withdraw or take off the electric current in any manner, except through such meter, shall be punished by a fine not exceeding fifty dollars, or by imprisonment in the county jail not more than ninety days, or both.

BURGLARIZING SAFES BY ELECTRIC HEAT.—IS IT FEASIBLE?

DURING the past month or two the columns of The Electrical Engineer have contained frequent references to the alleged new danger threatening the inviolability of safes, in the shape of the electric arc, by means of which, it is claimed, holes are bored in the stoutest safes in a few minutes, and all wonted precautions are frustrated. If this were true, it would, of course, have its serious meaning for safe makers, burglar alarm companies, and bankers, but it is obvious that the electrician is also closely concerned. The great argument that has been put forward is that the now almost universal use of electricity places within reach of the burglar the immediate supply of current that he needs, so that all he has to do is to hitch on his wires and his boring stick of carbon and melt his way through the thick ribs of steel as easily as though he were sampling cheese with an ordinary groceryman's gouge. Describing the operation in our issue of Feb. 24, Lieut. S. Rodman, Jr., said with regard to certain sensational experiments in Chicago:

"As a matter of fact the experiment under discussion was not made in a laboratory but under exactly the same conditions which in practice would exist and might be made use of by an unscrupulous person for a surreptitious purpose. That is, flexible wires were connected to electric light mains and under the sidewalk—the same as could be done in any city—and led to the safe which was pierced. One wire was connected to the safe and the other having a suitable resistance in circuit was connected to a carbon electrode. The remainder of the operation—that is, the burning of a hole through the safe—is so simple that I have seen persons who have had little or no knowledge of electricity do it with perfect ease almost the very first time. * * * * The operation of burning holes through safes by the use of the electric current such as can be drawn from an electric light main or a trolley wire, is a perfectly practical and feasible operation, and it is one which many bankers to my knowledge have investigated. The result is that any safe or vault, no matter how thick, can be readily and quickly pierced, consequently there is no security whatever in safes and vaults by themselves. They must be protected and the most practical and economical method which suggests itself is that of electrical protection."

Now, bankers say that if these reports were trustworthy, then they have no further use for electricity in their bank buildings, but would exclude it; and they add that they would make it their business to drive away exterior circuits on the streets just as far as the law compels saloons to be separated from the school houses. The restriction of electrical growth and utilization thus implied is not to be idly dismissed. These Chicago tests have been put forward in connection with the exploitation of a new safe protective system, and might therefore be guardedly received, however legitimate the enterprise; but it is evident that data on this subject is not difficult to secure and that the new plan of burglarizing suggested may be found, when studied practically, to take its place among the possible impossibilities of which the electrical arts are already so full.

The tests reported show that with currents of from 50 to 80 volts and from 250 to 350 amperes, small holes have been bored through 3½-inch steel safe walls with the electric carbon boring tool in about three to five minutes. The business end of the carbon point pressed against the safe is concealed by a small hollow box lined with fire clay or asbestos, and a wooden handle is fastened to the other end by which it is pushed forward as the metal yields like wax. This sounds simple enough, but the actual doing in a practical way out in the hard, cold world, where the burglar has to work with a minimum of leisure and of facilities, is attended with enormous difficulties. We have already called attention in our pages to the opinion of Prof. Elihu Thomson, who is certainly the leading authority in the world on electric welding and metal melting. Prof. Thomson believes that there is no doubt whatever of the possibility of melting through masses of iron or steel of even considerable thickness, provided there is time enough to do it and sufficient current is available; but he thinks it very doubtful, whether any burglar could tap a lighting circuit and obtain the current required, which might range in the neighborhood of 200 to 300 amperes. He would not only need to tap the mains, but he would have to arrange a resistance in circuit so as to produce a stability in the arc formed; that is, he would have to cause a drop of a certain number of volts between the constant potential mains and the arc produced and get rid thereby of a considerable amount of energy. Prof. Thomson does not think that he could, with much less than the current stated, melt into the iron or steel at a rate sufficient to be of much effect in a reasonable time. Furthermore, the use of such an affair produces an intense light and radiant heat, which demands ventilation, particularly as vicious fumes are given out besides. This would seem to make it impossible for work to be done in a restricted space and it certainly could not be accomplished without attracting notice on account of the glare and fitful light, unless very effective screening were used to prevent the light from getting out through windows and attracting attention. To put it in another way, Prof. Thomson thinks the paraphernalia which the burglar would have to carry along and have at his disposal for the attempted work would be a sufficient discouragement in itself, while the time required and the risk of discovery would be so great as to remove the operation from among the possibilities, except under very exceptional circumstances.

Another distinguished authority is Mr. J. J. Wood, the electrician and general superintendent of the Fort Wayne Electric Corporation, who says: "Immediately after the appearance of the article in the newspapers, we made some experiments at this factory to determine the feasibility of the plan, and found that it would require much more current than could be conveniently drawn from the circuits. In addition to which, special regulating devices had to be employed in order to keep the current at a suitable voltage for the work. During the experiment, the light was so intense that the parties performing it, including myself, burned their eyes very badly; while the fumes given off required the best possible ventilation for their removal."

Mr. C. O. Mailloux, the consulting electrical engineer of this city, whose work for the Astor and Vanderbilt estates is well known, and who has probably supervised more bank installations than any other man, has kindly gone into the question very thoroughly for us, and his analysis of the matter is here given:

"Replying to your query as to the possible rôle that electricity might be made to play in facilitating the work of the modern 'scientific' bank burglar, I would state at the outset that I cannot pretend to do anything more than to give an idea of the limitations of the electrical current supply that is likely to be available for burglary purposes. These limitations appear to me to be such as to make the possibilities of any new departure in burglar methods involving the use of electricity of much more limited application and practicability than might at first be supposed.

"It takes a certain amount of energy in the form of heat to fuse, volatilize, burn up, or otherwise dispose of a given quantity of material. I have no data on which to base any exact calculations as to the quantity of electrical current required to burn a hole of given size through metal plates of various thicknesses, but there is probably a definite relation between the quantity of material melted and the quantity of current used. This quantity might be expressed in calories, or heat-units, or it might be expressed in the more convenient electrical unit of coulombs or ampere hours or minutes, per cubic centimeter or per cubic inch, or some other convenient unit or ratio. It would be more practical in this case to take the current (ampere-hours), than the watts (watt-hours), because the watts will depend upon the proportion of energy expended in resistance extraneous to that portion of the circuit where the work is to be done. In the electric arc, for instance, a considerable proportion of the energy is expended in overcoming the resistance between the two carbons, and a much smaller proportion is expended in burning the carbons themselves.

"In the case of the street lighting arc lamp, the consumption of positive carbon goes on at a rate varying between two and four ampere hours per cubic centimeter. Iron or steel may be from four to six times less refractory than carbon, and may therefore require a proportionately reduced current consumption. Allowing, for instance, about ½ ampere hour, or thirty ampere minutes, per cubic centimeter of plate, then we can form a rough idea of the quantity of energy that would likely be required to perforate a safe plate having a thickness of from six to fifteen inches. It requires a certain nicety of judgment on the part of the burglar to determine what size hole he shall 'bore.' With an ordinary arc light carbon, he could scarcely hope to increase the current density above 20 or 25 amperes, unless he is prepared to work with red-hot carbons. With larger carbons, on the other hand, the hole would have to be bigger and the quantity of energy required would increase.

"If, instead of boring the hole through by means of the arc, Mr. Burglar were to attempt to do so by melting a portion of the plate between two contact points, on the principle of an electric welding heat, there would still be the same relation between the coulombs of current (not the watts) and the volume of metal to be disposed of, and the time required would depend entirely on the current density that could be maintained through such electrodes as might be used for passing the current through the portion that is to be burned out. The size of opening of bore desired in this case would also influence the amount of energy and the time required for the operation.

"As the burglar is necessarily compelled to do his work in the shortest possible space of time, it is necessary for him that he shall use the largest possible current densities. To produce a hole having an average area of one square inch through six or seven inches of plate, the current would have to remove from 100 to 125 cubic centimeters of metal. This would likely require at least 2,500 to 3,000 ampere minutes of current. If the work is to be done in, say, ten minutes, the current must be used at the rate of 250 to 300 amperes. If the plates are thicker, of if the 'hole' must be larger, the quantity of current required will correspondingly increase. With the present systems of interior wiring, it would be difficult for the burglar, except by the purest accident, to find any circuit, to draw his current supply from, that would be able to furnish even half that output of current, without causing the safety fuses or automatic cut-outs, or other safety circuit-breaking appliances to operate so as to open the circuit and cut off the current supply altogether. It must be remembered that the circuits which supply current to the electric light outlets are usually limited to something like ten amperes; and even allowing for the eccentric and erratic fusing point of the fuse, it is doubtful if a current supply of more than thirty amperes could be depended upon for a period even as long as ten minutes; while in all cases where the fuses are made of tested wires, the circuit would probably be opened by the safety fuse in much less time, and by a much lower current. If, perchance, the burglar could obtain access to a cut-out box, and could thus be enabled to make direct connection with some feeder or main conveying the current to this point direct from the source, whether said source be an isolated plant or the (Edison or other) street mains, it would still even then be doubtful if he could depend upon a sufficient supply of current for effecting his purpose.

"The most approved practice of the last four or five years has been in the direction of relatively minute sub-division and individualization of the lighting circuits. In the early days of electric lighting,, it was not uncommon to run a vertical riser from the cellar to the top story, and to connect with this vertical riser at all the floors. In such a case as that it might be possible that the safety fuse protecting the main at the particular floor on which the burglar is operating might allow a current load of two or three times the amount of current actually required for that particular floor. The safety fuse supplying the vertical riser would not be expected, of course, to operate until the total load on the vertical riser had reached the limiting point. With the present system of wiring, however, the sub-division of load on individual feeders or mains, is such that it is seldom that the load on an individual feeder exceeds 125 to 150 amperes, while in the majority of cases, the load is scarcely over 100 amperes. It can readily be seen, therefore, that under those conditions, even assuming the safety cut-out to be adjusted for a considerable increase above the normal load of said feeder or main, the burglar could scarcely count on even as much as 200 amperes before causing the safety cut-out to operate so as to cut off the entire current supply. The possibility of the burglar so drawing his current supply direct from a feeder or main is remote for the reason that in most, if not all, cases, the cut-out cabinets are located in corridors, or in other public portions of the building, where they would be more or less distant from the bank vaults; which circumstance not only increases the difficulty of bringing the current supply to the point where it is to be utilized by the burglar, but also increases the chances of his being detected while he is doing his work. If, then, he has nothing to depend upon but an ordinary fixture connection, or lighting circuit, he cannot hope to get a current much greater than 20 to 30 amperes before his current supply becomes cut off, while if the circuit work is properly designed, and the fuses are as they should be, his current supply will more than likely be cut off by the time he has drawn 15 amperes for a minute or less.

"If the system of current supply is one utilizing the alternating current, it is possible that a converter might be used which would transform the electrical energy from the line potential (say 110 to 115 volts), to a lower potential (10 to 20 volts), such as used in electric welding. The same thing could also be done with a direct current by using motor dynamo or rotary transformers; but we must bear in mind the fact that these appliances are more or less bulky and heavy, and that they cannot, consequently, be carried in the burglar's satchel with the rest of his tools, while, at the same time, they require more or less skill and experience for their proper handling.

"In conclusion, my opinion is that while the 'trick' or 'scheme' is theoretically possible, there are so many elements of uncertainty and so many contingencies likely to frustrate it, that it does not seem to me at all likely that we shall hear of many bank safe burglaries which have been rendered possible, or which have been effected, by the aid of electricity in any such manner as outlined in your query."

These three weighty comments bring up points enough to throw entire discredit on the whole idea, but we may venture to supplement them with a few other comments. It will be noted that the smallest current spoken of as necessary is, say, 350 amperes at 50 volts, or not far short of 25 horse power. Mr. Mailloux has shown the conditions against which the burglar would have to contend everywhere in getting that current in a building. But Lieut. Rodman has suggested that the burglar can use a storage battery. So he can, but he would need a room to place the cells in and facilities for running wires to them and from them, and it may be doubted whether he could get along with less than a ton or two, or even more, as enormous capacity for quick and heavy discharge of the current would be needed. The suggestion has also been made that the live current from the line in the building or outside could be immediately converted to its necessary conditions by means of a rotary transformer; but such a transformer unit of from 15 to 25 horse power would weigh complete, between three and five tons, and the burglar would be even less likely to carry that around in his kit than the storage batteries.

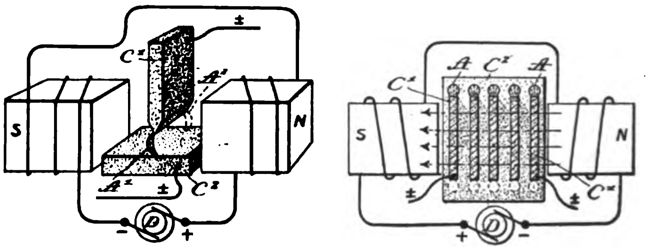
The proposition to go outside the bank building for the current is one that could hardly be seriously meant, if the plan involved is that of attachment to aerial circuits; but Lieut. Rodman says that "the electrician can readily see that with proper manipulation the trolley system may also be made use of." Our readers are tolerably familiar with such work, and we would like to ask them what freedom from detection they would expect while making a 25-horse-power connection to an exposed, overhead electric light or trolley circuit, and while running it afterwards into an adjacent bank building? How would they do the work in such a way that nobody would see them or interfere with them and nobody would after it was done find out its existence? There are some things more preposterous than others, and this seems to be among them.

Nothing has been said so far with direct emphasis on the necessity the burglar would be under of knowing what current he was working with. Prof. Thomson has referred to the necessary use of a resistance, supposing the burglar had no batteries or no direct current transformer. Most buildings are wired on the low potential direct current 220 volt system, and it is doubtful whether a large amount of current could be taken from one side of a 3-wire system without its being noticed, especially if the unbalancing occurred in the night time and was of a sort of fitful character. The arc which does the melting requires only about 50 volts, and if 200 amperes were used on the 220-volt circuit, it will readily be seen that something like 160 to 170 volts might be required to be lost, or taken up, in resistance, or about 45 horse power! Can any one imagine the burglar dealing successfully with such conditions and without further encumbrances in the shape of heavy resistances, regulators, measuring instruments, etc.? Moreover, in this review of the subject, which could be gone into further, if space permitted, it has been assumed that all the burglar has to do is to take his supper and sit down quietly to his job on the safe. We have assumed that the bank employs no burglar alarms, no watchman, no bull dogs, that there are no police or janitors, and that the safe stands out on the floor as readily accessible as the ice water filter. It is to be assumed that banks are fairly careful in these respects; but even if they were not we should feel inclined to back a good modern safe against the electrical burglar unless he came far better prepared than any investigation yet made, or any proof yet produced, shows him to be.

In view of the able expert testimony we have gathered on this subject, we have no hesitation in advancing the opinion that bankers and other guardians of funds and securities need lose no sleep worrying over a possible burglary by electrical means. We would further suggest that if such sensational methods are resorted to in order to exploit a new system of electrical protection, it would be well for bankers to examine carefully into the merits of this system before placing extra confidence in it. In our mind a watchman and a couple of bulldogs would be a more conservative investment, at least until this system has been demonstrated to possess the merits claimed for it.

PATTEN'S CARBIDE OF CALCIUM ELECTRIC BLOW-PIPE FURNACE.

It is well known that an electric arc will blow or move out of a magnetic field if free to do so and in a definite direction determined by the direction of the lines of force. Thus in Fig. 1, where C' represents an upright slab of carbon placed at arcing distance from the horizontal carbon slab C^2, and N S are the poles of an electromagnet, so placed that the arc between the electrodes is normally in the field of the magnet of which the lines of force flow from N to S, then the arc between carbons will assume a position dependent upon the direction of current flow and the lines of force. Thus if the lines of force have the direction N to S and the current flows from the upper to the lower carbon then the arc will assume the position A' at the left-hand corner of the upright carbon slab. Now if either the current should change direction or the magnetic field should reverse then in either case the arc would pass over to the right-hand edge or corner of the upper carbon slab, assuming the position A^2. In these physical conditions there-



FIGS. 1 AND 2.

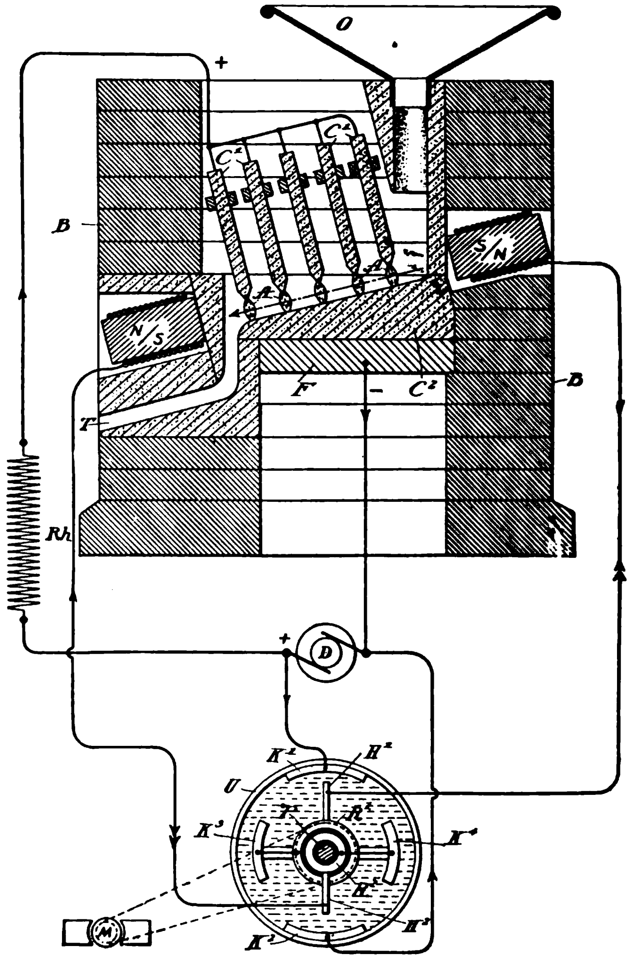


FIG. 3.—PATTEN'S ELECTRIC BLOW PIPE CARBIDE FURNACE.

fore, lies the possibility of moving the arc to and fro across the edge of the upper carbon slab.

Fig. 2 shows an arrangement of a number of upright parallel electrodes placed in juxtaposition to a carbon slab forming the other electrode. The several arcs in such case between upper and lower electrodes traverse back and forth from side to side of the upper carbon with each alternation of current, and material passed between the upper and lower carbons on the lower carbon slab is attacked by the electric arcs A A in rapid succession as they vibrate to and fro over the passing material.

Based upon this principle of the electric blow-pipe, Mr. F. J. Patten, of New York, has designed and recently patented a most ingenious furnace for the production of carbide of calcium and similar products.

Our engraving, Fig. 3, shows in cross-sectional elevation a furnace constructed on the plan of using a continuous current between the electrodes and an alternating field. The lower electrode C^2 is given a slanting position, so that the material between electrodes will slide, or flow down, its surface from right to left while the arcs between the several upper electrodes and the lower one are traversing back and forth from one side of the magnetic field N S to the other, thus maintaining practically a sheet of electric flame, through which the material must pass.

F is an iron slab on which the lower carbon electrode C^2 rests, and to which one terminal of the working circuit is attached, C' C' are the upper carbon electrodes, all attached to the other working-circuit terminal, and N S are the poles of an electromagnet. O indicates a hopper through which the material to be fused is admitted, and T a draw-off tube from which the material when in the liquid or molten form is taken from the furnace.

Of course, it will be understood that the current must not reverse too rapidly in the system shown, but should have a comparatively slow period or rate of movement, preferably much slower than the period or rate of ordinary alternating currents as used for lighting. It is also a ready inference that if the current between electrodes be direct and the magnetic field be reversed in order to move the arc, then this magnetic reversal should also be comparatively slow; otherwise excessive heating and loss of energy would be the consequence.

This is accomplished as follows: A direct-current dynamo D supplies the continuous direct current sent through the electrodesC' C' and C^2 of the furnace. A shunt-circuit taken from the brushes of the dynamo D is led to the two plates of conducting material K' K^2 of the liquid current-reverser shown at the bottom of the figure. This is a current-reverser of special form adapted to reverse currents of considerable strength without sparking or rupture of the circuit.

The circular part U represents in horizontal projection a vessel. At its center is a spindle P, that carries an arm at the extremities of which are two other conducting plates K^3 K^4, which, revolving with the spindle P, driven by the motor M, thus pass the fixed plates K' K^2 each half revolution.

The revolving plates are connected each to an insulated sliding-ring contact R' R^2, on which brushes H' H^2 bear, and as a result of the rotation of the plates K^3 K^4 a slowly-reversing alternating current is delivered to the circuit that includes the windings of the electromagnet N S S N, the magnetism of which is thus slowly reversed, causing the arc between the electrodes C' C' and C^2 to be traversed back and forth with the changing magnetism. Thus there is a direct-current system throughout, with slowly-reversing magnetism in this last form.

AN ELECTRIC SEWING MACHINE.

A Chicagoan, Mr. John S. Biggar, has patented an electrically operated sewing machine. It is very simple in its construction and is adapted to be driven by a battery current. The needle is mounted upon the lower end of a core which is reciprocated by a pair of solenoids. A motor is contained within the frame of the machine and rotates the shuttle shaft. The solenoids and motor are placed in a common circuit controlled by a switch mounted on the frame of the machine. By this construction all the working parts are inclosed, thus eliminating all danger from handling by the uninitiated.

MR. NIKOLA TESLA will deliver a brief address, it is stated, at the annual exhibition of the New York Academy of Sciences, at the American Museum of Natural History, on Tuesday evening, April 6. His subject will be: "The Streams of Lenard and Röentgen, with Novel Apparatus for their Production."

DEAD WIRE IN ARMATURES.

BY R. PFUND.

REFERRING to Prof. Anthony's article on "Dead Wire on Armatures" in The Engineer, issue of Feb. 24, I find that I have made an error in giving the direction of the induced e. m. f. in the wire A in Fig. 2, in my article in the issue of Feb. 10. I should have said that when the lines of force are shot over the wire, the induced e. m. f. or current would be toward the observer, and in the opposite direction if they pass under the wire. I cannot, however, agree with Prof. Anthony that, under the conditions named, no e. m. f. will be developed in the wire in the position, shown in Figs. 2 and 4, but that one will be developed in the position shown in Fig. 3. On the contrary, an e. m. f. will be developed in any position of the wire except that shown in Fig. 3. The accompanying diagrams, representing the face and section of an electromagnet will, perhaps, make this clear. Let us assume also that instead of the lines of force around a wire being, not as usually represented, simply a series of concentric circles having a right or left-handed direction, according to the direction of the current, but that the flow of a current in a wire tends to rotate or strain the medium or atmosphere surrounding the wire; the rotation, or strain, being in a clockwise direction if the current flows away, and counter-clockwise if the current flows toward the observer, the amount of rotation or strain depending upon the strength of the current.

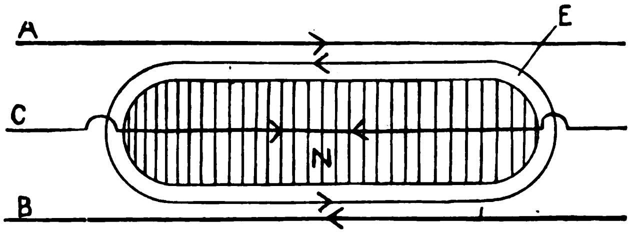

FIG. 1A.

Now, referring to Fig. 1A, E is the energizing coil. A and B are two wires stretched on each side, and C a wire stretched across the center of the face of the magnet. Suddenly charging the magnet so as to make the face a north pole will, according to the usual way of stating it, cause lines of force to come toward the observer, and will induce an e. m. f. in both A and B in the direction of the arrows; but none in C, because the strain is equal and in the same direction on both sides of C, as shown in Fig. 2A. For simplicity's sake, but a single stationary straight wire has been considered in the above diagrams, and in Figs. 2 and 3 of my former article; but, no matter where the return circuit comes in, no e. m. f. will be developed in that portion of the complete circuit, which has, like the wire in Fig. 3, an equal number of lines of force traveling in the same direction on each side, or, as shown above, is subjected to an equal and unidirectional strain on each side. Now, again, referring to Fig. 3, and assuming that the return circuit is directly opposite, facing my original straight wire, just as soon as this loop is turned around its axis out of its horizontal position, an opposite e. m. f. will be developed in each wire in accordance with the direction of the strain, and furthermore, the maximum e. m. f. will be developed with a given speed, while the position of this loop is changing from the horizontal to the perpendicular, because, assuming that the total strain is ten—five on each side of the plane of the loop, turning the loop through a certain number of degrees so as to make the strain six on one side, will leave but four on the other, and so on.

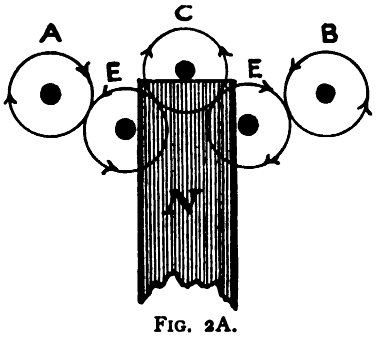

FIG. 2A.

Now, if the loop is in the perpendicular position, the entire strain will be on one side of each leg. Moving it through the same number of degrees as before will develop a very much weaker e. m. f., because it will not move far enough to materially reduce the strain on one side and increase it on the other. Even if it is moved a sufficient distance to transfer one entire assumed unit of strain to the other side of each leg of the loop, the effect will still be due to but one to nine.

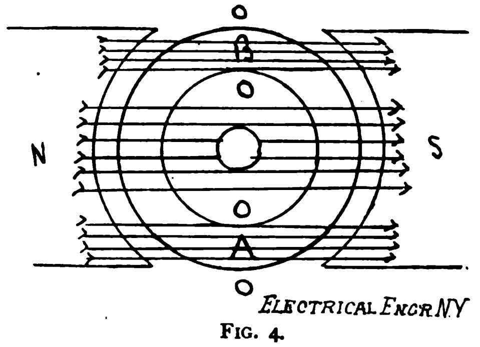

FIG. 4.

LETTERS TO THE EDITOR

THE CELLULOSE PRODUCT OF THE CORN-STALK.

I NOTICE in the last issue of The Electrical Engineer, page 317, a very uncomplimentary reference to the Marsden Company recently organized under the statutes of New Jersey with a capital of $50,000,000. The statement has never been made by any one competent to make it, or any one in connection with the company, that this was to be a sugar company, or that sugar was to be made electrically, or any other statement that would justify the article that you republish.

I desire to say for your information, and to enable you to intelligently correct the impression given by your publication, that this is an entirely legitimate business; that its object is to convert what has heretofore been largely or wholly a waste product and the largest waste product in the world, into commercial products of great value.

Mr. Marsden recently discovered that in the Indian corn-stalk was to be found the greatest body of practically pure cellulose in the world—cellulose of a higher grade in its natural state than that manufactured from cotton or wood pulp, costing anywhere from $500 to $1,000 per ton. Scientists have long recognized the value of a pure cellulose in the arts but its excessive cost has heretofore made its use limited only to cases where nothing but cellulose could be employed. But when we realize that this product of the corn-stalk has a world-wide market and can be utilized to the fullest extent that it can be produced, at many times the value of the corn, it will be readily seen that this feature of the discovery is of great importance.

One of the first uses made of this material was as a packing for the coffer-dams of warships, it having proven its superiority over any other material yet found. After a thorough trial made by the United States Naval Board, this material has been adopted by the Navy Department, and in the five warships now under process of construction, American corn-pith cellulose is specified, and we have no doubt of its universal adoption by all the leading navies of the world.

It has also proved to be the most perfect non-conductor known. In actual competitive tests, as a covering for steam pipes and boilers, it shows 27 per cent. better results than the best magnesia covering, and the same advantage when used in refrigeration. More than 150 different applications have been made of this material, with equally advantageous results.

From the foregoing, it will be seen that the cellulose of the Indian corn plant is destined to play an important part in the arts and manufactures of the world. This material is about one-half the bulk and one-eighth in weight of the corn-stalk.

When Mr. Marsden was requested by the Navy Department to furnish a quantity of this material for test, it was necessary for him to use several tons of corn-stalks in order to obtain a sufficient quantity. For this purpose he arranged a mill that cut the stalks into small pieces, and then by means of an attrition mill he ground the pieces into a fine meal. This product was taken from the mill by means of an air-blast, the difference in the specific gravity of the outside fibrous portion of the stalk and the inner portion, or pith, enabling the separation to be very successfully accomplished.

Upon an examination by Mr. Marsden of the fibrous portion of the stalk, he discovered that it was a valuable food for live stock. It was tested practically, and the cattle ate it with a relish. The matter was referred to Prof. H. J. Patterson, chemist of the Maryland Agricultural Experiment Station, College Park, Maryland, who made a thorough and exhaustive test of its value as a live-stock food, and I herewith enclose you a copy of an official bulletin issued by that station in December on the value of this new corn product.

When we realize that this heretofore waste product aggregated 160,000,000 tons per annum, which was practically a total waste, and that every particle of these stalks can be utilized to very great advantage—much more in value per ton than the corn crop—you can readily appreciate the importance of this discovery. The United States Government, after a very thorough investigation, have granted Mr. Marsden patents not only upon the product produced, but upon the method of manufacture as well. Patents have also been obtained in all corn growing countries throughout the world.

In addition to the advantages set forth, the statement has been made, based upon limited experiments, that the concentrated nutritious fibrous portion of the stalk, after the elimination of the pith and other impurities, contains saccharine, or cane sugar, in considerable quantities. Certain tests have been made, which indicate that the percentage is as great as in Louisiana sugar cane. Methods have not yet been devised for the extraction of this sugar. It is probably from this feature of the discovery that the erroneous impression has been stated that the company organized was a sugar company.

After the extraction of the saccharine matter, the fiber left is found to be a paper stock of greater value than wood pulp. When we consider that it is possible, therefore, from this same source, to produce all the paper that the country will require, its importance is still further enhanced.

The foregoing will give you some idea of the scope and possibilities of the Marsden Company, and why it is capitalized at $50,000,000, all of which we believe will be profitably employed both to the people who manage the enterprise, and to the country at large. We know of no development which can add so much to the commercial prosperity of the country at large, and the great farming districts of the West particularly, as this important discovery of Mr. Marsden, and we do not feel that any erroneous impressions or adverse criticisms are justified.

I have taken the trouble to write you quite fully on this subject, feeling personally that you do not intend to do us any injustice knowingly.

W. W. GIBBS,
President the Marsden Co.

Philadelphia, Pa.

THE DECISION ON HEATER SWITCHES.

WE note in your issue of Feb. 17, a communication from the Consolidated Company in regard to the recent decision on car heater switches and that you state that a copy of the decision was furnished you. By reference to that decision, you will note that the judge states that the element of the invention is contained in the necessary combination of an indicator with the switch for varying the heat supplied in the car. He says: "The novelty is in the combination and not in the separate elements." He also states that the defendant does not employ the same kind of an indicator or arrange his heaters in the same manner in which they were shown in the Dewey patent and also that the indicator is of a different type from that shown in the patent. He says further: "All such differences are immaterial. Matter relating merely to form and location are not the essence of the invention. The specification expressly states that the principle upon which regulating devices operate is well known and that almost any form can be used. It is thought that the defendant's combination operates in substantially the same manner and accomplishes the same result as the combination of the claim."

It is clear that the communication from the Consolidated Company does not fairly state the case when they say that it affects nothing but a particular kind of indicator on a switch and that it has nothing to do with the electric heating system. Anyone at all familiar with electric heaters knows that where one switch is used to vary combinations of heat, it is absolutely necessary to have an indicator to show what the combination is. All who have attempted to make car heaters have gone to considerable expense to get up some kind of an indicator switch for the reason that for a variety of combinations, without this kind of a switch, a number of independent switches were necessary and the street railway companies seriously object to putting up a switchboard in each car. While the Consolidated Company have not yet appealed their cases, they have stated that they intend to. In the meantime favorable action has been taken by the court on an application for an injunction against the Consolidated Company in addition to the judgment against the Albany Railroad.

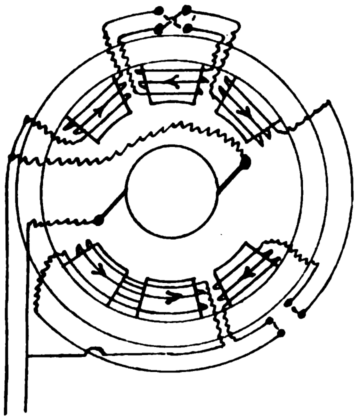
All who use an indicator switch in connection with heaters infringe the Dewey patent No. 464247, which is the subject of this discussion.

AMERICAN ELECTRIC HEATING CORPORATION,
JAS. I. AYER, General Manager.
Boston, Mass.

ANTHONY'S METHOD OF SPEED CONTROL FOR ELECTRIC MOTORS.

I HAVE just received The Electrical Engineer of Feb. 10, containing Prof. Anthony's remarks on my criticism of his method of speed control for electric motors. These remarks show that the description given in the original article was somewhat misleading. In that article (in The Electrical Engineer, of Dec. 16, 1896) reference is made to the machine as a multipolar machine. This is absolutely a misnomer, since Prof. Anthony's scheme, as he now explains it, requires a bipolar machine. Had his first description been sufficiently clear to bring out this point, I should have referred him to a German patent by R. Bauch, No. 83635, issued May 9, 1894. This patent is even older than the one I cited in my previous communication.

This whole subject of motor regulation has been gone over extensively in years past. The multipolar scheme, as I have shown, is the one most frequently used, on account of the fact that a multipolar machine is, in general, cheaper to build than a bipolar machine for the same output. Mr. Bauch's patent is very broad, and diagram b, under Fig. 2, here reproduced, illustrates the idea plainly.



Prof. Anthony states that he has been unable to find the German and French patents which I quoted. I thought that I had made a mistake; but I find that I was right, the German patent being, as before mentioned, No. 84182, issued June 10, 1894, to J. A. Essberger.

With reference to the sparking, I wish to say a word against the antiquated method of accounting for sparking by "disappearance of the lines," and other similar phrases, as employed in Prof. Anthony's original article. This is a very common error, and I hope that I may have the pleasure of dealing with the point further at the next meeting of the American Institute of Electrical Engineers in the topical discussion.

JOHN BALCH BLOOD.
Berlin, Germany, March 8, 1897.

DANGER IN POLE LINES.

A CORRESPONDENT sends us the following notice appearing in the South African Mining Journal, Johannesburg, Transvaal Republic:

THE RAND CENTRAL ELECTRIC WORKS, LIMITED.

"The public are hereby cautioned that the electrical conductor of the Rand Central Electric Works, Limited, running from the company's central station at Brakpan to the Farm Langlaagte is about to carry current, and are therefore warned against touching the electric wires directly or indirectly (such as by means of a stick or whip or otherwise), or in any way damaging the iron poles, or interfering with the line in general. The conductor is easily recognizable, the iron posts being painted red, and showing a Death's head, with the words 'Wire, Dangerous.'

"RAND CENTRAL ELECTRIC WORKS, LTD."

Our correspondent adds that on the high potential lines in Colorado, in damp weather, the linemen run and jump at the poles, being careful not to have contact with the pole and earth at the same time.

MASTERPIECES OF LITERATURE.

THE two volumes just issued of Charles Dudley Warner's Library of the World's Best Literature repeat the excellence of those gone before. The two volumes now before us range from Bion, the Greek poet, to James M. Barrie. Along with a remarkably intelligent and sympathetic study of Mr. Barrie's genius is given the best of his stories, and even a fine episode from "Sentimental Tommy," which in a work of the magnitude and enduring quality of the library, is keeping up to date with an emphasis.

One of the most interesting sections in this volume is that devoted to Balzac. Mr. Warner's library makes it possible to get out of the great bulk of Balzac literature just what the general reader ought to have.

"Masterpieces every one," may truly be said of the varied and interesting contents of the library, also of the the special articles prepared by over three hundred literary celebrities of this country and Europe. In these exhaustive reviews, not only individual authors but entire fields of literature of Assyria, for instance, Egypt, even South America—are covered, giving the reader a connected, comprehensive and impressive idea of the history of the rise and progress of the literatures of the world from the earliest time until to-day.

With the aid of these thirty volumes one may acquire in a season's easy reading a wider grasp of literature than could otherwise be obtained by the industrious study of a lifetime.

The first edition is, of course, the most desirable, because printed from the fresh, new plates. Usually a higher price is charged for this edition, but the publishers of the library have actually reduced the price, and are making a special offer, so as to place a few sets in each community for inspection. The buyer, who acts promptly, saves nearly half the list price, besides having the privilege of easy monthly payments. But it is possible to take advantage of this price through Harper's Weekly Club only, which offers a limited number of sets, to introduce and advertise the work.

The demand for this most desirable first edition is so active and the number of sets allotted to be distributed so limited, it is safest for those who really covet this invaluable library of Mr. Warner's to write at once to Harper's Weekly Club, 91 Fifth avenue, New York, for sample pages and special prices offered to members of the club now forming.

VOL. XXIII. NEW YORK, MARCH 31, 1897. No. 465.

THE INFLUENCE OF HEAT ON MAGNETIZED STEEL.

THE influence of heat on the magnetic properties of iron and steel has been the subject of several classic treatises which have thrown much light on the subject and led to valuable practical results in the treatment of iron and steel, especially in relation to dynamo-electric machinery and transformers. That this field of study is not exhausted, however, is evident from the excellent paper read before the American Institute of Electrical Engineers at its last meeting, by Dr. K. E. Guthe. About twelve years ago, Barus and Strouhal in an exhaustive article embodied in the United States Geological Survey Reports, showed the influence of tempering on the retentivity of steel magnets, and originated the well-known method of seasoning magnets by subjecting them for several hours to a temperature of 100 degs. It was this and some additional results that Dr. Guthe took as a stepping stone to further work in the investigation of the effects of annealing. Without going into the details of the eleborate tests made by Dr. Guthe, we deem it of importance to draw attention to some of the principal results obtained. Thus he found that: 1. The point at which steel becomes magnetically hardened by quenching, lies at different temperatures, according to the amount of carbon contained. It is considerably lower in high carbon steel than in low carbon steel, and corresponds closely to the different temperatures at which occur recalescence of steel. 2. The higher above the point of recalescence steel is heated before being quenched, the harder it is magnetically. 3. The magnetic hardening produced by quenching is the larger, the higher the percentage of carbon. 4. Reheating has in general a softening effect upon the magnetic properties of hardened steel, i. e., the permeability increases, and is accompanied by an increase of maximum induction and a decrease of the coercive force. But a hardening is noticeable in the low carbon steel after it has been reheated for a short time to 100 degs. The greatest change in the maximum induction takes place for high carbon steel between 200 degs. and 300 degs., for low carbon steel between 300 degs. and 450 degs., beyond which temperature there is hardly any change in the practical limit of saturation. All change taking place in reheating beyond 450 degs. consists in an increase of permeability for small magnetizing forces, i. e., a decrease in the coercive force or hysteresis loss. 5. To produce strong magnets, the hardened steel should first be heated to 450 degs. 6. Heating to a high temperature below the point of recalescence and sudden quenching produces a steel with a very weak retentivity; in consequence of which the hysteresis loss in a cycle is greatly decreased. This result may also be obtained, though in a lesser degree, by annealing at a very high temperature.

The results above indicated are directly applicable to a variety if important electrical apparatus, not the least important being its bearing on the manipulation of magnets for electric measuring instruments. For, in spite of the old objection to the employment of permanent steel magnets, the fact remains that instruments embodying them in their construction are to-day the most accurate and reliable for commercial measurements, while even in the laboratory they are coming into more general use on account of their great convenience. Their permanency of indication must always rest on the efficacy of the hardening and ageing processes employed for the magnets, and anything that can add to our present knowledge on the subject, such as the work of Dr. Guthe, is of direct benefit to the whole profession.

CHEAP RAPID TRANSIT.

THE recent struggle of the Metropolitan Traction Company in this city to secure further privileges has been sucessful so far, and may be expected to give the city an early increase in its facilities for rapid transit. The new electric lines will run practically the entire length of the Island of Manhattan, from one tip to the other, and thus by paralleling the surface and elevated lines in existence will not only add new conveniences but stimulate the old. Although in a sense parallels, the new lines open up new territory and will create a large travel of their own, while the welcome awaiting them was oddly proved by the attitude of the dwellers on Eighth avenue, who fought tooth and nail against the proposition of the company to turn aside at Fifty-ninth street, an uptown artery, into Sixth avenue, and leave lower Eighth without the modern service. But a few short years ago, the fight would have been altogether the other way, and the newspapers would have been filled with denunciations and lurid pictures of the dangers of electricity. Travel is pretty cheap in New York to-day, but it will now be better and cheaper than ever. What has been also accomplished in Chicago, is shown by a diagram appearing on another page, which shows that the average distance which can be traveled there for 5 cents has rapidly increased from 4 to 15 miles. This is the more remarkable when we consider the density of population, upon which the earning capacity of a street railway system must so largely depend. Mr. P. F. Sullivan, the manager of the Lowell and Suburban Railway, has issued recently for private circulation, the notes made by him during a tour of observation in Europe, and he brings out some significant facts. He shows, for example, that Chicago has only 2,857 population per mile of track, and New York 4,042, St. Louis having but 1,922 and Cleveland 1,371; while Liverpool has 10,000 per mile, Manchester, 10,400; Glasgow, 11,507; Berlin, 10,000, and Paris 13,587. If anybody said that our roads in cities have too many miles of track, on this basis of comparison, it would be defensible. But the public would not agree with that proposition, and hence it would follow that the European cities are very much under-equipped.

Mr. Sullivan, we are glad to say, administers the final coup de grace to the fantastic legend that out of the operation of its municipal street railway system Glasgow is in process of paying all its running expenses and liquidating its entire indebtedness. The story is still going the rounds, but its usefulness as a choice piece of misrepresentation is now obviously limited. It appears that the city of Glasgow has an average of 10,000 employés and disburses $10,000,000 a year in such expenses, or six times the total gross receipts from the street railways! The net returns to the municipal treasury from the roads, moreover, is only $45,000 a year, nominal. The city debt just now is $39,852,175. We leave our readers to figure out how soon the $45,000 will overtake the $39,000,000 besides providing salaries meantime every year for the army of 10,000 city officials.

As to the service given, Mr. Sullivan states that in November he paid six cents for a ride in Glasgow and in December 10 cents for a ride in Berlin, and that in any city in Massachusetts he could get a longer ride, in better cars, for the regular fare of 5 cents. Of course one could ride a shorter distance for a smaller fare in the European cities, especially on the roof, exposed to all weathers, but Mr. Sullivan calls attention to the fact that the higher fare for the longer distance is the very reason why there is such terrific overcrowding in cities like Glasgow, Paris and Berlin, and why in the United States, the cheap rates for the long distances are building up large suburbs full of beautiful little homes, enjoyed by people who would otherwise be cooped up in garrets or cellars. Mr. Sullivan says, in addition to this, that not only are fares actually higher in Europe than here, requiring more equivalent in hours of labor at current rates of wage; but that under the further conditions of density of population, low mileage and careful protection afforded to capital in such enterprises, railway investments are more desirable and are better in Europe than in the United States. This may be the reason why some of our most enterprising street railway men have been securing the ownership of some of the larger properties in Europe, to develop them on the best lines of American practice.

THE TELEPHONE IN NEW ENGLAND.

A PROPOSITION having recently been made in Massachusetts to establish a telephone commission, Mr. S. L. Powers appeared before the committee on mercantile affairs of the Massachusetts legislature to oppose it in behalf of the New England Telephone and Telegraph Company. We must confess our own belief in the general efficacy of such commissions, on the Massachusetts plan; but in view of the fact that only eight subscribers in eight years have asked for one, and that 16 subscribers have objected, it would seem that there is no great need or yearning for it just now in that State. What is of more interest is the remarkable data brought forward by Mr. Powers as to the use of the telephone in this country.

The population of Europe in 1890 was 354,957,776, and there are 336,037 telephone stations, or 1 to every 970 of the inhabitants. The population of the United States was 62,622,250 in 1890, and there are 325,810 telephone stations, or 1 to every 192 of the population. Moreover, while in Europe the telephone conversations reach 767,109,824 per year, here they reach 757,000,000. Hence it follows that measured by population the number of telephones in this country is five times as great as in Europe and the use per capita is six times as great.

If we descend from the general to the particular, we find that while Sweden, the most liberal user of the telephone in Europe, has but 1 to every 136 of her inhabitants, the Commonwealth of Massachusetts has 1 to every 95. The little Bay State has very nearly as many telephones as the great republic of France, which has fifteen times her population. If we come to cities, London has 1 instrument to each 700 of her population, while Boston has 1 to every 55; so that London, with 8,000 exchange instruments, plays second fiddle to Boston, with over 9,000. These, surely, are striking proofs of the general use of the telephone in this country, and when we come to rates and service, the advantage is still found to remain on our side. Mr. Powers quotes a great many statistics on this point, going into the relative quantity of service obtainable, the average prices of labor, and the general use made of the system; but while this is convincing the best proof one can have is to go to Europe and try it for one's self, in any country that may be selected. To-day in New England each use costs the subscriber only 2½ cents, a price hard to beat.

We might dwell on these figures but there seems to us even more interest in the analysis that is furnished of the earnings of the New England Company. A great many of the "independent" local telephone companies have made their remarkable headway by asking low rates, and we are afraid that the public is being educated in many places to a much lower tariff than the business at any time can stand. Competition is an excellent thing, on the right lines, but we cannot see what the business or the art of telephony is going to gain if it is to be done at a loss. The real question narrows down to an inquiry into what it does cost to carry on a good exchange system, and in this connection some figures we collate from Mr. Powers' argument may be valuable. He gives the following as authentic: The company receives on an average from its exchange and pay station instruments $74.56 per year. Out of this comes, labor, $36.26; taxes, $6; American Bell rental, on the average, $5; rent, insurance, material, office expenses, etc., $9.75. This makes a total of $57.01 for operation and maintenance. We do not note any allowance for depreciation, which would obviously make a further considerable deduction from the amount available for dividend. The New England Company appears to be paying at present $5.00 annual dividends per share of $100, but the average over 15 years is only $2.70. The issued capital of the company is $10,390,000, and as in Massachusetts the company pays on a taxable valuation of over $8,000,000, it is reasonable to assume that the property in Maine, Vermont and New Hampshire is worth at least the remaining $2,390,000; so that there is no "water" discoverable. It is curious that the company pays less as a Bell royalty than it does as taxes, on each instrument; and there may be something in the contention of Mr. Powers that for an equal amount of $5, the New England Company could not afford to maintain a shop to make and repair its own apparatus, as it would do if not dealing with its parent company.

There are several interesting points here suggested, many of which it is difficult to pronounce even an opinion upon, but a full understanding of which would go far to reveal the future of telephone exchange work in this country, as a profitable enterprise.

THE GRIEVOUS TALE OF GRAVESEND.

We doubt whether the annals of unsuccessful municipal lighting plants present a more pitiable and pathetic record than that of Gravesend, Long Island. This plant cost the town $119,000, to raise which a lot of common lands were sold. The real value of the plant at the time of its installation was less than $60,000, and where the rest of the money went does not appear. The plant has just been sold to the Brooklyn Edison Company for $31,000, which will be eaten away by other charges and is all the town has to show for lands which, it is generally understood, were disposed of in another little deal, far below their intrinsic or prospective market value. The plan was put through by Mr. John Y. McKane, then the political boss of Gravesend, who was sent to Sing Sing for several years for wholesale fraud in elections. There is no doubt that had his career of usefulness not been cut short, Mr. McKane would have operated the plant, and the neat little problem now presenting itself to the citizens is to figure out whether they would have been actually better off, if the plant had been used. A nominal saving of so much per lamp, as compared with rates from a private company, might, they think, have meant a big addition to the municipal indebtedness, and they have at least escaped that. As it is, the plant was never in regular working order, and it is said that never a single lamp was lighted from the city dynamos. Next!

INTENTIONAL DISABLING OF MACHINERY.

Down on Long Island, at the pleasant summer resort of Southampton, a man has been held for trial on the charge of sanding the dynamos and machinery of the local electric light company. The facts in such a case would seem easy to establish, as one does not apply sand to dynamos with a box, as a lubricant; and if the deleterious substance is there, the presumption is that some one put it there, either the person accused or another. We are glad to believe that the malicious disabling of machinery is much less in vogue than it once was. The reports of such accusations even as this are rare, and in cases of embittered industrial strife, the great majority of the men show themselves anxious to abstain from destructive acts that wipe out so much of the wealth of the community. Their intelligence teaches them the deep truth of Prof. Hadley's recent remarks that "Investments of capital in machinery, on however large a scale, have tended to create an increased demand for the services of the laborer as a producer, and a yet more conspicuously increased competition for his purchases as a consumer." In other words, the disabling of machinery by accident is a recognized misfortune for all; and, by intent, is a crime against labor more even than against society as a whole.

THE STOCK TICKER SITUATION.

The position that we took last week as to the duty of the Western Union Company in regard to the "bucket shops," is now sustained, as will be seen from our Legal Notes, by a Western decision, namely, that it is broadly the function and province of the company to treat all comers alike; and, correlatively, that of the legal authorities to suppress institutions making a bad use of the service or of the information. When we see the whole legal machinery of the government exerted, in another direction, on the telegraph company and the steam railroads, to establish equality for all customers, it is too much to expect the exactly contrary proposition also to be supported. In this matter, the Western Union Company represents the widest interests of the public. If the courts and officers of justice cannot take care of evil-doers, it is as well to know it, and to mend the law. But it is pushing things beyond the limits of propriety, into the region of absurdity, to expect a telegraph company to investigate the moral character of people anxious to get its service and tendering good money for it.

Stealing current is now to be a definite offense in Connecticut. There have been a good many instances of the "sneaking away" of little quantities of current, but when detected, which has not proven difficult or long in occurring, the trouble has been to get a verdict, either because the thief said he had permission or it was hard to show exactly how much he had stolen, or the court would not regard electricity as a tangible, material thing. The little wires for these paltry thefts have usually been taps inside a room or a hall, lighting one or two lamps, and contrast very forcibly with the other cool plan of putting in circuits and installations that will allow a burglar undetected to steal and work with currents that would easily run anywhere from 250 to 500 lights! To get the best safe he can, must ever be the first duty of a banker, but we confess we don't share any anxiety as to the use of the current en bloc for burglarizing such safes by the electric arc. The idea is not one for commercial consumption, but ought certainly to be brought to Jules Verne's attention as affording a good plot for his next novel.

They must be pretty good arc lights at Utica, N. Y. One of the aldermen stated in the common council last week that he had moved a lamp to which reference had been made, because two people had complained that it was so intense they could not sleep; and the complainants had even gone so far as to ask for smoked glasses to be put around the lamp if it was not moved. We should say that those lamps are undoubtedly full 2,000 candle-power.

ELECTRIC TRANSPORTATION

THE DIAGONAL SYSTEM OF RAILWAY LINE CONSTRUCTION.

BY JOHN C. HENRY.

RECENTLY I have been making an estimate on the cost of constructing a long electric railroad in the mountains. In scheming to cut down the expense, it occurred to me that a very considerable saving could be made by using a slight modification of the writer's previously described diagonal methods of support. The plan shown in the above sketch requires but one-quarter of the number of poles that the ordinary span construction does, or but one-half the number required by the bracket construction. In addition, the span wires may serve as feeders and also act as stays for such pull-offs as may be required on long curves. The span has other advantages; among them, the liability of the poles being broken down by land slides, falling rocks, runaway teams, etc., is reduced in proportion to their number.

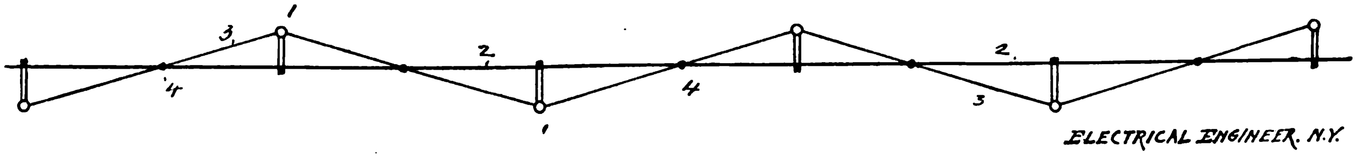

FIG. 1.—HENRY'S METHOD OF DIAGONAL SUSPENSION OF TROLLEY WIRES.

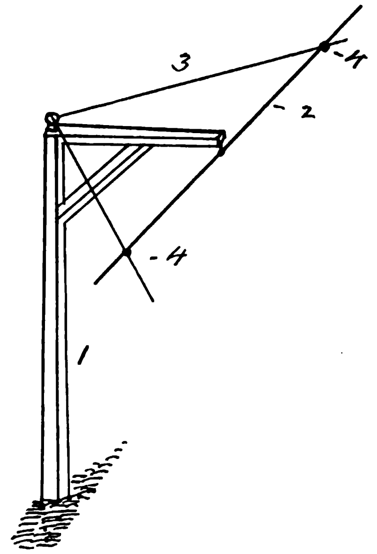

FIG. 2.

In the sketch, Fig. 1, 1 represents the ordinary bracket poles, and Fig. 2 a plan view of the line construction. Trolley wire is shown at 2; the diagonal span wire and feeder at 3, and the insulating hanger at 4.

MR. T. DOLAN ON THE SUB TROLLEY AND AIR MOTORS.

MR. THOMAS DOLAN, of Philadelphia, who is one of the men most largely interested in the Metropolitan Traction Company, of New York City, was interviewed last week as to the preference shown for the sub-trolley and the decision not to adopt the compressed air motor. As to the failure of the air motors, he said: "We have reason to know, for we have spent a year's time and much money endeavoring and hoping—at one time almost believing—that we had found in it just what we wanted. We are working on it to-day in our experiment shops, and we are far enough along with it to know and to understand the obstacles that are yet in the way of its successful operation. Compressed air may be made practical as a motive power in a month, or six months, or six years—perhaps never. Nobody can tell. Its perfected form is still in the inventor's brain. One car does not constitute a system any more than one swallow makes a summer. There is a difference between operating one car and operating several hundred cars. You can have skilled experts handling the one car, doctoring it between trips, and all that sort of thing. It is a much different matter when you attempt to operate an entire system. You cannot have experts on every car, skilled in the technicalities, nor can you lay the cars up for repairs. They must be moving all the time. Why, there is every reason why we should be acting in this matter only after the most painstaking investigations. It is to our interest to have the best possible motive power. We cannot invest millions to-day to be dug up and thrown away to-morrow. It is our business to get the best."

With regard to the conduit system, he said: "Two years ago we heard of the underground conduit in Budapesth. We sent our engineers over there to study it, and they reported it imperfect. Finally, the General Electric Company offered to build an underground conduit on Lenox avenue, in New York City, and to remove it if it proved a failure. We accepted the offer, and the line has been in successful operation nearly two years. A year ago, at this time, we had determined to change our motive power to the underground, and were about to do it when the compressed air system was brought to our attention. Instantly we abandoned our purpose to lay conduits and began costly experiments with compressed air. It looked at one time last summer as though the air motor would answer, but fuller tests proved that not to be the fact. Meanwhile the conduit system has been perfected. The question before us is: 'Shall we give the people of New York City rapid transit now or, in order to save money, wait an indefinite period until some system now undeveloped can be perfected?' We answer that inquiry by offering to go right ahead with the underground."

ELECTRICITY ON THE CHICAGO ALLEY ELEVATED.

Steam power is to be superseded by electricity as motive power of the Chicago Alley "L." The road will also be connected with the Union loop and will carry passengers into the downtown districts instead of leaving them at Congress street. It is designed to make the trains run almost as fast as those of the Illinois Central. Management of the Alley "L" will extend its lines into the present territory of the railroad company and make a fight for a larger share of the South Side patronage. Engineers are at work on specifications for bids on equipping the road with electricity. The plant will be ready in six months, if present plans are carried out. Work will be commenced on the connecting track with the Union loop as soon as Mayor Swift signs the ordinance passed recently. Fifty motors will be built for the road by Sargent & Lundy at a cost of between $400,000 and $500,000. The coaches now in use are to be reconstructed. Other changes and the electric plant will cost $1,000,000. A third rail will be used. To make it a more formidable rival of the Illinois Central, President Leslie Carter and other officers and directors of the Alley "L" will make the passenger cars comfortable to a point of luxuriousness, and will cause trains to be run almost as frequently as street cars.

ELECTRICITY ON THE "L".

Mr. George J. Gould has denied that the officials of the elevated railroad had abandoned the idea of equipping the road with electrical motive power.

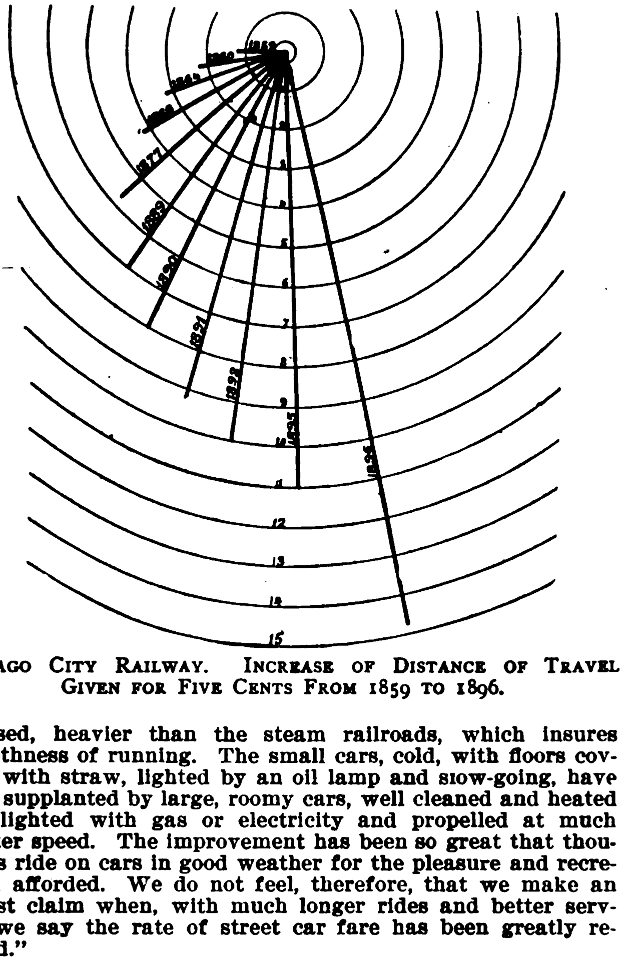
"I am studying the subject all the time," said he, "and am as much an enthusiast about electric motive power as ever."

TROLLEY vs. STEAM AT PITTSBURG.

Recent experiments on the Monongahela have once again shown, says the Pittsburg Post, that the steam roads cannot compete with the electric lines for the suburban traffic. The best they can do is to hold their own legitimate share of the business. Since the building of the electric roads much traffic has been developed at points far removed from the railway stations, and this cannot be attracted by frequent train service on the steam roads or lower rates.

HOW FAR ONE MAY TRAVEL FOR FIVE CENTS IN CHICAGO.

ONE of the best appeals for fair treatment, addressed to the public of a great city, is that put forth by Mr. G. H. Wheeler, president of the Chicago City Railway Company, through the pages of the local newspapers. The pith of the argument is found in one of the diagrams, which we reproduce here. It shows the growth in the distance that a passenger can travel in 1896 for one 5-cent fare, as compared with the distance in 1859. The exhibit is certainly a very striking one, although it could probably be duplicated in other cities. But as Mr. Wheeler says, it does not tell the whole story. "Notwithstanding the cheapening of the cost of a ride the improvement in the physical condition of the railways has been marvelous. Instead of a light, rough-running track, a girder rail is used, heavier than the steam railroads, which insures smoothness of running. The small cars, cold, with floors covered with straw, lighted by an oil lamp and slow-going, have been supplanted by large, roomy cars, well cleaned and heated and lighted with gas or electricity and propelled at much greater speed. The improvement has been so great that thousands ride on cars in good weather for the pleasure and recreation afforded. We do not feel, therefore, that we make an unjust claim when, with much longer rides and better service, we say the rate of street car fare has been greatly reduced."



Chicago City Railway. Increase of Distance of Travel Given for Five Cents From 1859 to 1896.

The Chicago City Railway Company has to-day 184 miles of track, 25 miles of which is in territory that is far from being able to support the service afforded. The company employs from 3,500 to 5,000 men.

THE NORTHERN OF NEW JERSEY MAY ADOPT ELECTRIC MOTORS.

The Northern Railroad of New Jersey, it is reported, is contemplating changing its motive power and adopting electrical propulsion. It is also said that if the road decides to adopt this method of operation it will have its terminus at the Hoboken Ferry and will build branches in different directions so as to compete with the Erie, the New Jersey and New York and the Susquehanna for local and through traffic at points not now touched by the Northern.

BIG NEW RAILWAY PLANT FOR PITTSBURG.

The Consolidated Traction Company of Pittsburg intends, apparently very soon, to begin the erection of an immense power plant, the building and machinery to cost about $400,000. The plant is to be located, so it is stated, at Twenty-sixth street, near the Allegheny River, which would be not far from Penn avenue. The contracts for supplying the machinery will be awarded at once. The machinery will cost between $250,000 and $300,000, and will consist of engines, boilers, dynamos, etc.

The building will cost in all probability about $125,000 and will be a large structure. It looks as if the work of building would be commenced the coming summer.

ELECTRIC TRACTION FOR LIMA, PERU.

J. Mitchell de las Carreras of Lima, who has been in this city some time for the purpose of transferrring the Lima Tramway Company to an American company, entitled the South America Light, Power and Traction Company, has effected his plans and will soon return to Peru. The above company is now controlled by Messrs. Hearst & Stump, of New York City; ex-Senator Paddock, of Nebraska, and Mr. A. Murphy, of Omaha. The new company proposes to change all the horse car lines in the city of Lima to electric roads. Negotiations are already being effected with different electric companies for estimates, etc. Mr. Carreras says that some very advantageous concessions which the government of Lima made with the old Tramway Company have been transferred to the new company, among them the privilege of importing all the materials for the roads free of duty. The government, this gentleman also says, is inclined to give the new company the concession for the electric light plant to be built in the city of Lima.

ELECTRIC MINING FREIGHT ROAD FOR CALIFORNIA.

An electric railway to operate in Summit and Park counties, California, is about to be incorporated for the purpose of furnishing transportation facilities to mining camps which have been shut out of the market owing to the high price attendant on existing means of hauling. The line will start at Alma and Breckinridge, where connection may be had with the South Park railway leading to the Denver smelters. It is estimated that the electric line can handle 200 tons a day at a cost of not to exceed one dollar a ton, owing to the power being generated on the right of way by mountain torrents whose waters have been going to waste. M. M. Howe, an experienced mine manager, is at the head of the project and with him are associated J. P. Pierce, of Buffalo, N. Y.; Judge Hibbard, Paul Marker and W. F. Fox, of Chicago; J. W. Boone, of Syracuse, N. Y.; Henry Clews and Melville E. Stone. The road will cost about $100,000, and will be in operation by the middle of September.

ELECTRIC RAILWAY WORK AROUND NIAGARA.

The Tonawanda Electric Railroad Company, of Tonawanda, N. Y., and the Tonawanda Street Railroad Company, of North Tonawanda, N. Y., have been granted the privilege of crossing the bridge across Tonawanda Creek. Workmen are now engaged in strengthening the bridge for the extra load brought on by the street railroad traffic, and will have it completed in about one week, giving through service from Gratwick and North Tonawanda to the Buffalo city line. It is contemplated that the line of these two roads will be consolidated and extended to Niagara Falls, forming a through line from Buffalo to Niagara Falls and will be operated under the name of the Buffalo, Tonawanda & Niagara Falls Electric Railroad Company. Much of the right of way has already been secured and the preliminary work is being pushed forward as rapidly as possible. The lack of permission to cross the bridge above referred to has been a great detriment to the roads in the past. This bridge will be the means of giving better service to the public and a better revenue to the company.

MOVING HOUSEHOLD GOODS BY TROLLEY.

A novel electric train went north on High street about 10 A. M. over the lines of the Columbus Street Railway. It consisted of the sand car and one of the construction cars, both loaded with household goods, stoves, beds, carpets and all manner of requisites for housekeeping. Inquiry developed that the goods belonged to Mr. Wolfe, one of the faithful employés of the company, who has been living on Oak street, near the Rose avenue sheds, but has been given the occupancy of the house at Olentangy park, owned by the company. The train of two cars furnished an admirable means of making the transfer.—Columbus (O.) Dispatch.

POWER TRANSMISSION

ELECTRIC HOISTS IN MINING WORKS.

THE application of the electric motor to hoisting work and the appreciation of the combination by mine operators is shown by the numerous installations of electrical hoists which have been made in mines during the past few years. In the operation of these hoists, it has been found that they markedly emphasize the advantages of electrical operation. They may be located in relation to the incline of shaft exactly where they can be operated with the greatest advantage consistent with convenience of position, without any of the pipes inseparable from the air or the steam hoist. In responsiveness to the movement of the starting lever, the electric motor is instantaneous. There is no short interval of hesitation as in the steam hoist. The speed is constant and only the requisite power required to handle the load is consumed, while the general cost of operation is less than with compressed air or steam hoists.

These points in favor of the operation of hoists by electricity have been demonstrated in many instances, and the following may be looked upon as affording additional evidence. At the Free Silver Mine at Aspen, Colo., is an electrical hoist, Fig. 1, rated at 125 horse power, but capable of applying to the hoisting machinery power to the extent of 200 horse power. This is the largest electrical hoist in the world. It is a double reel, flat rope, overbalanced hoist built after the designs of Mr. D. W. Brunton, manager of the Free Silver Mining Company, and also of the Cowenhoven tunnel, Della S., Alta Argent and Johnson Mines. The electrical equipment consists of one General Electric Company's 100-kilowatt multipolar motor, with a speed of 550 revolutions per minute, and a smaller motor of similar type of 60-kilowatt capacity, and a speed of 475 revolutions. This smaller motor is ordinarily used to run an air compressor and winch for pulling pumps, but in case the main hoist motor is called upon for heavier work than usual, the smaller one can be thrown in gear with it.

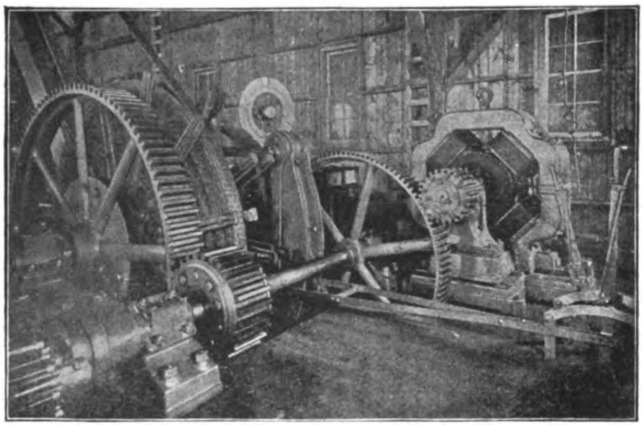


FIG. 1.—OVERBALANCED HOIST, FREE SILVER MINE, ASPEN, COLO.

The hoist being counterbalanced, the load on the motors is reduced to about one-third of that which would be thrown on a plain hoist of the same capacity. The radius of the arms of the reels is 5 feet, each reel carrying 1,500 feet of rope 4 inches wide and ⅝ inch thick. The hoist is provided with a car and cage, and the loaded car and cage weigh about 5,000 pounds. As in sinking the mine it cannot be timbered entirely to the bottom, and the cage cannot go below the timbering, a bucket is hung below the cage. This is 35 inches high and about 28 inches in diameter. It weighs 400 pounds, and holds 12¾ cubic feet of water, weighing 800 pounds, or rock weighing 2,000 pounds. To relieve the shaft from a sudden inflow of water, this hoist is provided with a bailer, which is used as an adjunct to the pumps. This is 4 feet 2 inches by 3 feet 2 inches by 8 feet 4 inches and weighs empty 1,950 pounds, and filled 8,880 pounds. The counterweight used with the cage and bucket is 2,450 pounds with the cage and car 2,675 pounds. With the bailer these two weights are used, making a total counterweight of 5,125 pounds. The maximum hoisting speed with the cage and ore, and using the small pinion on the motor, is about 600 feet per minute; with the bailer and using the larger pinion about 1,000 feet per minute. The voltage used is 525 volts, and the current is taken from the central station at Aspen.

Last summer an interesting test was made with this hoist when using it for bailing. At that time the mine shaft was 835 feet deep, a depth to be ultimately increased to from 1,200 to 1,500 feet. The condensed figures showing the operation of this hoist during the test are as follows: Hoisting: Weight of bailer 1,950 pounds, water 6,930 pounds, total, 8,880 pounds; counterweight, 5,125 pounds; (ropes balance, considering entire trip); net weight raised, 3,755 pounds; depth of shaft, 835 feet; work, 3,755 x 835, 3,135,425 feet pounds; time hoisting, 2:25 min.; foot-pounds per minute 1,393,521; mechanical horse power, 1,393,521 ÷ 33,000 = 42.2.

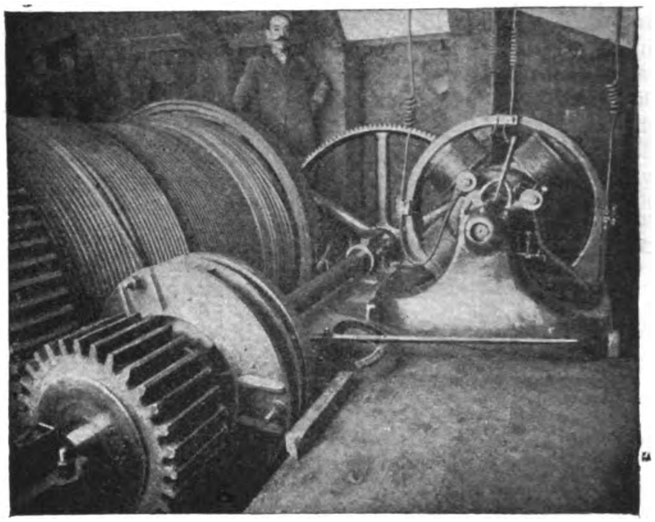

FIG. 2.—ELECTRIC HOIST, ALTA ARGENT MINE, ASPEN, COLO.

Lowering: Counterweight, 3,175 pounds; weight of bailer empty, 1,950 pounds; (ropes balance, considering entire trip); net weight, 3,175 pounds; depth of shaft, 835 feet; work, 3,175 x 835, 2,651,125 feet pounds; time of lowering, 2:25 min.; foot-pounds per minute, 1,178,277; mechanical horse power, 1,178,277 ÷ 33,000 = 35.7 horse power.

At the Alta Argent Mine, also at Aspen is another hoist, Fig. 2. This is placed at the head of the incline. The current is taken from the power plant of the Roaring Fork Electric Light and Power Company, three and one-half miles distant, two miles being above the ground and one and one-half miles through the Cowenhoven tunnel and mine workings. This hoist is also overbalanced and is equipped with a General Electric Company's multipolar slow-speed 500 volt motor, having a capacity of 20 horse power.

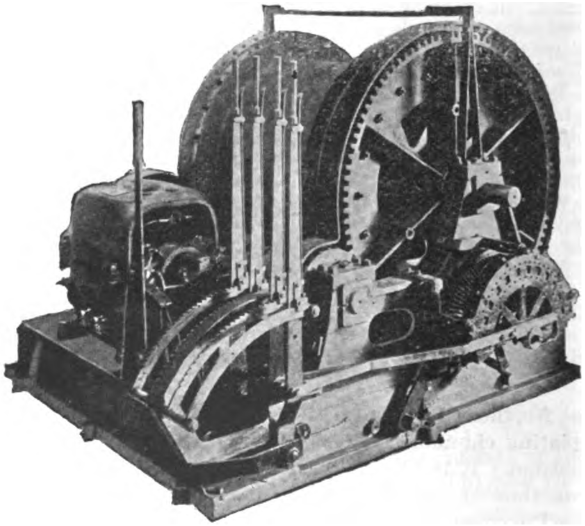

FIG. 3.—ELECTRIC HOIST, PLEASANT VALLEY COAL MINE, CASTLE GATE, UTAH.

The location of this hoist has been arranged with an eye almost exclusively directed to the convenience of handling the cars. The hoist is placed on a platform about 10 feet above the level at the head of the incline, where the ore cars are stopped and run off after being hoisted. Here the hoist operator stands and handles his controlling levers and reversing switch. This arrangement gets the hoist out of the way, while it allows the operator to attend to the cars. In the case of other hoists at Aspen, the hoist is placed directly at the head of the incline. This relegates the operator to the back of the hoist, where he can see both shaft and rope when hoisting and lowering. To attend to the cars he would be compelled to pass around the hoist, and as this entails loss of time, a second man to handle the cars is usually necessary. At the Alta Argent, one man suffices to operate the hoist and handle the cars.

In the mines of the Pleasant Valley Coal Company of Castle Gate, Utah, is another direct current mine hoist used for hauling the coal cars up the incline, Fig. 3. This hoist is a Lidgerwood double-reduction single-drum hoist, equipped with a standard L. W. P. 20-horse-power railway motor and double 51 rheostat. It is designed to lift 4,000 pounds 500 feet per minute. The drum is 47 inches in diameter and 36 inches face with two brake hands in V-shaped grooves on the drums. It is provided with both friction and positive clutches, and is operated by five levers—one for the rheostat, one for the friction clutches, one for the positive clutch and two for the brake. The dimensions of the base on which are mounted the drum, motor and controller, are only 78 inches by 95 inches. Another hoist of similar pattern but using a friction clutch only and a G. E. 2,000 motor with a double 83 rheostat has recently been added to the very complete mining equipment of the Pleasant Valley Coal Company. The motor in this case is fully enclosed.

All of these hoists are and have been in constant service for months without serious hitch or stoppage beyond those necessitated in ordinary mine service. They have been found superior to steam hoisting engines, both in efficiency, in simplicity, in convenience, and in speed of operation, and no better proof can be adduced than that in the three first mentioned cases, the first hoists have induced orders for additional ones.

SCOTT AND JANNEY ALTERNATING MOTOR FOR DESK AND CEILING FAN OUTFITS.

FOR some time past the Scott & Janney Electric and Manufacturing Company, of Philadelphia, have been at work upon a new alternating current motor and are now prepared to place their machines on the market. This type of motor is claimed to be entirely new. No pains or expense have been spared to make this machine of the highest type, both electrically and mechanically. It has been experimented with in all conceivable shapes and sizes in order to make it economical and durable.

The moving part of the motor, namely, the armature and shaft, is simplicity itself. The windings are of cast copper into which the stampings of sheet iron are inserted. The copper casting has no soldered joints and as a consequence the armature can be raised to a red heat without danger to it in any way. There is no insulation in or upon the armature, and hence nothing to burn, shrink or expand except the metal; even expansion and contraction cannot do any damage to this part of the machine owing to its peculiar construction. Strange as it may seem, expansion and contraction will only bind the armature parts tighter together, as there are no screws or bolts used in its construction, it being held together by pressure.

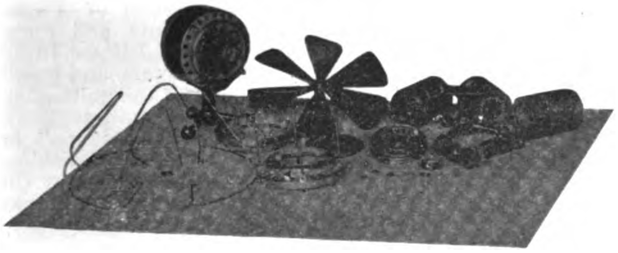

FIG. 1.—SCOTT & JANNEY ALTERNATING DESK FAN.

The armature is of the induced type and, as said before, it is the part which revolves. No commutators, slip rings, or sliding contacts of any kind are used. It is purely an induction motor.

The Scott & Janney motor is claimed to be in a class by itself, even its principle of operation, although caused by magnetism, being different from that of motors heretofore designed.

The main feature of the motor lies in the construction of the magnetic circuits and the windings upon them. These windings are so placed as to cause two field magnetisms or two fluxes to circulate; this is also true of other induction motors, but the difference is that, in other induction motors, the two fluxes occur in the same plane and parallel, but at different times. In the Scott & Janney motor they occur in different planes and at right angles to each other and at different times.

There is another important feature about this motor and that is the proximity of the induced circuits and the currents flowing therein to the primary windings and the magnetic poles. This is an essential feature in motors built for high frequency circuits, but does not prove of so much value in low frequency apparatus, as the projection of the lines of force across an air gap is favored more in low than in high frequency machines.

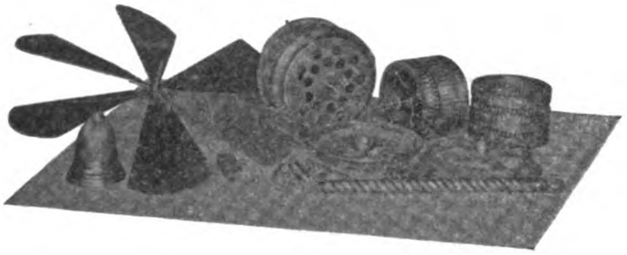

FIG. 2.—SCOTT & JANNEY ALTERNATING CEILING FAN.

The accompanying engraving, Fig. 1, shows the details of construction of the large size desk fan, and Fig. 2 those of the ceiling fan motor. The advertisement of the Scott & Janney Electric Manufacturing Company, elsewhere in this issue, contains illustrations of the completed fan outfits just mentioned.

AN ELECTRIC POWER FACTORY SCHEME FOR HAVERHILL, MASS.

A. J. Tilton, of Haverhill, Mass., is perfecting a big building and manufacturing project which will necessitate the use of $300,000. The proposed plan is to build on the ground owned by Mr. Tilton, and lying between Essex street, Locke street, Little River and the B. & M. tracks, three mammoth factories, each 300 feet long and of mill construction.

In the center there would be built a complete electric power and lighting plant, water to be furnished from Little River, which will probably be arched.

OBITUARY

JOHN M. ORFORD.

We note with deep regret the death of Mr. John M. Orford, assistant manager of the Boston Electric Light Company, who died at his home in Jamaica Plain, on March 23. He gained his electrical experience in the service of the British government, and many years ago was engaged in electrical work in India. Later he left England and had a prosperous career as an electrical engineer, coming to this country. He was for some time general manager of the Bridgeport (Conn.) Electric Light Company. He leaves a widow and four children. He was widely known and greatly liked in electrical circles. The cause of death was typhoid pneumonia.

ADOLPH VOGEL.

Mr. Adolph Vogel, treasurer of the Cambridge Gas and Electric Company, died at his home, 16 Martin street, Cambridge, Mass., on March 24. He was a native of Bohemia and seventy years of age. For a quarter of a century he was cashier of the University Press, and for the past fifteen years he had been treasurer of the Electric Light Company.

SOCIETY & CLUB NOTES

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the Institute held at 12 West Thirty-first street, March 24, a paper was presented by Dr. Karl E. Guthe on "The Influence of Heat Treatment Upon the Magnetic Properties of Hardened Steel." In the absence of the author the paper was read by Prof. H. S. Carhart of the University of Michigan, who took part in the discussion, together with Dr. Pupin and Mr. Winand.

At the council meeting in the afternoon the following associate members were elected: Ernest J. Bechtel, superintendent power plant, Toledo Traction Co., Toledo, O.; Arthur Hillyer Ford, fellow in electrical engineering, University of Wisconsin, Madison, Wis.; Herman L. Holbrow, with New York Telephone Co., New York City, residence Rutherford, N. J.; William F. Kelly, student in expert course, Fort Wayne Electric Corporation, Fort Wayne, Ind.

It was also decided on the invitation of Miss Mary Farmer, to hold the general meeting of the Institute at Greenacre-on-the-Piscataqua, Eliot, Me., beginning Monday, July 26. This date is the 50th anniversary of the entrance of the late Prof. Moses Gerrish Farmer, into the field of electricity, which became his life work. Prof. Farmer was one of the charter members of the Institute and in consideration of his high standing as an original investigator and inventor he was elected an honorary member of the Institute Oct. 21, 1890. His home during the latter part of his distinguished career was at Eliot, Me., and he died at Chicago, May 25, 1893, where he had been engaged in the preparation of his personal exhibit at the World's Fair. Greenacre is already noted for its various conferences and meetings held annually.

The council nominees for the Institute election on May 18 are as follows: For president, Dr. Francis B. Crocker, New York City; for vice-presidents, Dr. A. E. Kennelly, Philadelphia, Pa.; Chas. S. Bradley, New York City; Prof. Dugald C. Jackson, Madison, Wis.; for managers, Dr. Alexander Macfarlane, South Bethlehem, Pa.; Gano S. Dunn, New York City; W. F. C. Hasson, San Francisco, Cal.; Herbert Laws Webb, New York City; for treasurer, George A. Hamilton, New York City; for secretary, Ralph W. Pope, New York City. The officers whose terms have not expired are Vice-Presidents Chas. P. Steinmetz, of Schenectady, N. Y.; Prof. Harris J. Ryan, of Ithaca, N. Y.; Prof. Wilbur M. Stine, Chicago, Ill. Managers, Chas. F. Scott, Pittsburg, Bion J. Arnold, Chicago; Carl Hering, Philadelphia; Dr. Cary T. Hutchinson, John W. Lieb, Jr., and F. A. Pickernell, New York City; Prof. Wm. L. Puffer, Boston, and L. B. Stillwell, Niagara Falls.

THE MISSOURI WATER, GAS AND ELECTRIC LIGHT ASSOCIATION.

A special dispatch from Sedalia, Mo., of March 16, says: The Missouri Water, Gas and Electric Light Association held its third annual convention here to-day, J. A. Montgomery, of Sedalia, presiding, with C. F. Strohm, of Nevada, as secretary. A resolution was adopted favoring uniform rules all over the State for wiring and plumbing, under the supervision of inspectors to be appointed by the cities.

J. B. Quigly, James A. Montmogery, of Sedalia; S. J. H. White, of Carrollton; Wort, of Independence, and C. F. Strohm, of Nevada, were appointed a committee on rules and regulations for the government of wire fitters, plumbers and architects, the rules to conform to the rules and regulations of the United States Board of Underwriters.

Delegates favored the passage of a bill by the Legislature establishing a commission similar to and having the same powers of the State Railroad Commission, with power to regulate the price of water, gas and electric light in the different cities and to look after and maintain the purity of water sheds and water, and to establish a standard of purity for gas and power of electric light. The Massachusetts Commission law was accepted as a model and its adoption in this State will be urged.

The committee was given power to urge the passage of the law. It was decided for the old officers to hold over to the next meeting, the second Tuesday in September, which will be held in Sedalia.

STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

THE meeting for the organization of the Street Railway Accountants' Association of America was held at the Hollenden, Cleveland, O., March 23 and 24, 1897. The meeting was called to order by Mr. H. H. Windsor, of Chicago. Mr. Morris W. Hall, of Camden, N. J., was elected temporary chairman, and Mr. W. B. Brockway, of Toledo, O., temporary secretary. Committees on organization and nomination of officers were appointed.

The following gentlemen were present: Frank R. Greene, secretary, Chicago City Railway Company; Morris W. Hall, secretary, Camden and Suburban Railway Company, Camden, N. J.; W. W. Herrick, adjuster, Cleveland Electric Railway Company, Cleveland, O.; A. F. Walker, accountant, Allentown and Lehigh Valley Traction Company, Allentown, Pa.; William F. Ham, secretary, Nassau Electric Railroad, Brooklyn, N. Y.; D. A. Keister, auditor, Marion City Railway Company, Marion, Ind.; W. B. Brockway, auditor, Toledo, Bowling Green and Fremont Railway Company, Toledo, O.; F. S. Borton, secretary, Cleveland, Painesville and Eastern Railroad Company, Cleveland; Charles L. Wight, auditor, Toledo Traction Company, Toledo, O.; J. F. Calderwood, auditor, Twin City Rapid Transit Company, Minneapolis and St. Paul, Minn.; F. T. Pomeroy, general manager and treasurer, Cleveland, Berea and Elyria Railway Company, Cleveland; F. E. Smith, auditor, Lynn and Boston Railroad Company, Lynn, Mass.; H. J. Davies, assistant secretary and treasurer, Cleveland Electric Railway Company, Cleveland; E. S. Doud, secretary, Lehigh Traction Company, Hazleton, Pa.; H. C. McJilton, secretary, Baltimore Traction Company, Baltimore, Md.; H. L. Wilson, auditor, West End Street Railway Company, Boston, Mass.; W. G. McDole, auditor, Cleveland Electric Railway Company, Cleveland; William R. Avery, auditor, Cincinnati Street Railway Company, Cincinnati, O.; W. S. Dimmock, general superintendent, Omaha and Council Bluffs Railway Company, Council Bluffs, Ia.; P. V. Burlington, auditor, Columbus Street Railway Company, Columbus, O.; John Erhardt, assistant secretary, Cleveland City Railway Company, Cleveland; E. R. L. Tighe, accountant, Brooklyn Rapid Transit Company, Brooklyn, N. Y.; W. G. Ross, comptroller, Montreal Street Railway Company, Montreal, Canada; A. L. Linn, Jr., bookkeeper, Cleveland Electric Railway, Cleveland; J. M. Smith, comptroller, Toronto Railway Company, Toronto, Ont.; Dana Stevens, accountant, Eckington and Soldiers' Home Railway Company, Washington, D. C.; C. E. Reavis, secretary, Augusta Railway and Electric Company, Augusta, Ga.; E. D. Hibbs, auditor, Consolidated Traction Company, Jersey City, N. J.; Walter M. Barnaby, chief accountant, Brooklyn Heights Railroad Company, Brooklyn, N. Y.; C. N. Duffy, secretary and treasurer, Citizens' Railway Company, St. Louis, Mo.; Robert V. McCullough, cashier, Southern Electric Railway Company, St. Louis, Mo.; Henry H. Windsor, Street Railway Review, Chicago; Eward E. Higgins, Street Railway Journal, New York; T. E. Crossman, stenographer, New York.

The following programme was carried out, the papers being carefully prepared and eliciting considerable discussion:

Tuesday, March 23, 10 a. m.—Call to order and election of temporary chairman and secretary. "From Horse to Electric Accounts," H. L. Wilson, auditor West End Street Railroad, Boston. "Suggestions for a Standard System of Accounts: Classification of Operating Expense Accounts, and Form of Report that Will Admit of Comparison and Diffuse Information between Companies," C. N. Duffy, secretary and treasurer Citizens Railway, St. Louis. Appointment of Committee on Organization. Appointment of Nominating Committee.

Tuesday, 2 p. m., "Monthly Closing of Accounts," Dana Stevens, accountant for receiver, Belt Railway, Washington, D. C. "Transfer Tickets," Frank R. Greene, secretary Chicago City Railway. "The Relation of Accountants to Managers and Employés," P. V. Burlington, secreteary and auditor Columbus Street Railway, Columbus, O.

Wednesday, March 24, 9.30 a. m.—Report of Committee on Organization. Adoption of Constitution and By-Laws. Report of Nominating Committee. Election and Installation of Officers. "A Simple System of Interurban Accounts," W. B. Brockway, auditor Toledo, Bowling Green and Fremont Railway, Toledo, O.

Wednesday, 4 p. m.—"Naming and Standardizing Apparatus," J. P. E. Clark, general manager Binghamton Railroad Company, Binghamton, N. Y. "Depreciation," H. C. McJilton, auditor Baltimore Traction Company.

For General Discussion.—"Statistical Reports in a Nutshell." "Some Ways We Can Simplify Accounts." "Standardizing Accounts."

The following officers were elected: President, Henry L. Wilson, Boston, Mass.; first vice-president, C. N. Duffy, St. Louis, Mo.; second vice-president, J. F. Calderwood, Minneapolis, Minn.; third vice-president, C. E. Reavis, Augusta, Ga.; secretary and treasurer, W. B. Brockway, Toledo, O. Executive Committee, in addition to all of the foregoing, Dana Stevens, Washington, D. C.; W. S. Dimmock, Council Bluffs, Ia.; W. G. Ross, Montreal, Canada; E. R. L. Tighe, Brooklyn, N. Y

The afternoon of Wednesday was devoted to an extensive ride over the line of the Cleveland railways, and an examination of several power houses. An interesting feature of the meeting was the large number of accounting blanks which were exhibited by the delegates.

The meeting adjourned to convene at the time of the meeting of the American Street Railway Association, Oct. 19-22, 1897, Niagara Falls, N. Y.

HENRY ELECTRICAL SOCIETY.

The Henry Electrical Society will give its members and friends an especially interesting treat on Friday, April 2, in a lecture to be delivered at its rooms, 111 West 38th street, by Mr. W. B. Potter, on "Electric Railway Vagaries." Mr. Potter is the chief railway engineer of the General Electric Company, and is consequently so situated as to be able to present the latest developments in electric railway engineering. The lecture will be illustrated by slides.

The lecture following will be delivered by Mr. Alexander Stratton on Friday, April 23, entitled "The Use of Different Kinds of Iron and Steel in Dynamo Electric Machines."

MEETING OF TEXAS STREET RAILWAY MEN.

The street railway association of Texas met at Austin last week, and had a pleasant time. Resolutions of regret were adopted concerning the death of Mr. W. H. Sinclair, of Galveston, and against a bill giving one road free use of 2,500 feet of any other road it might connect with. Other business, chiefly of a routine character, was disposed of. The delegates present were: John H. Chiles, of the Austin Dam and Suburban Railroad; S. E. Scovill, of the Austin Rapid Transit; C. L. Wakefield, of the Elm street line, Dallas; Geo. T. Harston, of the Dallas Rapid Transit; Geo. D. Hanson, of the Fort Worth City Railroad, H. C. Chase, of the Houston City Electric Street Railroad, and D. D. Willis, of the San Antonio Street Railroad.

Maj. Ira H. Evans and other gentlemen connected with the street railroads were also present.

MARRIED

MR. H. H. KABAT, manager of the S. & B. Electric Company, of New York City, was married on Feb. 23 to Miss Hattie C. Ludwig. The marriage was a home ceremony, and several electricians were present to witness it.

LEGAL NOTES

TICKER QUOTATIONS MUST BE GIVEN OUT.

At Chicago, on March 25, Judge Horton, of the Circuit Court, overruled the motions of the Board of Trade, the Western Union Telegraph Company, the Gold and Stock Telegraph Company and the Postal Telegraph Company to dissolve the temporary injunctions restraining these parties from "detaching telegraph wires from the place of business of Harry E. Wiley, the W. A. Michael Commission Company et al., from removing 'tickers' and from cutting off or in any wise interfering with the 'supply of market information as has been heretofore supplied.'" The court said: "The Board of Trade is a private corporation. It has the same rights as other private corporations. It has the right to control and manage its private property and affairs, the same as any other private corporation has. If, however, the Board of Trade has so used or permitted such use of its property, or any part of it, that the same has become charged with a public interest, then said board has no legal right to deprive the public of the interest thus acquired, when it is sought and used only for legitimate purposes."

THE STOCK MARKET

SECURITIES STEADY DESPITE EVERYTHING.

THE United States Supreme Court having given a decision which is interpreted as a substantial condemnation of all agreements to maintain transportation rates, it might be expected that the stock market would go to pieces. But the conditions have all given evidence of a remarkable firmness, and it is beginning to be felt that for their own sake the roads will seek to maintain living rates, even without a mutual understanding. They must, unless desiring to find a lower depth of poverty than that of the last five years.

Outside of such general conditions of disturbance including the international troubles in Europe, the outlook is generally bright. There is a continued falling off in the number of business failures, trade shows improvement in dry goods, hardware, leather, shoes and agricultural implements; and even the numerous industrial strikes reflect the general expectancy of better wages.

During the past week, 10,126 shares of Western Union were sold, closing at 83; and of General Electric, 14,460, closing at 32. The decline in both is attributed to the state of the market. American Bell, however, rose two points from 223 and 687 shares were sold.

Local traction stocks and bonds are unchanged in price; Brooklyn, Buffalo and Worcester street railway securities are reported in better demand and rising. Edison Illuminating Companies remain firm and in fair demand.

PERSONAL

MR. CHAS. E. HART, who has been superintendent of the Toledo (O.) Electric Company for some time, has resigned his position to accept one as city electrician of Joplin, Mo. The employés of the company, to the number of thirty-five, called on Mr. Hart and presented him with an address expressing their regret at his departure, tendering him their best wishes for his success in his new home, and gave him several valuable presents as tokens of the esteem in which they held him.

PROF. R. A. FESSENDEN, of the Western University, at Allegheny, Pa., has been making successful tests of armor plate, for blow holes, by means of the Röntgen ray. He states that a heavy armor plate, ten inches thick, can be radiographed in two hours, and that the picture would then show any holes not smaller than an egg.

GARRET HOBART, JR., is, like his distinguished father, very much interested in practical electricity. The Vice-President of the United States inclines to electric roads and lighting plants, but his son, a bright chapple of twelve, is an expert in bell-hanging and has just applied seriously for the contract to keep the White House bells in order during the McKinley Administration. His request was made direct to the President.

MR. WALTER PHILLIPS has resigned as electrical engineer for the Illinois Steel Company, at South Chicago, to accept a similar position with the Russian-American Manufacturing Company, at Mariopol, Russia. Mr. Phillips sailed for his new post last week.

MR. J. A. RUTHERFORD, for some years past with the Westinghouse Electric & Manufacturing Company, has joined the Johnson Company, of Johnstown, Pa., as salesman in the street railway department.

MR. W. T. SCHELMERDINE, of Philadelphia, becomes president of the Queens County and New York Traction Company, and Mr. J. R. Beetem is to be general manager. The Queens County system comprises sixty miles of track.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Central Stations:

STATEMENT OF CAPITAL EXPENDITURE IN ELECTRIC SUPPLY UNDERTAKINGS.—Details of 55 supply undertakings in charge of companies and of 69 in charge of local authorities, making a total expenditure of £9,673,335.—Lond. "Elec." Feb. 26, '97.

Dynamos and Motors.

CALCULATION OF IRON LOSSES IN TOOTHED ARMATURES.—By Dr. Max Breslauer. Objecting to the use of Steinmetz's formula, when applied to the mean of the magnetization of the teeth, author calculates an applicable formula, in which the results obtained, which for several values are tabulated, are determined by calculus, thus allowing of a calculation taking care of the gradual variation from small magnetization at the surface to the dense lines of force in the middle and at the end.—"Elek. Zeitschr.," Feb. 11, '97.

Electro Physics.

MECHANICAL CONCEPTIONS OF ELECTRICAL PHENOMENA AND INVESTIGATIONS ON ALTERNATING CURRENT RESONANCE EFFECTS.—By Dr. C. Heinke. An exhaustive study on the line of the Maxwellian celebrated mechanical analogies extended so as to include resonance effects. "Elek. Zeitschr.," Feb. 4, '97.

SOME PRACTICAL ASPECTS OF ELECTRICAL RESONANCE.—By Kempster B. Miller. Paper read before the Chicago Elec. Assoc. After briefly reviewing the fundamental principles of electrical resonance, author explains how prime movers may be regulated in speed by selective resonant effects. After explaining roughly the multiplex system of telephony of Hutin and Le Blanc of Paris, he closes with the hope that the condenser may be sufficiently improved upon to make it commercially a more valuable instrument.—"West. Elec.," March 13, '97.

Lighting:

FAULTS IN ARC LAMPS.—The lamps are separated into three classes, series or constant current system, constant potential system and 500 volt, or multiple series system. Methods of inspection and finding faults in these various systems are discussed.—"Sc. Mach.," March 15, '97, from "Am. Elec."

ELECTRIC SUPPLY AT 230 VOLTS. A. H. Gibbings, in a paper read before the Nor. Soc. of Elec. Eng's, Glasgow, maintained that the town of Bradford has run this system of high voltage lamps successfully for some time.—"Mech. World and Progr. Age," March 15, '97.

Mechanical:

RAWORTH "UNIVERSAL" TRIPLE EXPANSION ENGINE AND MORDEY INDUCTOR ALTERNATOR.—Detailed description with illustrations.—Lond. "Elec. Rev.," Feb. 12, '97.

Mining:

ELECTRIC ROCK-DRILLING BY THE SOCIETE DE CHARBONNAGES DES BOUCHES DU RHONE.—By Albion T. Snell. Illustrations of several types of drills, as well as data on the length of time required for drilling.—Lond. "Elec.," Feb. 26, 1897.

Power Transmission:

INSTALLATION AT STEINAMANGER WITH 12,000 VOLTS DIRECT CURRENT.—Steinamanger, Hungary, has a 12,000 volt direct current transmission plant of 1,200 horse power. The central station is at Ikervar. A waterfall is utilized and each turbine runs two six-pole generators. The dynamos are run in series, carefully insulated from ground. They are regulated indirectly by changing the inlet of the water in the turbine. The transmission line consists of 65 kilometers of copper wire, 9 mm. in diamter, and has a drop of 10 per cent. The wires, which are bare, are fastened to double petticoat insulators on painted poles.—"Elek. Anz.," Feb. 21, '97.

Roentgen Rays.

ON AN IMPROVED METHOD FOR PRESERVING THE PROPER VACUUM IN TUBES.—By Dr. Arnold Berliner. By attaching a poor conductor, such as damp wood to the cathode and putting a layer around the tube, the vacuum can be properly preserved.—"Elek. Zeitschr.," Feb. 11, '97.

Railways:

CLARET VUILLEUMIER TRAMWAY OF PARIS.—Description of a new contact system with illustration of distribution.—"West. Elec.," March 13, '97.

COST OF ELECTRIC CAR HEATING.—A car having about six heaters consumes approximately 6 horse power to 8 horse power. Considering the 700 to 800 cars constantly kept on the road in Boston, it is found that the amount of coal required for successful heating is about 12,000 tons per year.—"Bost. Journ. of Comm. and Sc. Mach.," March 15, '97.

GERMAN ELECTRIC TRAMWAYS.—Data taken from "Elek. Zeitschr.," giving details of tramways now running, such as date of opening, system, length of line, gauge, power station, etc. Eight out of 42 stations are run by the municipalities.—Lond. "Elec.," Feb. 26, '97.

Telegraphy, Telephony, Etc.

THE PRESENT DEVELOPMENT OF THE LONG-DISTANCE TELEPHONE.—By Jul. H. West. After a general introduction on the value of the service in general, the author mentions the necessity of (1) regular service, (2) quick service and (3) a cheap one. He then discusses the distances, which may now be successfully handled and divides the country into single sections, proposing to connect the various centers, 25 in all, by single, metallic circuit, trunk lines, involving an approximate cost for Germany of about $50,000,000. The question of disturbing influences receives attention, but the author is very liberal towards the electric railroads, claiming that the telephone company should first of all have metallic circuits and only then hold the railroads responsible for disturbing influences.—"Elek. Zeitschr.," Feb. 4, '97.

IS THE REDUCTION OF TELEPHONE RATES IN GERMANY FEASIBLE?—An editorial treats this problem and it is shown that a reduction of 33 per cent. in the rates would, within a very short time, increase the demand for telephone service to such an extent that the necessary outlay for enlarging would reach such dimensions that the government could not undertake it without serious difficulties.—"Elek. Zeitschr.," Feb. 11, '97.

REPORTS OF COMPANIES

SWAN INCANDESCENT ELECTRIC LIGHT CO.

The Swan Incandescent Electric Light Company, of No. 14 White street, New York City, has applied to the Supreme Court for the voluntary dissolution of the company, and Louis B. Van Gaasbeek has been appointed referee by Judge Smyth. The following directors united in the application: Mayor William L. Strong, Edwin Einstein, Emanuel Einstein, David L. Einstein, Charles W. Spear, Morris Fatman and Felix Samson. The company was incorporated in 1882, with a capital stock of $800,000, to manufacture and sell electric lamps under the patents of Joseph W. Swan. From 1885 until two years ago the manufacture was carried on by a licensee, the Swan Lamp Manufacturing Company, of Cleveland, Ohio, and during that period the only source of revenue was the royalty. Two years ago the licensee discontinued business, and since then the company has had no income. It was unable to begin the manufacture on its own account now, and as the patents expire during the current year the directors deemed it advisable to wind up the company. It has no liabilities, and its assets are $6,903 in cash, patents and a safe.

THOMSON ELECTRIC WELDING CO.

The annual meeting of the stockholders of the Thomson Electric Welding Company will be held at Portland, Me., on April 6. This company was reorganized last April, and under the plan of reorganization the assets were divided into two parts. One part, consisting of the assets not needed in the conduct of the new business, was placed in trust to be sold, and proceeds distributed according to the holdings of trust certificates. The other part, consisting of patents, patterns and drawings, leases and royalty contracts, manufactured stock and the balance of assets necessary to the development of the business, was retained by the reorganized company. There has been paid to date from the proceeds of the sale of the assets in the trust $2 per share, and it is expected that $2 per share more will be paid upon the final liquidation of the trust. The present stock is receiving semi-annual dividends at the rate of 6 per cent. per annum. A contract has been recently negotiated with the French government for some of the apparatus manufactured by the company. The company has cash assets amounting to over $75,000, and the total amount of its cash liabilities is nominal, being but $300.

TRADE NOTES & NOVELTIES

SOME INTERESTING FACTS ABOUT PLATINUM.

A RECENT importation of crude platinum consigned to Baker & Co., the platinum refiners of Newark, N. J., contained a nugget which is believed to be the largest ever exhibited in this country. This nugget illustrated herewith, is as usual of irregular form; it measures approximately three by two by three-quarter inches and weighs nearly two pounds. It is now on exhibition at the New York office of the above named firm, No. 121 Liberty street, where it is attracting the attention of metallurgists and the admiration of all who are interested in mineralogical curiosities.

It may be of interest to the general reader to learn that platinum ore is a most complex mixture of mineralogical species and includes not only a number of heavy reguline ingredients, such as platinum, iridium, osmiridium, palladium, rhodium, and gold, but also certain non-metallic species, notably chrome iron ore, magnetic oxide of iron, zircon corundum, and frequently diamonds. Because of its complex composition the ore has received the surname of "polyxine."

The heavy reguline ingredients are rarely found except in the form of small detached granules; the most notable exception to this rule being a nugget of Russian ore now in the Demidoff Cabinet in St. Petersburg, weighing between seven and eight kilograms. The average yield of metallic platinum from the ore varies between 50 and 80 per cent.

Platinum was first discovered in a Spanish mine of South America, early in the sixteenth century from which source it received its name "platina del Pinto" (little silver from the river Pinto). The ore is now found in various parts of the world, but the richest deposits are those of the Ural mountains which have been worked under the supervision of the Russian government since 1828.

The platinum of commerce is obtained entirely from alluvial deposits at depths varying from six to forty feet. The sand and gravel of former river beds are subjected to a series of screenings and washings to effect the separation of the ore; most of this labor in Russia being done by women. The yield of the ore per ton of sand seldom exceeds six grams. Sand yielding less than three grams per ton is rarely worked with profit. All Russian ore pays a government tax of three per cent., in the form of the ore mined, and any person possessed of the ore without a license is subject to imprisonment and confiscation of the metal.

Platinum occupies a unique position among metals. When pure and in compact form, it is tin white in color. It is the heaviest and has the highest fusing point of any metal in commercial use unalloyed. Its specific gravity is 21.5; it is therefore twice as heavy as silver and nearly three times heavier than cast iron. A temperature of nearly 1,800 degs. Cent., or 3,300 degs. Fahr., is necessary to fuse the metal, hence it is unaffected by temperatures attained in the hottest of blast furnaces. This valued property has led to the extensive use of the metal in such furnaces as an important part of an instrument for measuring temperatures.

Platinum ranks fourth as a conductor of heat and sixth as a conductor of electricity among metals. It expands and contracts, under variations of temperature, less than any other metal, and because of this fact, its high fusing point and nonoxidability, platinum is the only metal that can be successfully sealed into glass vacuum apparatus.

It is almost as soft as copper and ductile as gold. It can easily be rolled into sheets so thin that a thousand of them piled on top of each other would not exceed an inch in height. It is daily drawn into the form of wire not exceeding one-thousandth part of an inch in diameter.

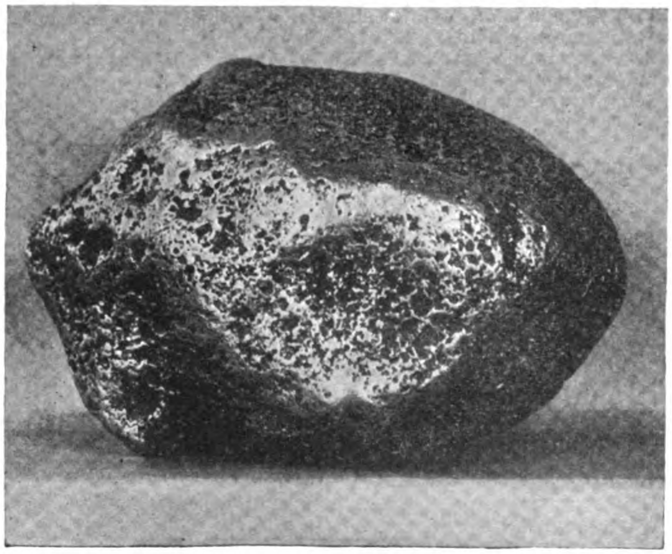
For use as "spider lines" in optical instruments platinum is drawn by a special process to diameters as small as sixty millionths of an inch. Such wires are nearly invisible to the unaided eye—a strand of it of sufficient length to encircle the earth at the equator would only weigh forty-six ounces.

Platinum is not attacked by any single ordinary acid and is not changed by air, water or steam at any temperature. Because of its many peculiar qualities it is one of the most valued metals made available to man's wants and notwithstanding its excessive cost, the present market price being $14 per ounce, its yearly consumption is rapidly increasing.

The chemist would be practically helpless in much of his work without the aid of platinum. In the words of Liebig, the eminent German chemist, "Without platinum it would be impossible, in many cases, to make the analysis of a mineral. The mineral must be dissolved, and it must be first rendered soluble, or prepared for solution. Now vessels of glass, of porcelain and of all non-metallic substances are destroyed by the means we employ for that purpose.

Crucibles of gold and silver would melt at high temperatures, but platinum is cheaper than gold, harder and more durable than silver, infusible at all temperatures of our furnaces, and is left intact by acids and alkaline carbonates. Platinum unites all the valuable properties of gold and of porcelain, resisting the action of heat and of almost all chemical agents. Without platinum the composition of most minerals would have yet remained unknown." Platinum is pre-eminently the metal of the chemist, both in analytical and industrial operations. No chemical laboratory is complete without a varied assortment of platinum apparatus and fortunes are annually invested in platinum retorts for the commercial concentration of oil of vitriol; chemical operations alone consumed until within a few years the bulk of the metal produced.

The dental and electrical industries which have progressed so rapidly within recent years are said at the present time to consume, in the United States alone, more than half of the world's supply of platinum. In the manufacture of artificial teeth, platinum pins are used to fasten the porcelain teeth to the supporting plate during the process of baking the porcelain. Platinum is the only metal available for this purpose because of the high temperatures required. It is also used in the form of thin foil for taking the impression of cavities in natural teeth which are to be subsequently filled with baked porcelain and still more extensively in the form of muffles to protect the baking porcelain from direct contact with the fire or the products of combustion which would discolor the porcelain. The consumption of platinum in the dental industry of this country for 1897 will probably be a larger quantity than ever consumed before in a single year in that industry.



A TWO-POUND PLATINUM NUGGET.

Platinum has, as is well known, played a most important part in the development of the incandescent lamp. It was early used as the light-giving body of the lamp, but subsequently yielded this position to carbon because of the latter's higher electrical resistance, higher fusion point and lessened cost. Although now occupying a less prominent position in the modern lamp it is nevertheless one considered as essential in the construction of a successful lamp. Many devices have been tried to avoid its use but without commercial success.

Radical changes in the construction of incandescent lamps have reduced the consumption of platinum per lamp enormously, but on the other hand the production of lamps has increased in greater proportion and the aggregate consumption is greater than ever before in that industry. The telephone, telegraph, and, in fact, almost all of the electrical industries, are yearly making heavier demands upon the limited supply of the metal. Physicians require it in cauteries and surgical instruments where extreme cleanliness is important. Platinum is extensively used in the finer grades of jewelry and a number of its salts continue in favor as superior to anything else for producing dead black surface effects upon silverware.

In photography the present fad for "platinotypes" illustrates a comparatively recent demand for certain salts of platinum. Platinum salts are also used by many photographers in preference to gold salts in toning silver prints. The platinotype is a special favorite because of the simplicity of the process of production, the artistic effects produced and the permanency of the picture.

To enumerate the many and varied uses of platinum and its salts would extend this article beyond reasonable limits. Suffice it to add that the latest application of its peculiar properties is due to Röntgen's discovery that certain invisible rays of energy when allowed to fall upon one of the double salts of platinum (barium-platino-cyanide) renders the same luminous so that a screen of paper covered with this salt and exposed to the action of Röntgen rays serves for the production thereon of a shadow picture of many objects of variable density which may be interposed between the screen and the source of the Röntgen rays. Metallic platinum is also a most important factor in the construction of Röntgen ray apparatus, both as a means of conveying electric energy into the vacuum chamber and as a source of excitation of Röntgen rays. Thus in this most recent development of the agencies for anatomical and physical research platinum plays a most important part; one which largely enhances its utility and value to mankind.

G. E. 1897 FAN MOTORS.

THE General Electric Company will this year, as last, place on the market fan motors for both alternating and direct currents designating them as G. E. fan motors, '97 model. They retain the compactness and simplicity of the '96 models, with certain improvements.

The alternating current fan motor, shown in Fig. 1, is made for operation on currents of either 60 cycles or 125 cycles. The speed is regulated by an inductive resistance operated by a three-point switch giving full speed and half speed and cutting off the current at the third point. The presence of this switch allows of direct connection of the motor to the circuit without the use of a socket and plug connection—an appreciable convenience.

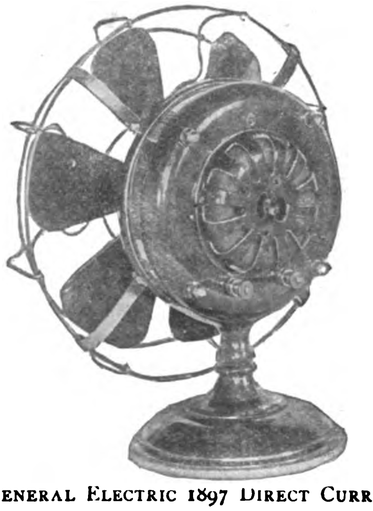


Fig. 1.—General Electric 1897 Direct Current Fan.

The electrical design of this motor follows closely that of the '96 model. The field core is a ring of iron punchings with inwardly projecting poles carrying the field coils. The armature is a laminated core through which, near the periphery, are run bare copper rods riveted to copper discs at each end the core.

There are neither commutator nor brushes, rotation being produced by inductive action. This permits the core to overhang the bearing to such a degree that, together with the fan, a balance is effected and the motor has but one long bearing, provided with a self-oiling device, so that it does not heat. The inconvenience of flying oil is entirely done away with by this method. The fan is 10 inches in diameter.

The direct current fan motor, Fig. 2, also has but one self-oiling bearing. The commutator is completely enclosed and the small carbon brushes are encased in tubes which may be readily unscrewed for inspection. A regulating resistance and switch on the base allows of changes in the speed of the motor. The fan is 12 inches in diameter.

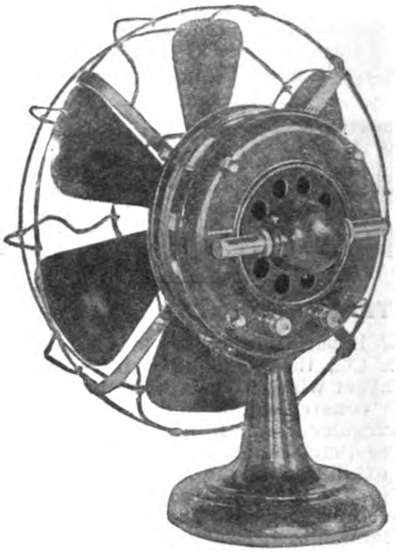

Fig. 2.—General Electric Alternating Current Fan.

The finish of all '97 fan motors and fans is black japan, the guard, bindings posts, nuts and screws being nickelled.

EMERSON "1897 MODEL" INDUCTION DESK FANS.

THE accompanying engravings illustrate the "1897 model" Emerson induction desk fans for alternating circuits. In external appearance the 1897 models of induction motors will present the same general design as the well-known "Meston" motors, which have become known in almost every part of the world where the alternating current is used.

The finish, however, will be slightly different. The illustrations, Figs. 1 and 2, show the fan motor in perspective and in section respectively. F indicates the oil well, showing the felt packing; G the oil hole; H, the double bronze bearing, and I, the switch handle. The armature, in common with all motors of the induction type, has no insulation, and it is, therefore, impossible to burn out.

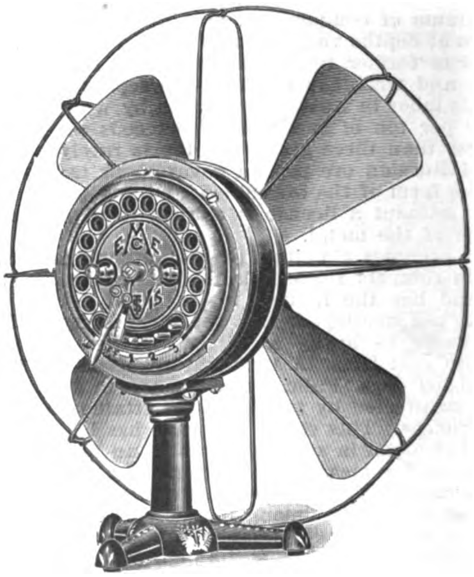

Fig. 1.—Emerson Alternating Current Fan.

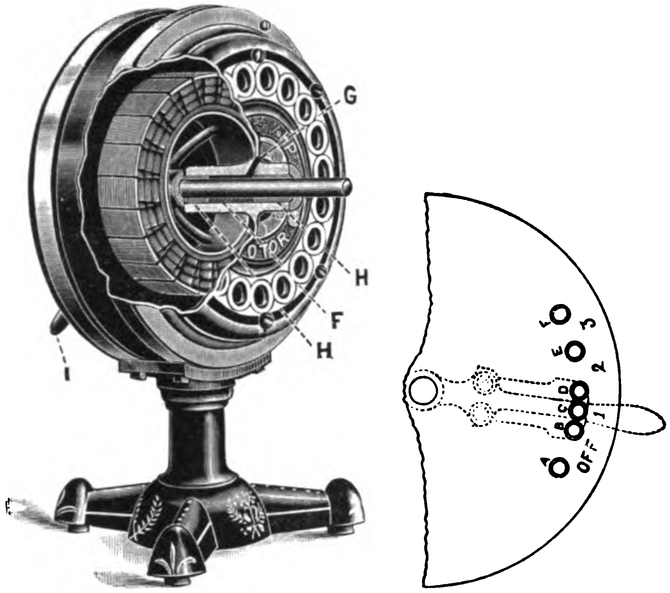
The regulating switch, Fig. 3, comprises six contact pins and a contact lever, to make the proper connections; and there are four stops, namely: off, one, two, three. When the handle is opposite "stop" the switch makes contact with pins A and B, and A being the black pin and having no connection, opens the circuit.

When opposite No. 1, the lever makes contact with pins B, C and D, and the motor starts and runs up to full speed, and (for the 12-inch fan motor) takes approximately 65 watts.

When opposite No. 2, the "economy stop," the lever makes contact with pins D and E, and the motor will not start; but if running at full speed, will continue to run at this same speed and take only approximately 45 watts, or the current of less than one lamp.

The motors are double bearing motors, combining the advantages of the perfect alignment of a single bearing motor with the perfection of operation and wearing qualities, which can only be secured by a double bearing. The bearings are bronze and the shaft steel, a combination which is unexcelled for wearing qualities, and the design and proportions are carefully worked out to withstand the speed and wear.



Figs. 2 and 3.—Emerson Alternating Current Fan.

A large chamber has been left between the two bearings for lubricant, and this is filled with a special graphite lubricant, which is supplied to the shaft as required by a strip of the finest felt. This lubricant will not throw oil, and will last indefinitely.

The fan is a very important part of a fan motor, and must be carefully and correctly made to insure smooth running. The pitch of each blade must be just right; it must be in perfect running balance in all its parts. The Emerson Company were the first to support the blade rigidly, and the first to use a rigid fan hub, which cannot be bent out of shape. Many of these points are small in themselves, but it is the perfection of each detail which makes a perfect motor.

The 12-inch Emerson motors take 45 and 50 watts.

THE FLAGG IMPROVED MICA INSULATING JOINTS.

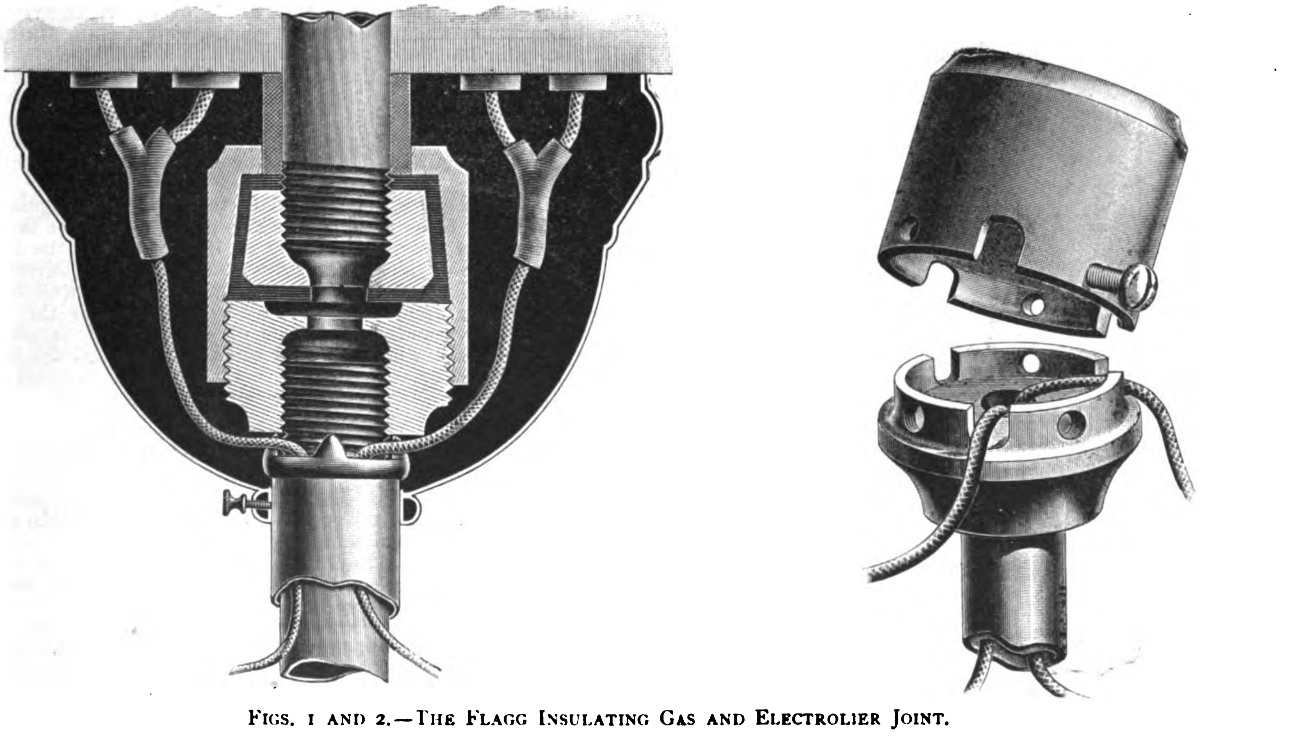
Perhaps more "troubles" are developed in fixtures than in any other part of electric house circuits, and a fruitful source of annoyance are defective joints. Messrs. Stanley G. Flagg & Co., of North Nineteenth street, Pennsylvania avenue and Hamilton street, Philadelphia, have brought out the "Flagg" improved mica insulating joint which possesses a number of excellent features. Our illustration, Fig. 1, shows the joint detached and Fig. 2, as applied to a combination fixture.

The joint for combination fixtures is so constructed that the "grounded part" is concealed in such a manner as to allow an insulated tube or ring to be placed over the gas pipe extending from the wall or ceiling surface into the top section of the insulator resting on the mica insulation, thus preventing the electric wires or taps from coming in contact with either the gas pipe or the grounded part of the joint. This dispenses with unnecessary tubes or tubing, which at present are required to be placed over the electric wires or taps extending from the wall or ceiling surface below the grounded part of the joint, and requiring an extra large canopy or shell to conceal the same, which makes an unsightly, bulky appearance, and greatly detracts from the beauty of the fixture.

This joint is capable of withstanding such strains as would be necessary in straightening the fixture after it is hung in position, without danger of causing a leakage of gas or injuring the insulated part.

The joint for electric fixtures is constructed so that when the joint is taken apart the electric wires or mains in the electrolier may be brought through the bottom part of it. The screws which connect the upper and lower section are so placed that the joint may be connected and disconnected after the fixture is in position, whether a plain or telescoped canopy is used, and an electrolier may be easily adjusted to an outlet in a corner or in an inconvenient place.

By the use of this joint the grounded part is thoroughly insulated, and it is not necessary to bring the circular loom tubing or the covering of the wires to the bottom of the joint. As will be noted in the engraving, this is cut close to the ceiling; this gives complete protection on the upper part in connection with the gas pipe and removes all liability to ground, and by the use of this joint the expense for extra tubing is done away with, and at the same time a much smaller canopy can be used.



Figs. 1 and 2.—The Flagg Insulating Gas and Electrolier Joint.

These joints have been approved by the inspectors in all the leading cities, as also by the United States Government and by the National Board of Fire Underwriters.

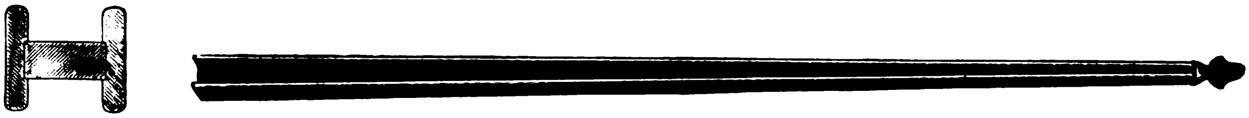
THE BROWNLEE BUILT-UP WOODEN POLES.

A DECIDED novelty which has commanded the immediate attention of electric railway, lighting and other companies, owning distributing conductors, is the Brownlee built-up wooden pole illustrated in perspective and in cross section in the accompanying engravings.

The pole is built up of three pieces, which construction gives it great strength and stiffness, while at the same time lending to the pole a handsome appearance. The construction also results in low cost.

The lasting qualities of these poles must be apparent. The construction permits of the use of seasoned timber which takes the paint well and, of course, lasts much longer than unseasoned stock. For ordinary purposes the Brownlee Company use a wood preserving paint, containing a large amount of creosote.

Messrs. Brownlee & Co., of Detroit, Mich., the makers of these poles, also furnish poles which have been creosoted under pressure. While such are more expensive, they are claimed to be superior to iron poles, and, under ordinary conditions, to last from thirty to fifty years. These creosoted poles absorb no moisture, and this, in connection with the fact that creosote is a non-conductor, adds largely to the insulating properties of the pole.



Figs. 1 and 2.—The Brownlee Built-Up Wooden Pole for Railway and Lighting.

Messrs. Brownlee & Co. have been in the pole business continuously for twenty-seven years, and were the originators of the "octagonal pole," now so generally used. Their plant covers over 30 acres. They own large tracts of standing timber in Northern Michigan and Canada, cut it themselves and manufacture it at their works in Detroit. Their facilities for shipping by both rail and water are all that could be desired.

THE CHAPMAN VOLTAGE REGULATOR FOR DIRECT AND ALTERNATING CURRENT GENERATORS.

THE high watt incandescent lamp is necessarily expensive in the item of power and the low watt lamp is also expensive in the item of lamp renewals when the regulation is poor.

PORTLAND ME.
U.S.A.

Chapman Voltage Regulator.

But the low watt lamp combined with perfect regulation is the perfection of economy with incandescent electric lighting. Every intelligent station manager fully appreciates this fact and a good voltage regulator is the urgent demand of the times, and this demand is aimed at in the new Chapman voltage regulator, which the Belknap Motor Company, of Portland, Me., are now putting on the market. A large number of these have been put out and are in practical operation and have proved to be all that could be desired. The regulator is a magnetic device and acts very promptly, being only limited in quickness of action by the ability of the generator it may be regulating to respond to change on a field rheostat.

The device, illustrated in the accompanying engraving, is essentially a field rheostat whose operation is entirely automatic. The moving of the rheostat arm is accomplished by the action of a working solenoid, and the actions of the working solenoid are determined by those of an auxiliary solenoid which operates a set of contacts that control the admission of current to the sections of the working solenoid. The working solenoid is differently wound and is composed of four distinct coils, two of which have a small continuous current flowing through them, in electrical opposition to each other; the contacts close the circuit of one or the other of the remaining coils and so neutralize the action of one of the continuously acting coils.

This manner of connecting secures a rise of magnetism in the iron core of the solenoid whenever a break occurs at the contacts and so avoids any injurious sparking at the contacts that would naturally occur by the magnetic discharge of the core. The arrangement completely neutralizes the induction discharge, and no induction spark can occur. All of the usual objection to contact points is therefore entirely removed.

The entire work of the auxiliary solenoid is to move a lever arm with contact attached through a short space of say one-thirty-second inch, and a very slight change of voltage is sufficient to do this. It is often desirable to have the voltage at the generating station rise a little with the load so that it becomes greater than the voltage at the distributing center where it remains constant with changes of load. This result is aimed at in the compound winding of the generators, but, in most cases, is far from securing the result desired on account of changes of speed, which no compounding of the generator can compensate for. The compounding of the auxiliary solenoid, however, secures the desired result, and a plain shunt wound generator becomes just as effective as a compound wound generator. The use of the regulator enables the old style alternating current generators having no compound coils to do just as good work as the more modern apparatus. Thus many machines that have been discarded as out of date can be utilized with good effect. The same is also true of direct current generators.

As to the energy consumed in the Chapman regulator, it is so small as to be negligible. The operation of the large working solenoid only requires 60 or 70 watts, and the rheostatic part of the device is concerned only with the current in the shunt winding of the generator which, as is well known, is only a very small percentage of the output of the machine; so that the regulator may be operated on a machine of 150 kilowatts with an extra expenditure of energy, not exceeding 1-4 horse power.

H. W. JOHNS MFG. CO.

The announcement of the removal of the H. W. Johns Manufacturing Company from their 87 Maiden Lane offices to the new Woodbridge building, at William and John streets, serves to call attention to the enormous development which has taken place in the asbestos industry since its introduction in this country. Mr. Johns has been called the "Apostle of Asbestos," and the title has been well earned, for not only was he the pioneer of the industry in America, but all the various asbestos firms of Europe are indebted for what success they may have achieved to the development of the possibilities of the material to Mr. Johns' insight, study and enterprise.

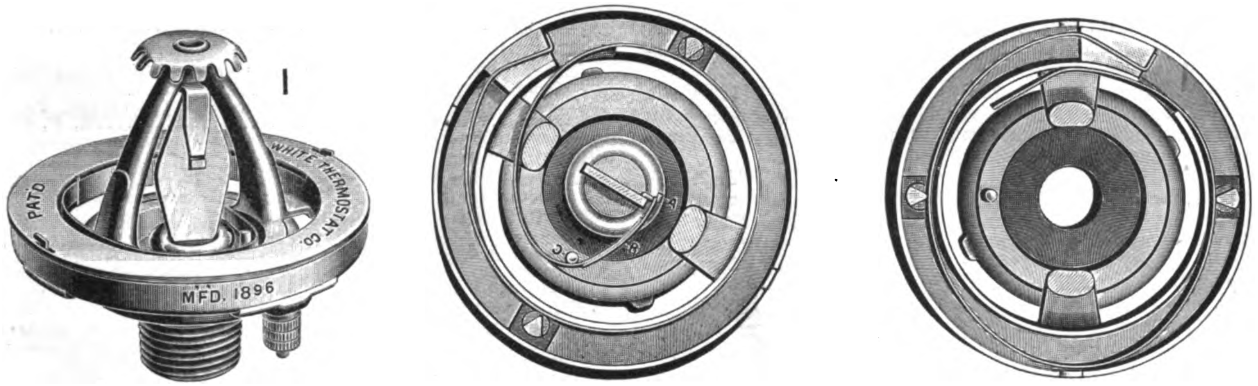
These qualities have built up the H. W. Johns Manufacturing Company to the largest asbestos house in the world, and we heartily wish it continued success.

PURITAN ELECTRIC COMPANY are moving from one floor to another in the American Tract Society building, Nassau street, New York City, in order to get better accommodation, and will be found hereafter comfortably settled in room 733 on the seventh floor.

THE COMBINATION WHITE THERMOSTAT AND GRINNELL SPRINKLER, AND INSULATED WIRE SUPPORTER.

EVERY building equipped with automatic sprinklers in order to obtain a reduction in rate of insurance must maintain an approved automatic fire alarm system or a reliable watchman and watch clock. The difference in expense and protection is greatly in favor of the former; consequently where an automatic system is employed a watchman can be dispensed with.

The White Thermostat Company, of Providence, R. I., in order to meet the demand for a simple and reliable system of fire protection, brought out a short while ago, a combination of the White thermostat with the well-known Grinnell sprinkler, thus combining in one apparatus both the elements essential to fire protection.



FIGS. 1, 2 & 3.—COMBINATION WHITE THERMOSTAT AND GRINNELL SPRINKLER.

The engraving, Fig. 1, shows the combination, and Figs. 2 and 3 show the inner parts in two views, the former showing the position of the spring before, and the latter after the release of the spring by heat.

The active agent is a coiled spring composed of two parts soldered together at B, with the same quality of fusible solder as that used to hold the sprinkler closed. One end of this compound spring is hooked to the movable part of the sprinkler, the part called, in the case of Grinnell sprinklers, the "Strut," which has to be removed to allow any water to flow. The spring can therefore be released in two ways—by the melting of the solder at B or by the opening of the sprinkler, releasing the spring at A. Either one of them will allow the spring to come into contact with the two v-shaped electrodes inside the thermostat, as shown in Fig. 3, and this gives the alarm.

The first important result of this construction is that the sprinkler cannot open and discharge water without instantly giving an alarm, for no water can flow until the "strut" falls out, and this releases the end of the thermostat spring at A.

The second result is that when a dangerous heat developes the thermostat will give an alarm before the sprinkler opens. An incipient blaze may be put out with chemicals before the sprinkler throws any water. The reason is, that although the solder used for the thermostat spring and the sprinkler are the same, the former is attached to very thin pieces of metal and is exposed on all sides to the air, while the latter unites pieces of considerable thickness, and has besides, the sprinkler, pipe, and water in the pipe, to draw away heat and retard the operating point. This radiation of heat away from the solder of the sprinkler makes a difference between the operating point of the device and that of the sprinkler from 40 to 60 degs. in favor of the thermostat, heat rising 1 deg. per second. Numerous tests before the New England Insurance Exchange show this. This feature of greater sensitiveness is a great point in favor of the White thermostat; but of the first importance is the fact that no sprinkler can open without instantly giving an alarm.

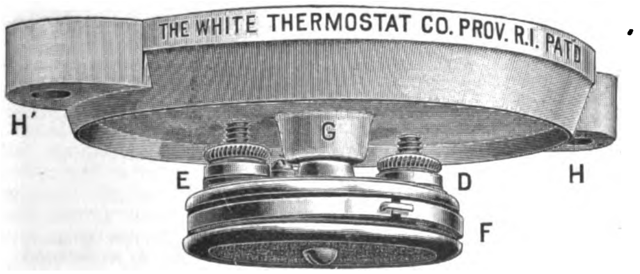


FIG. 4.—WHITE THERMOSTAT FOR USE IN UNSPRINKLED PLACES.

Sprinklers are opening occasionally on account of some fault of construction, by blows, freezing of water, and from various other causes not undue heat. This device, by giving immediate notice of such event, insures against anything but trifling water damage in such cases.

This ingenious combination has already proved its value in a number of instances. Where it is desired to install a thermostat alarm system without sprinklers the thermostat shown in Fig. 4 is well adapted. In this device, the porcelain base G is fastened to the ceiling by screws passed through holes H and H^1. The strap F is raised from the body of the thermostat by being soldered, not directly to the wall of the thermostat, but to a thin piece of metal raised on knees from the case. This allows air to circulate both behind and in front of the releasing part of the thermostat, thereby reducing radiation of heat to a minimum and increasing the sensitiveness of the thermostat. The sharp edge of the porcelain disc, as shown in the engraving, is designed to shed water from the device, thereby avoiding water crosses and consequent false alarms.

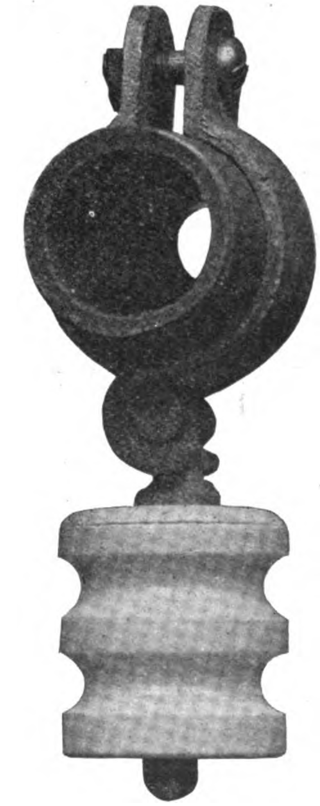

FIG. 5.—THE "JUSTIT" WIRE SUPPORTER.

Both this and the device described previously have been approved by various insurance underwriters' associations.

Another specialty of a very useful character, made by the White Thermostat Company, is the insulated wire supporter intended to be hung from pipes, shown in Fig. 5. This device termed the "Justit," consists of a brass clamp which is loose-jointed so that its two parts are readily and securely held in place by a single screw. The porcelain knob insulator is suspended by a split pin, the lower edges of which have offsets which hold the insulator in position. By pinching the spring pins, the insulator can be readily inserted in place or removed when desired.

ADVERTISERS' HINTS

THE VARLEY DUPLEX MAGNET COMPANY have removed from East Houston street, New York, to new quarters at 138 Seventh street, Jersey City.

A. L. BOGART, 22 Union Square, New York, says his dynamo-electric gas lighter is popular, reliable and a cheap substitute for matches.

F. M. LOCKE, Victor, N. Y., illustrates his "ad" this week with a cut of his insulator pin. This pin has been used on some very high voltage transmission lines and is proving itself strong and practically indestructible.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, 1112 Samson street, Philadelphia, are advertising the Midget Jr. types of "I-T-E" circuit breakers. These devices have been found so thoroughly reliable wherever tried that the company have received a goodly number of supplementary orders as well as first orders.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., call attention to their system of testing every engine before leaving the shops. With a record of such economy tests the buyer knows exactly what he has to deal with and may accept or reject the engine, as he desires.

THE ELECTRIC ARC LIGHT COMPANY, 687 Broadway, New York, have something to say on the evolution of lighting methods.

HERMAN A. STRAUSS, E. E., 54 Maiden Lane, New York, makes a specialty of power-transmission work in all its branches.

THE GENERAL ELECTRIC COMPANY'S fan motors for 1897 are now on the market. The special advantages claimed for them are no heating, no oil-throwing, only one bearing, self-oiling and variable speed.

THOS. HILL, JR., 81 Pine street, New York, is the Eastern representative of the Ahlm-Edwards Electric Company, Medina, O.

THE WARD-LEONARD ELECTRIC COMPANY, Hoboken, N. J., are advertising automatic rheostats of the "I. A." type.

J. P. WILLIAMS, 39 Cortlandt street, New York, has a large variety of ceiling, wall and desk fans to suit all voltages.

THE COX-THERMO ELECTRIC CO., of St. Albans, England, cable that they have recovered from the effects of their recent fire and are now in good shape to fill all orders promptly.

NEW YORK NOTES.

WENDELL & McDUFFIE, managers, 26 Cortlandt street, New York, have issued a very clever and attractive circular in regard to the Hascall steam generator which they handle. The matter includes a letter from the Standard Rock Candy Company, of Brooklyn, testifying to a saving of from 20 to 25 per cent. in fuel, which will pay for the generator within the first year.

WESTERN NOTES

FLOOR GLASS INSULATORS.—As will be noted in the advertising columns of this number, the Electric Appliance Company are making a special drive on a lot of floor glass insulators which they are anxious to dispose of. The users of these insulators will find it to their advantage to get prices from the Electric Appliance Company, on what they have in stock.

K. McLENNAN & CO., sole manufacturers of the celebrated Gale's Commutator Compound, stated to a representative of this journal recently that there are few power and central stations as well as isolated plants, throughout this country, as well as in Canada, that are not at this time using Gale's Commutator Compound. They will, however, continue to furnish free sample sticks to the few who have not tried it. They have in contemplation the publication of "two thousand reports" from users, and they ask all who are now using this compound, who have secured same from their supply house and have not reported to them the results of their trial, to do so at once so that their report may be inserted in the forthcoming pamphlet. Free samples of Gale's Commutator Compound can be obtained of all supply houses.

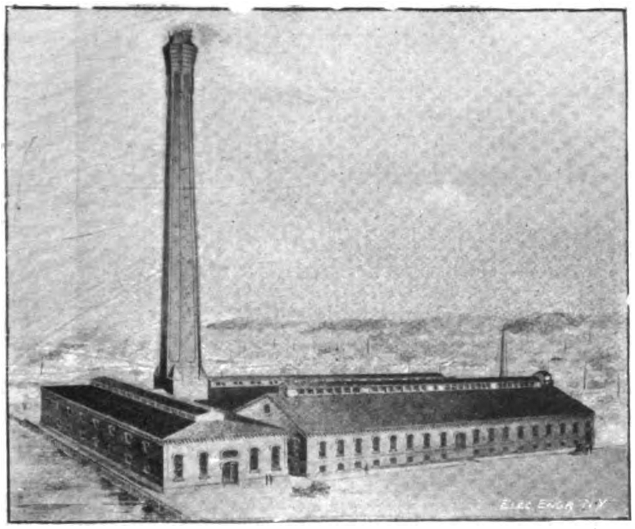
ELECTRIC LIGHTING

THE NARRAGANSETT ELECTRIC LIGHTING CO.—THE EVOLUTION OF A TYPICAL COMPOSITE STATION.

BY JOSEPH WETZLER.

THE Narragansett Electric Lighting Co., Providence, R. I., was established by Edwards H. Goff in January, 1884, who brought from Lynn a single 25-arc light Thomson-Houston dynamo and operated it from an elevator engine in the cellar of one of the business blocks on Westminster street. He hung three or four lights in the corridors of this building and one at the street door. In the succeeding April he secured a city contract for 75 arc lights, and immediately proceeded to install a small steam plant of two 100-horse-power return tubular boilers, four 50-horse-power Armington & Sims engines, and eight 25-light Thomson-Houston arc dynamos. Meanwhile, he organized under a Maine charter, but in September of 1884 he secured a Rhode Island charter, with a capital stock of $100,000, and converted the whole property into the Rhode Island corporation. The plant was about half completed and the company had customers for ten commercial arc lights and seventy-five city lights, when, after three or four weeks of negotiation, a controlling interest was acquired by the present management, and the final papers were passed and delivery made on Friday, November 13, 1884.



THE NARRAGANSETT ELECTRIC LIGHT STATION, PROVIDENCE, R. I.

The new owners proceeded at once to complete the plant and develop the business. Considerable additions were made from year to year until 1888, when a rival company, known as the Rhode Island Electric Light Company, was absorbed by the Narragansett Electric Lighting Company. A new station was erected to receive the business of the two then existing stations. Not a single piece of steam machinery was removed to the new station. The steam plant installed was entirely new and is described later in this article. Every piece of electrical apparatus that was then in use has disappeared and been replaced by the most modern equipment. The steam plant which, when the present management assumed control, was 150 horse power, is now 7,500 horse power, and the electrical equipment, which was then a little over 100 kilowatts, is now more than 4,000 kilowatts. In 1884 the number of poles was 125, with about three miles of wire, while to-day there are 7,500 poles and 1,500 miles of copper wire.

BOILERS, FEED WATER HEATERS AND ECONOMIZERS, Etc.

Realizing that as much, if not more, can be saved in the proper equipment and management of the boiler room as in the engine and dynamo room, the company have spared no pains or expense to bring their boiler plant up to the highest point of efficiency according to the latest practice of the art.

In the construction of the boiler room or rather building, special pains have been taken to insure solidity and fireproof qualities. As shown in the sectional view on page 363 the walls, 32 inches thick, of brick, rest on piles upon which is built a heavy foundation of concrete. The boiler fronts likewise rest on heavy foundations erected on a double row of piling running through the center of the boiler room. The steel roof trusses are covered with tile at the sides and the monitor with glass, so that ample light is afforded. The trusses are made extra heavy so as to support the weight of the steam pipes.

The equipment of the boiler room consists of ten boilers of 300 horse power each. All of these are of the water tube type, six being of the Babcock & Wilcox make and four built by the National Water Tube Boiler Company, of New Brunswick, N. J. The National boilers have open hearth cast steel headers, which this company were the first to introduce in this country.

Situated in the rear of the boilers as shown in the sectional view of the boiler room on page 363 are five Green economizers, one for each pair of boilers, as shown in the plan view on that page. These economizers have about 5½ square feet of heating surface per horse power of boiler and deliver the water to the boilers at an average temperature of 250 degs. The scrapers of the economizers are operated by a 10 horse-power motor.

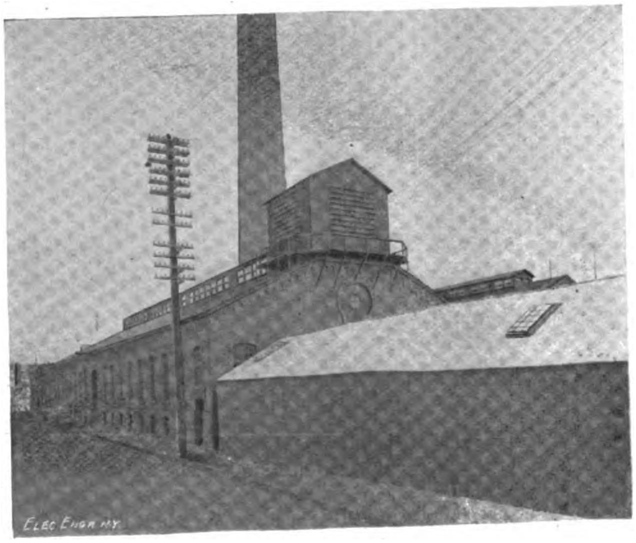
As shown on the plan, the boilers are arranged in three pairs on each side of a central aisle from which the firing is done. Space has been left for additional boilers when these shall be required, as indicated in outline on the plan.

The fuel employed is a mixture of New River semi-bituminous coal and anthracite dust. The firing is done by hand.

The draft is controlled by a Locke damper regulator and the boilers are fed by a duplicate set of Worthington pumps.

PIPING AND VALVES.

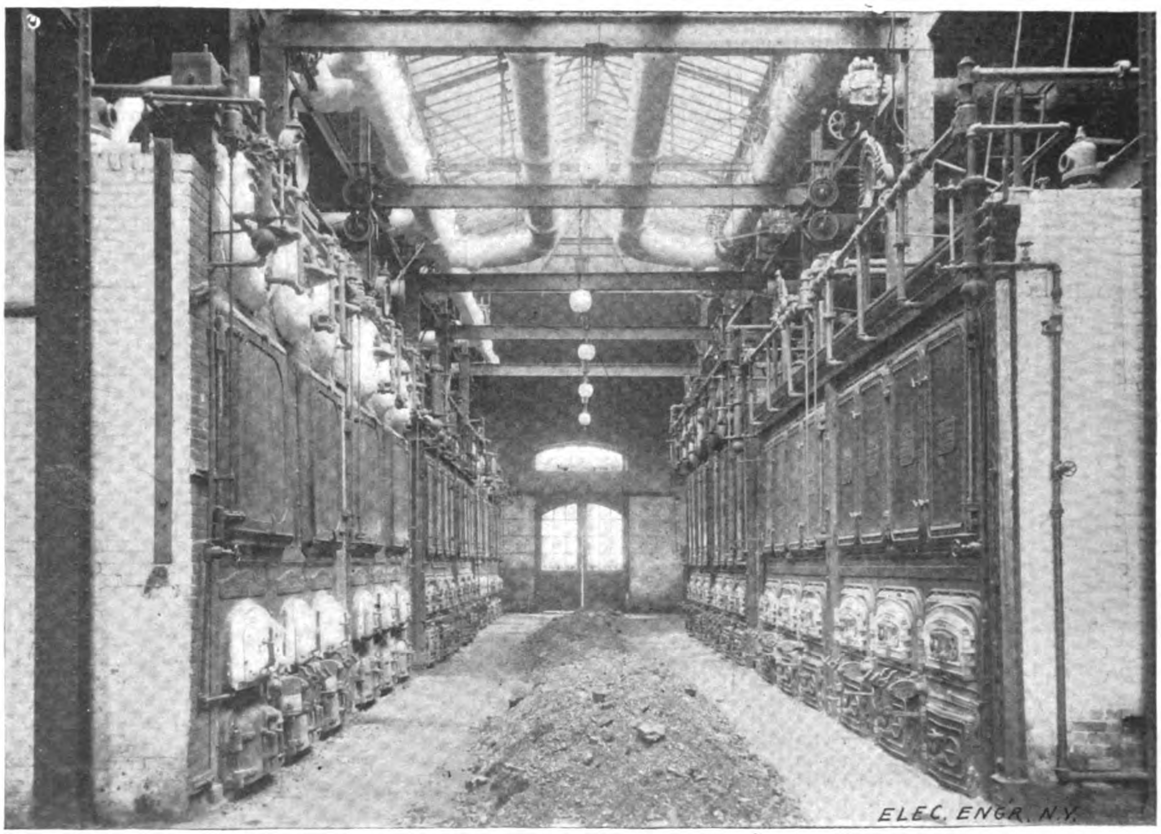
Having in mind the fact that the integrity of the steam distributing conduits within the station is quite as important a matter as the integrity of the outside electrical circuits, the Narragansett Company gave particular attention to the design of the piping in its station; indeed they were forced to adopt extraordinary means to meet their requirements. Having determined upon high boiler pressure, it was deemed advisable in the original installation, to employ wrought iron pipe, riveted and flanged. It was soon found, however, that even with the best attention this type of pipe could not be kept steam tight, and it was finally determined to take a new departure in stationary steam engine practice and to install steel piping. This was done and the result has been most satisfactory in every way, not a leak being visible anywhere throughout the station.



THE WIRE TOWER.

The arrangement of the piping is shown on the plan. As will be seen, each boiler feeds into a line of pipe running directly above the boiler heads and each of these lines is tapped at the center by two mains which run parallel and join at the end of the boiler room delivering their steam to the large 20-inch main steam pipe leading past the chimney to the engine room. Just after passing the chimney, the pipe is deflected downwards below the engine floor so that the steam is well drained before entering the engines above. The main steam pipe as it comes from the boiler room is 20 inches in diameter and ¾ inch thick. From this are supplied two main branch pipes, each 16 inches in diameter and ⅝ inch thick. This piping is made of open hearth cast steel, with the joint cast right on the pipe. As shown on page 364, the piping is provided with very heavy flanges, heavily bolted with male and female joints and copper ring gaskets, the latter being furnished by the Taunton Locomotive Works. All the steel piping is the product of the Penn Steel Casting and Machine Company, of Chester, Pa., and is tested up to 1,000 pounds pressure per square inch. As the boiler pressure carried at present is 165 pounds, there is thus an ample margin of safety. As shown on page 363 all the steam piping in the boiler room is suspended from the roof trusses.

All the valves controlling the steam in the main piping are of the Chapman type with an extra heavy pattern of gate. They are provided with bronze valve and seat, with outside screw and yoke and bypass.



Boiler Room, Narragansett Electric Light Station, Providence, R. I.

The throttle valves controlling the engines are peculiar in that they are of the globe type with bypass. Their construction will be readily understood from the engraving on page 364, which gives a sectional view of the valve.

THE CHIMNEY.

The great chimney which carries off the waste gases after they have passed through the economizers is one of the land marks and sea marks of Providence, being 260 feet high. Its construction is illustrated on page 364. It rests on 231 piles each 50 feet long, which are covered by a base of concrete 48 feet square and 7 feet 6 inches thick. The weight of the chimney is 4,600 tons and the pressure per square foot of foundation is 2 tons, and per pile, 20 tons. Since its erection not the slightest settling has been observed.

The chimney is of square section for a short distance from the base, and then takes an octagonal form to the top, ending in an ornamental cornice. The core is 14 feet in diameter. A feature of the design is an interior ladder extending from the base to the top of the chimney, to facilitate inspection.

THE POWER EQUIPMENT.

There was a time, not so very long ago, when in describing the power equipment of an electric central station a sharp line of demarkation could be drawn between the engines and the dynamos with the countershaft as the connecting link between them. That time is now past, and it stands to the credit of the Narragansett Company that it was among the pioneers in the adoption of direct connected units. Indeed, it was the first electric lighting company in the United States to install a direct driven alternator. This was, for the period, far more of an important innovation and new departure than it might appear to be now, even at so short a distance of time. It will be remembered that there was considerable talk and experiment on the subject in Europe, and the Narragansett Company looked across the Atlantic for their first machines of this character and size. American manufacturers were not, however, wanting in enterprise, and thus it came about that a radical change in practice was inaugurated that has been of immense benefit in central station operation.

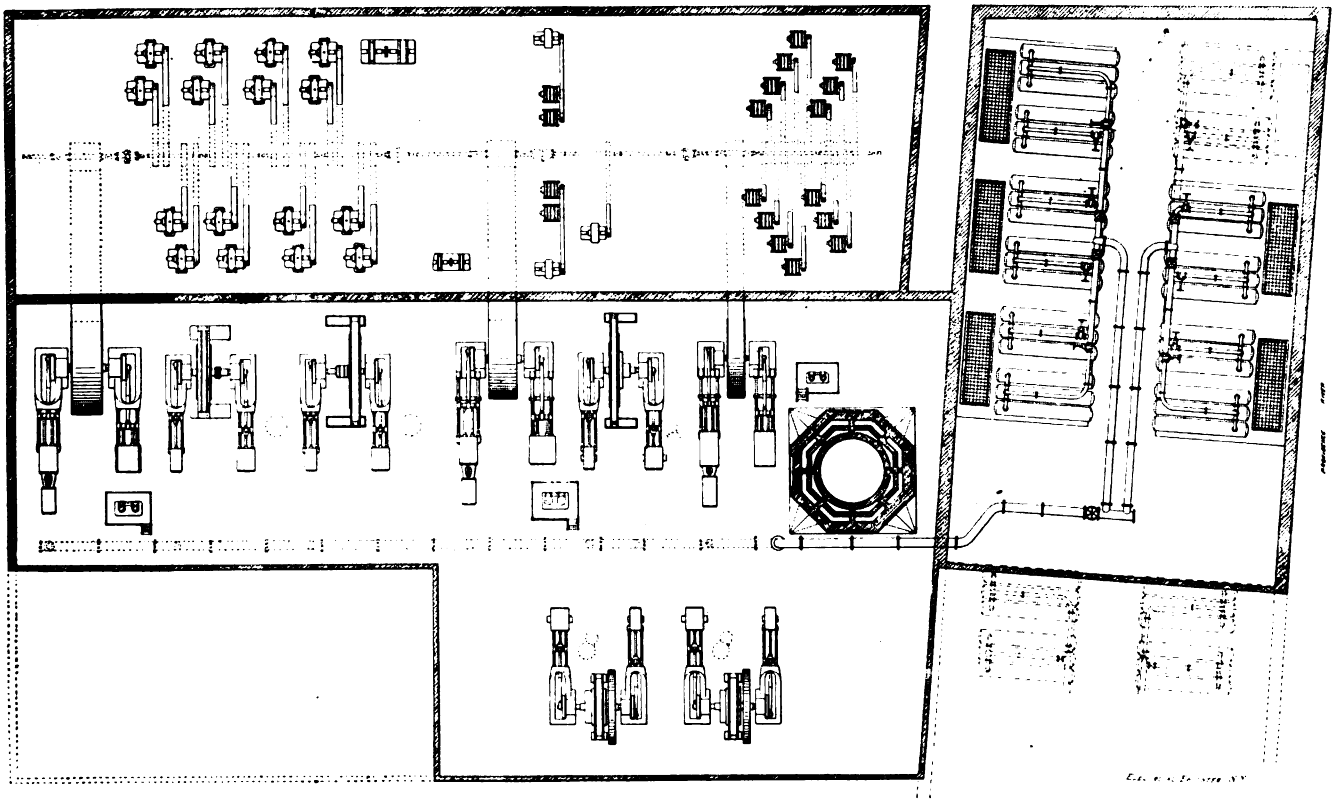
The foregoing remarks refer particularly to the direct connected units intended for constant potential service both alternating and continuous current. But as will be seen presently the countershaft is also met with in the Narragansett station for arc service—a remnant, as it were, of an ancient régime, but whose reign may be ended at any time. For the purpose of a better understanding of the nature of the power equipment, we may divide it conveniently into the three classes of service which it gives, namely: A 500-volt power service; alternating incandescent service, and arc lighting service.

The general arrangement of the engine room is shown on the plan on page 363. The present shape of this room is a notched rectangle whose greatest length is 200 feet, with a width of 102 feet, the notched unoccupied space of the lot being held in reserve for future additional equipment.

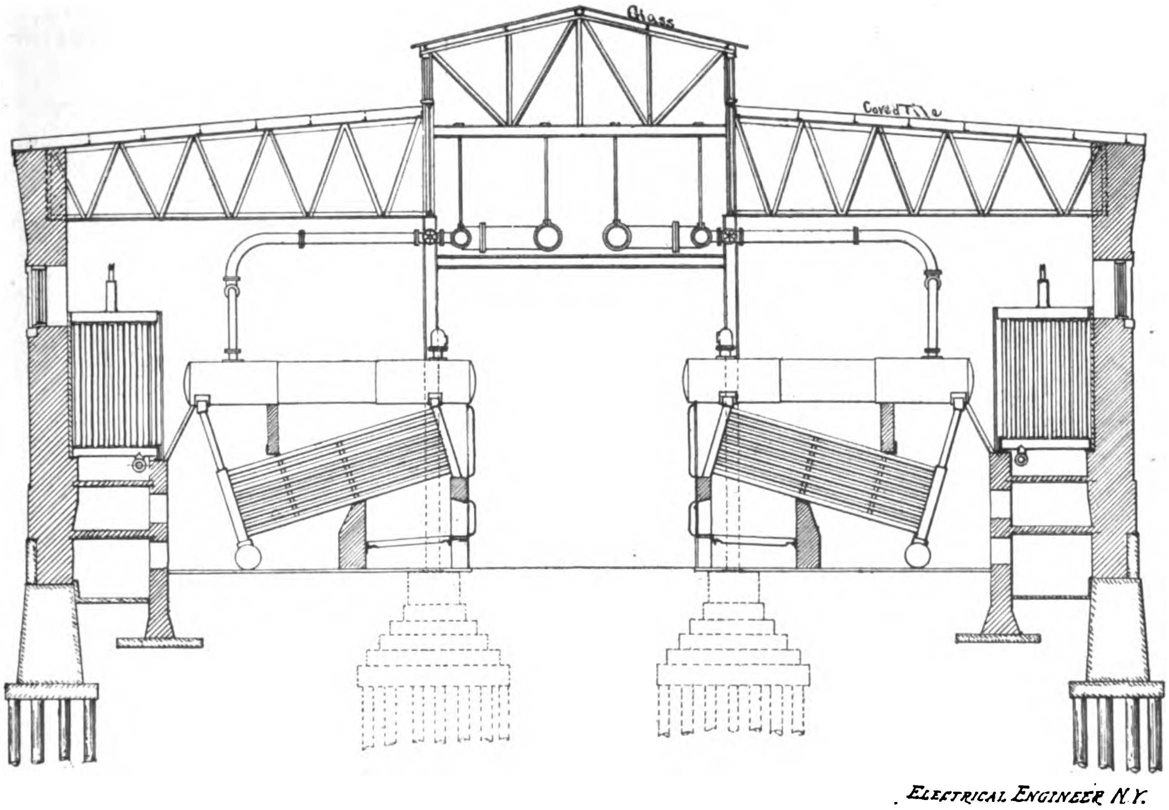
THE 500 VOLT POWER UNITS.

Looking from the boiler room to the left of the smoke stack will be seen two direct connected units, two views of which from opposite sides are given on page 365. The engines shown here are typical of all the engines in the station. They are of the 1890 Allis pattern of bed with wrought iron guides. This construction permits the engineer in charge to take in at one glance a whole row of engines, which he could not do with the usual style of box girder frame.

The engines are of the cross-compound Corliss type, all the cylinders being full steam jacketed and rather heavier than the standard pattern, with extra heavy journals. These, as well as the other cross-compound engines in the station, are fitted with direct connected air pumps. This pair of engines, built by the Corliss Steam Engine Company, of Providence, are directly connected to a pair of 500-kilowatt, 500-volt General Electric direct current generators. Each of these units is capable of supplying the present demand for power, one being kept as a reserve. The engines run at 90 revolutions per minute and so smooth has been their operation that in nearly two years no repairs of any kind have been found necessary, on either engine or generator, not even the commutator of the latter having been touched.



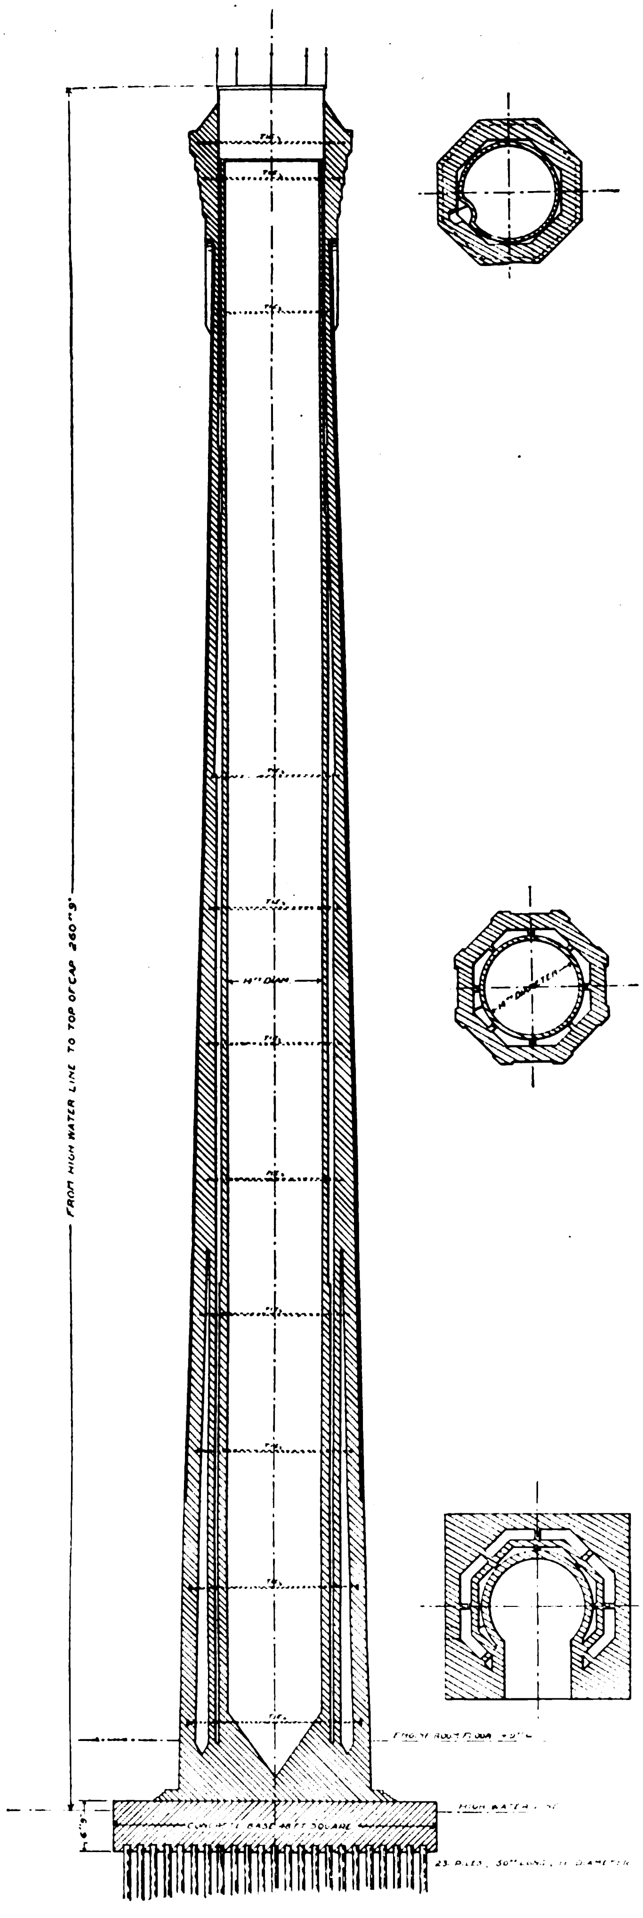
PLAN VIEW OF NARRAGANSETT ELECTRIC LIGHT STATION, SHOWING ENGINES, BOILERS AND DYNAMOS.



SECTIONAL VIEW OF BOILER ROOM, NARRAGANSETT ELECTRIC LIGHT STATION.

THE ALTERNATING INCANDESCENT UNITS.

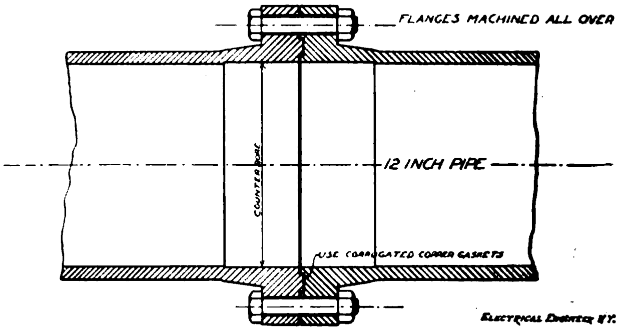
It was in reference to these that the previous remarks regarding the steps which led to the building of the first direct connected alternator in the United States applied.



FROM HIGH WATER LINE TO TOP OF CAP 260'-9"
6'-9"
HIGH WATER LINE
23 PILES, 30" LONG, 11" DIAMETER

SECTIONAL AND PLAN VIEWS OF SMOKE STACK.

The engraving on page 366 shows one of these pioneer units. It is of 400-kilowatt capacity with 80 poles and the armature revolving at 90 revolutions per minute, delivering current at 2,400 volts and 60 cycles, single phase, to the outside circuits. One of these alternators was built by the General Electric Co. Two other units of like capacity built by the Westinghouse Company complete the alternating current equipment. The exciters of these three machines are driven from their respective engine shafts.



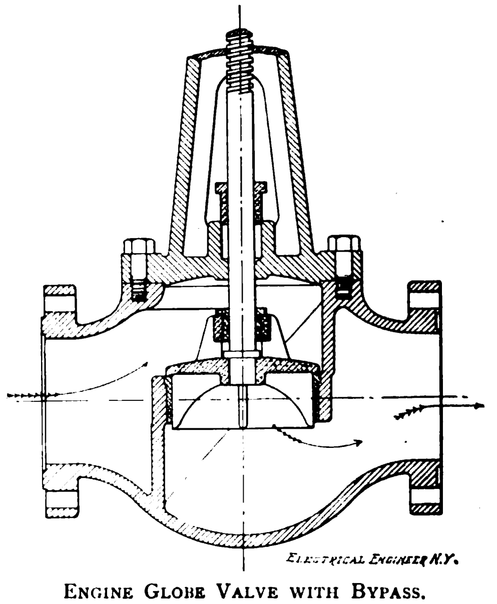
SECTION OF STEEL MAIN STEAM PIPING.

The engines driving the alternators are cross compound of 750 horse-power capacity each, and two were built by E. P. Allis & Co., the third engine unit being built by the Corliss Steam Engine Company. They conform in all essential particulars to the engines driving the 500-volt power generators described above. These three units are shown on the plan, page 363, forming a part of the line of engines running the entire length of the engine room. The total horse-power capacity of the station in steam units is 7,500.

THE ARC LIGHTING EQUIPMENT.

It is only when we come to the description of the arc lighting equipment that we are compelled to divorce the engines from the dynamos.

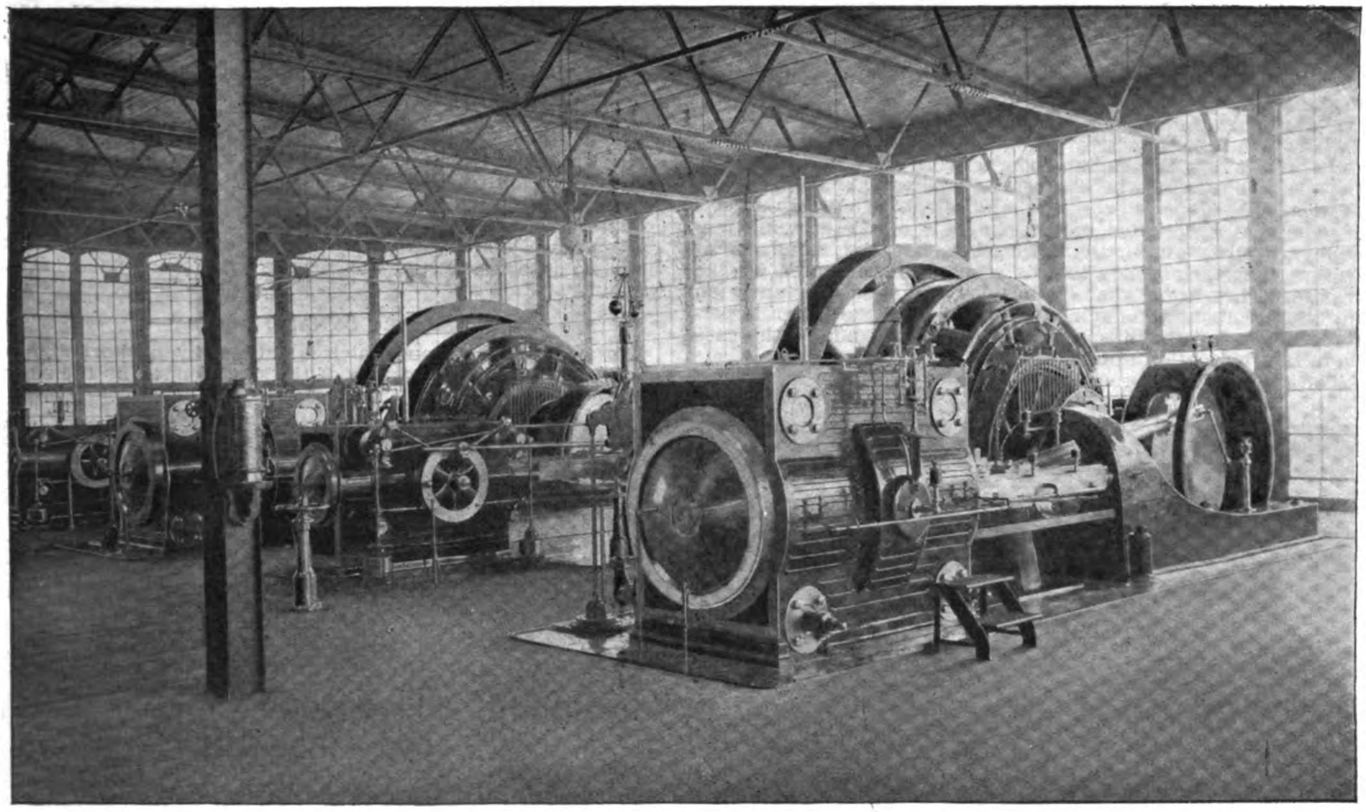
The nature of the load being a uniform one throughout the run, it was decided to install for this purpose triple expansion engines and, as a consequence, three of this type were erected, one of 750 horse power and two of 1,500 horse power each. These engines, built by E. P. Allis & Co., were the first triple expansion engines used for commercial purposes in this country, thus evincing once more the progressive policy of the company. These engines have independent air pumps and condensers of the G. F. Blake twin vertical type, and all the receivers are of the reheater type, steam at boiler pressure being circulated through wrought iron coils.



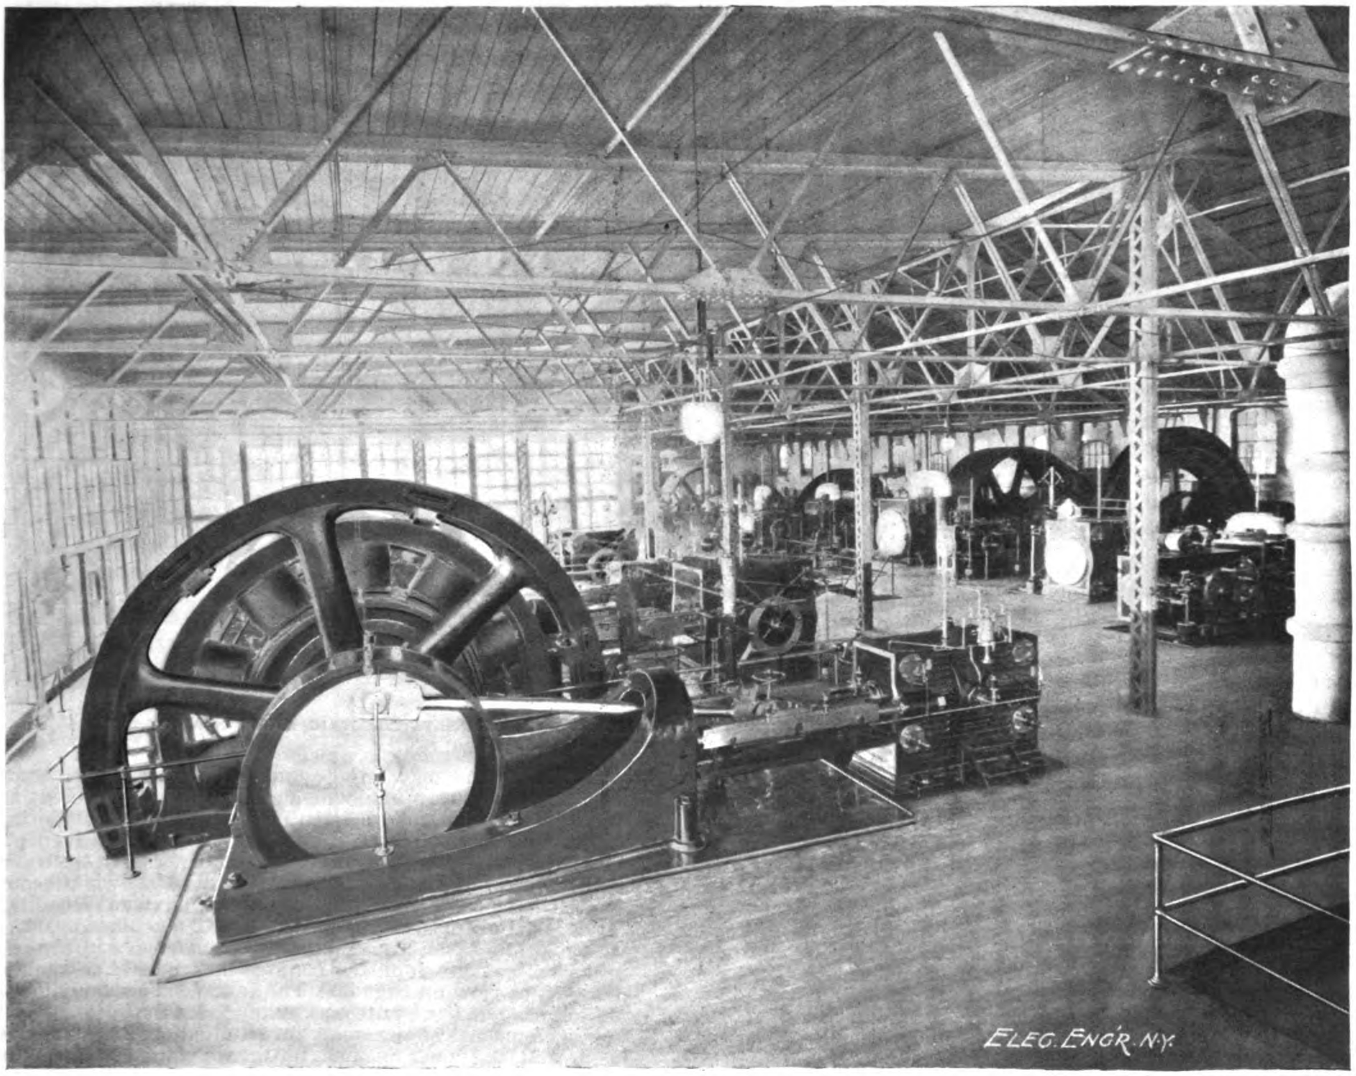
ENGINE GLOBE VALVE WITH BYPASS.

These three triple expansion engines used for arc lighting only, are belted to a countershaft running the entire length of the adjoining dynamo room, as shown in the sectional view on page 368. A view of the shaft alley is also given on page 367.

This main countershaft runs at 300 revolutions per minute. The shaft runs in ring oil bearings. No friction clutches are used, all clutches being positive. When it is desired to throw



500 Volt General Electric Power Units, Narragansett Electric Light Station.



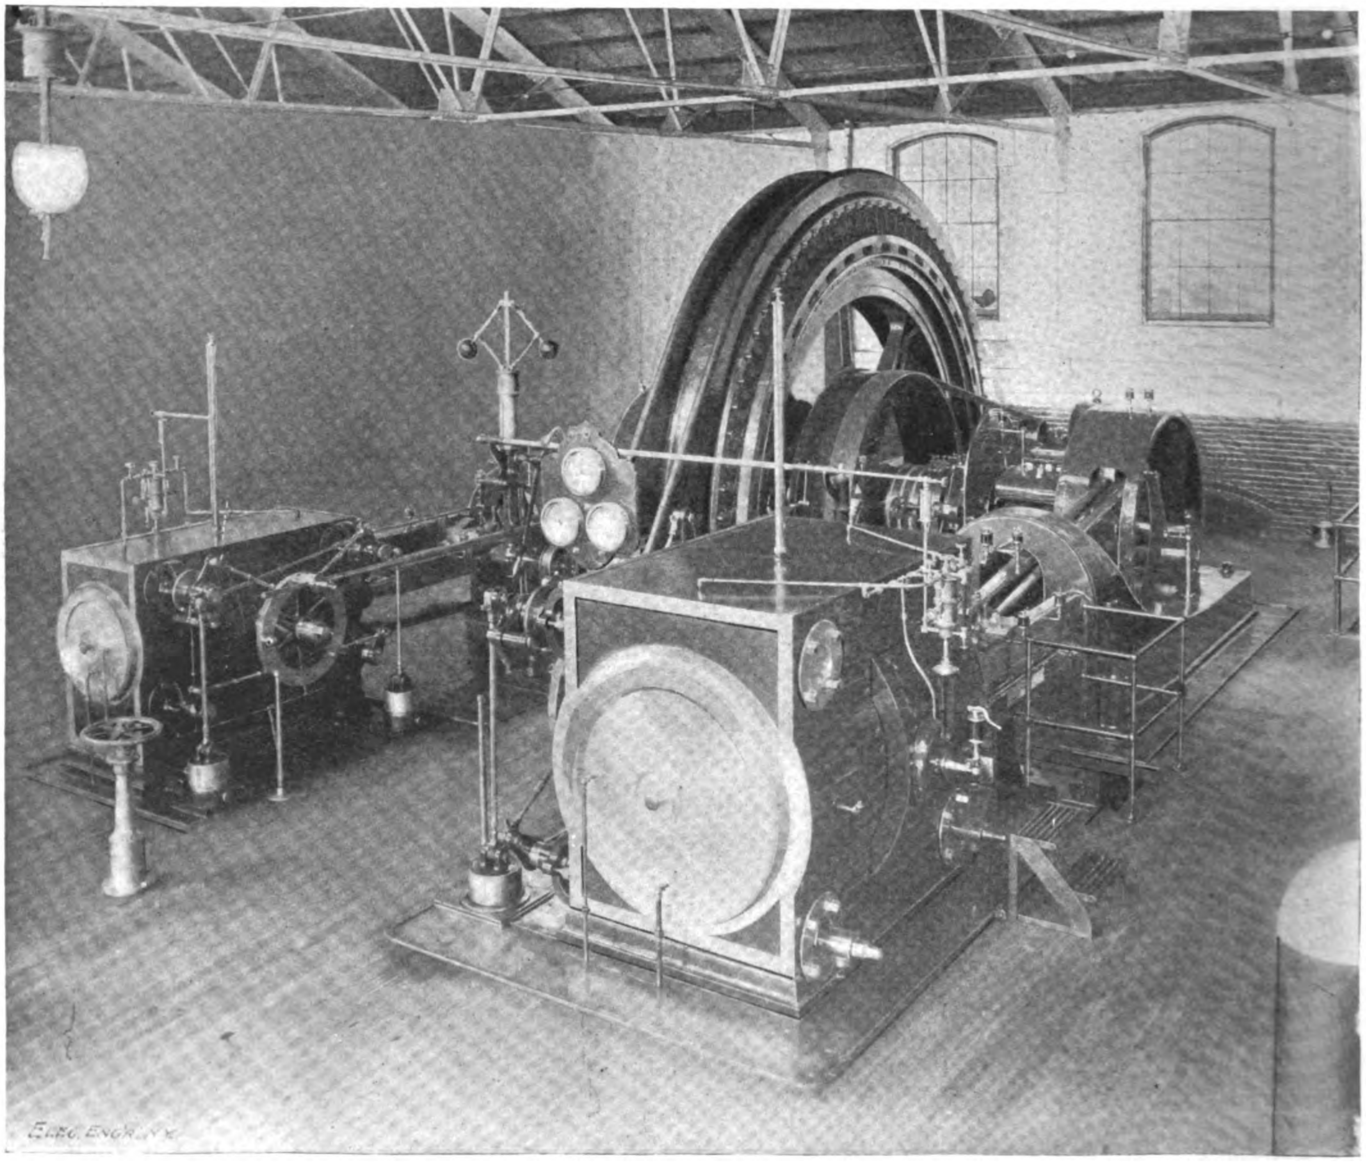
500 Volt General Electric Power Units, Narragansett Electric Light Station.

on additional machines, the engines are started up and coupled to the shaft when up to speed.

LUBRICATION, ETC.

Before leaving the engine room a word may be said about the general care of the engines and power apparatus. The lubrication is done entirely by hand oilers. This may appear a somewhat antiquated method in view of the growing tendency towards automatic lubrication, but the management believe that their policy in this respect is warranted by the results. They argue that by keeping the oiler constantly on his rounds about the engines, every part of the latter is perforce under constant inspection, which would not be the case were the lubrication automatic.

The lubricating oil required for the engine room is pumped up from below by a Holtzer-Cabot motor and Gould triplex pump to the oil stand, shown on the page opposite, and is thence distributed to the points required.



400 K. W. Direct Connected Westinghouse Alternator, Narragansett Electric Light Station.

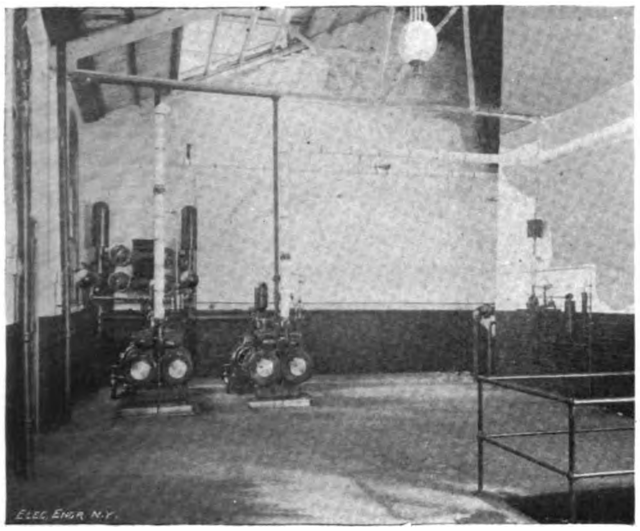
Much economy in oil consumption is effected by the use of a filter and purifier designed by the company's engineer and illustrated on the next page. The oil after use is led to the basement under the engine room floor into the large horizontal tank shown at the top, where it is heated by steam coils within the tank, and in which the heavy particles of foreign matter are precipitated. From this point the oil flows to the filters proper. Before entering the filter it passes through a body of water heated to 100 degs. and through a fine screen. The filtering material consists of wool waste and sponges. After passing through the filter, the oil drops through a pot of heated bone charcoal which clarifies it and at the same time evaporates all entrained water. The filter is cleaned periodically by simply pouring in hot water at the top and letting it run out at the bottom.

The belting employed at the station is furnished by the Page Belting Company, and Fayerweather & Ladew. The largest of the belts is 130 feet long and 6 feet 6 inches wide, three ply. It runs at a speed of 5,670 feet per minute, over a mile a minute. As indicating the efficacy of the methods adopted for engine and dynamo care, it is worthy of note that there has been no interruption of the service within a space of two years.

THE ARC DYNAMO ROOM.

The arc dynamo room which is entered by a short flight of steps from the engine room is of the same length as the engine room. Those who may have entered this part of the station less than three years ago will hardly recognize it now, such have been the changes in apparatus which it has undergone. Old types of arc machines of small capacity have given place to the more modern types and other changes have been made looking to economy of operation, as will be shown presently.

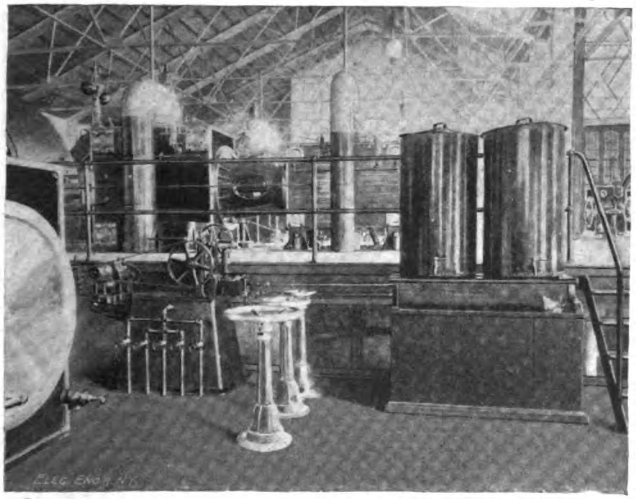
To the left of the entrance are situated sixteen Wood, Fort Wayne 125-light, 2,000-candle-power arc machines, each absorbing 65 kilowatts. These, like all the machines in the room, are driven by belts from the countershaft below, as shown in the sectional view on page 368. The new Wood arc machines are too well known to require any extended description. At the other extreme end of the room are situated eighteen Thomson-Houston MD_2 type ring armature arc machines. All these machines are employed for night lighting only. As it would evidently be poor economy to run the engines and counter shaft for the light day arc service, a special arrangement has been installed for this service exclusively. This consists of four Thomson-Houston arc machines driven two in tandem by two 500-volt General Electric M. P. 100 motors, which take their current from the 500-volt power generators in the engine room.



WORTHINGTON BOILER FEED PUMPS AND LOCKE DAMPER REGULATOR.

As stated, these arc machines carry the day arcs and the Sunday load, and also furnish current to the arc lamp testing and repair room. The economy of this method of operation must be obvious. A view of one of these pairs of motor-driven arc dynamos is shown on page 369.

Besides the arc machines there is a 100-kilowatt direct-current 500-volt generator driven from the main shaft which takes care of the commercial power service at night, a number of the Providence daily papers running their presses by electricity. This, it will be seen, allows the large 500-kilowatt generator units to be shut down completely at night.



OIL PUMP AND DISTRIBUTING STAND.

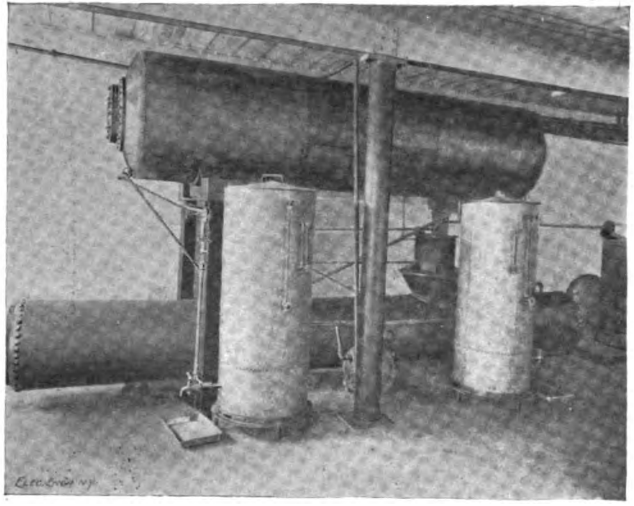
Tucked away at the side of the room finally is the small direct connected outfit shown on page 369. This consists of a 25-kilowatt G. E. induction motor direct connected to a 25-kilowatt direct current generator. The induction motor takes its current from the alternating circuits. This unit is intended to furnish current for testing wattmeters, and also for commercial purposes, when the power load is very light, as on Sundays and holidays. A similar outfit of 100 kilowatt capacity will shortly be installed, so that under no circumstances need the 500-kilowatt direct-current generators run under light load.

It will be noted that no wires leading to any of the machines are visible in the view, given on page 368. All wiring is, in fact, run below the floor on vertical racks, the conductors being supported on porcelain insulators mounted on slate.

THE SWITCHBOARDS.

The three classes of service, power, incandescent and arc lighting, are controlled by individual switchboards, ranged side by side at the end of the room facing the Fort Wayne arc machines. These are shown in perspective on page 369.

The board at the extreme left, ranged at right angles to the other two, controls the power circuits. It is of the simple, multiple type and provision is made for eight feeders and four generators. Weston ammeters are placed on each feeder and generator panel, and Weston differential voltmeter and potential indicators are plugged in on a tablet board shown in front of the switchboard. In fact, all the indicating instruments on all the switchboards are of the Weston type.

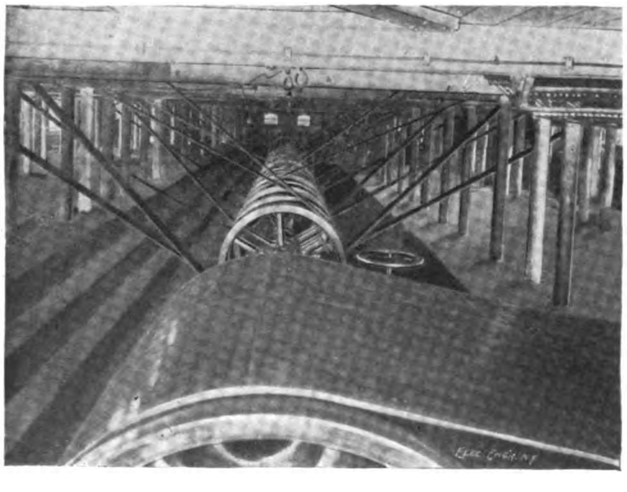


OIL FILTER AND PURIFIER.

The arc switchboard occupies the position at the extreme right hand. It consists of seven panels with provision for six circuits and six dynamos to each panel. The panel slabs, of white marble, are boiled in paraffine. All contacts are on the back of the board, which is of the plug type and was manufactured by the Allen Fire Department Supply Company, of Providence. It is noteworthy that this board was the first of its kind built in this country for service in connection with high tension (7,000 volts) arc work. Besides the usual ammeters and voltmeters, the board is provided with a voltmeter ground test showing the approximate location of a ground.

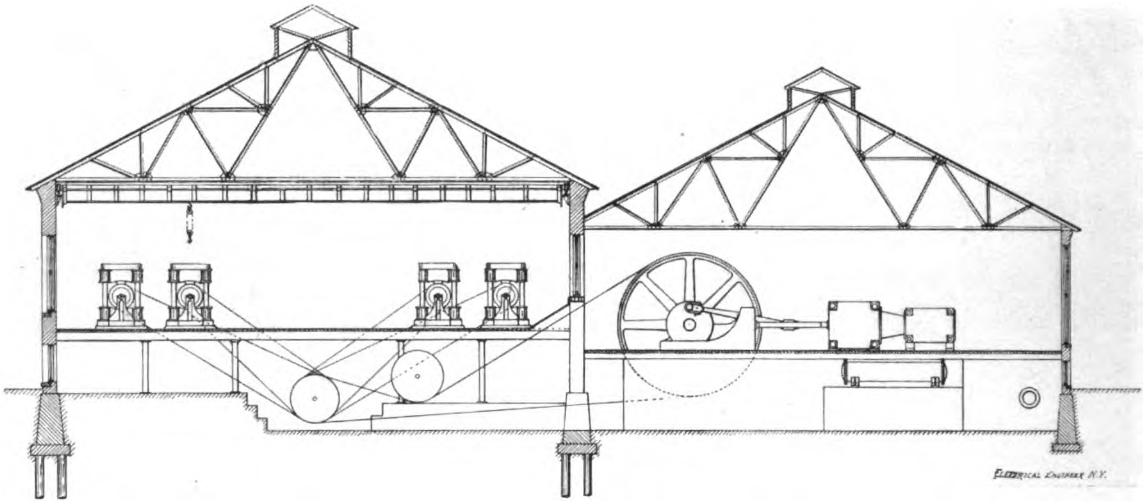
The alternating incandescent switchboard which stands between the two boards just described will soon be replaced by a new one and as the latter embodies the latest improvements in the art we believe our readers will prefer to have it described rather than the old one about to be discarded.

The new alternating switchboard now being built by the Stanley Electric Manufacturing Company, will be of white marble to harmonize with the adjacent boards, and the illustration on page 370 shows one panel of the board in front and side view. The board will stand 66¼ inches high with an



THE SHAFT ALLEY UNDER ARC DYNAMO ROOM.

overall length of 26 feet and 4 inches; this length containing four generator panels and ten circuit panels supported 6¼ inches from the floor upon 15 iron pipes 2½ inches in diameter. The ordinary pipe flanges are used for fastening to the floor and are covered with a neat polished brass shield, while each upright is provided with iron brackets to which the marble is bolted. Polished caps surmount each pipe from which hang goose necks with sockets and lamps for lighting the board and for use as pilot lamps.



SECTIONAL VIEW OF ENGINE AND ARC DYNAMO ROOM, NARRAGANSETT ELECTRIC LIGHT STATION.

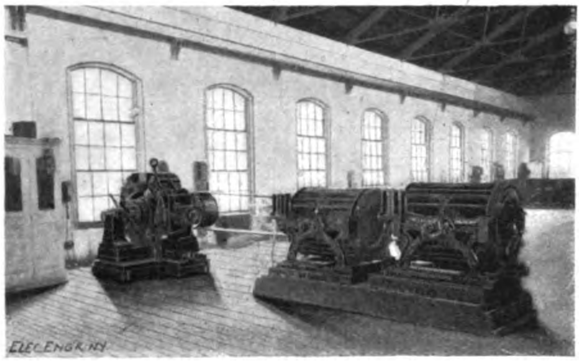
To guard against the attendant coming in contact with live metal (2,400 volts alternating are employed), all switches are placed at the back of the board and operated by thoroughly insulated handles at the front. The main switches used are two pole, single-throw, and have a capacity of 200 amperes, being so arranged as to cause a simultaneous break at four points of the circuit. Each of these four breaks is provided with an "enclosing box" or arc rupturing device, making an absolutely safe switch for handling these large units. The circuit switches, page 370, are similar in design to the main generator switches, but are double-pole, double-throw. In connection with the plugs and cables this arrangement enables the attendant to transfer any circuit upon any set of bus bars corresponding to any generator. The plugs and plug receptacles used are of a new design which makes it practically impossible for one to cause a wrong connection or to come in contact with any line terminals; the plugs are also provided with special, high insulation cables, insuring absolute safety. Perfect contact between plugs and receptacles is gained by corresponding tapering surfaces (the plug having a taper hole and the receptacle a cone-shaped projection) which are ground to a perfect fit. These surfaces are drawn tightly together by a locking device which also prevents jarring off by constant vibrations or other causes. The metal parts of the receptacles are back of the board and the corresponding hole through the marble is covered with a molded rubber cap.

THE ARC DYNAMO ROOM, NARRAGANSETT ELECTRIC LIGHT STATION.

The rheostats placed at the bottom of the four generator panels are of the wire-wound type for the back of the board and each is in circuit with the field of one of the exciters. At the back of the board and in connection with the field switch is a resistance for taking up the "kick" when the field circuit of an exciter is opened. The ammeters are provided with nickel covers and are of sufficient capacity for the several generators and circuits.

Static ground detectors of the Stanley make are provided for each generator or corresponding set of bus bars; a full description of these instruments will be found in The Electrical Engineer of February 17, 1897. Each generator and circuit is also provided with a static voltmeter similar in principle to the ground detector, those on the circuits being connected to pressure wires from the centers of distribution.

Supported from the back of the iron pipe framing is an insulated bracket for the bus bars, the arrangement being clearly shown on next page. The bus bars are of solid round copper one inch in diameter and are provided with special bus bar connectors for making connections to the main switches and the plug receptacles of the circuit panels; the arrangement of this and of the entire board is such as to permit of the addition of generator or circuit panels at any time. The marble used is clear white Vermont marble and in this case was all boiled in hot paraffine to improve its insulating qualities.

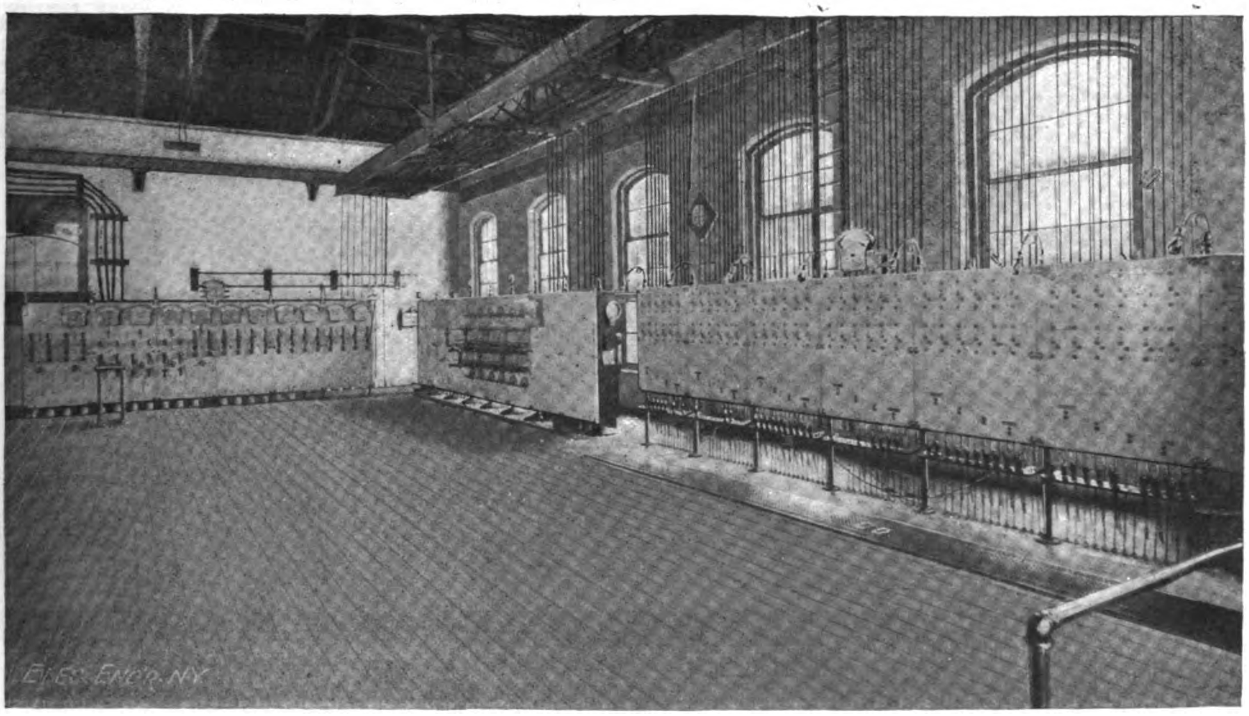


Motor Driven Arc Machines for Carrying Day Load.

Each circuit will be provided with a Holtzer-Cabot automatic regulator, connected to pressure wires from the centers of distribution.

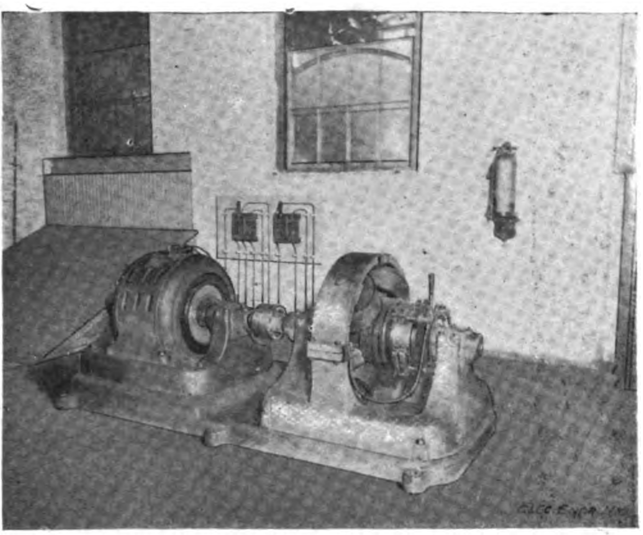
The booster regulator is a combination of the General Electric M. R. type, having a capacity of six kilowatts, and the hot wire, automatic regulator of the Holtzer-Cabot Electric Co.

In the booster regulator, shown on page 370, the variation in voltage is accomplished by moving a laminated iron core within the shunt and series windings of the alternate current main circuit, the increased or diminished voltage depending on the mutual induction of the windings, which induction changes continuously with a movement of the core. The core is driven by a shaft which is coupled by means of a worm gear to an iron-clad Holtzer-Cabot motor, in which the direction of rotation depends on the tendency of the voltage of the external circuit to increase or diminish. The motor is driven by a storage battery having a maximum potential of 230 volts and it has a constant speed of 2,000 revolutions.



The Arc, Incandescent and Power Switchboards, Narragansett Electric Light Station.

The operation of the system is as follows: If the voltage on the alternate current mains at the center of distribution on any one set of feeders increases, the hot wire indicator of the Holtzer-Cabot regulator, through the medium of the pressure wire, makes a contact that starts the motor, which in turn rotates the laminated core of the booster to such a position that the e. m. f. of the set of feeders controlled by that booster is brought to a normal point. When that point is reached the hot wire indicator is in contact with neither side and the motor is at rest. If the voltage at the center of distribution should decrease, the operation would be the inverse of that outlined.



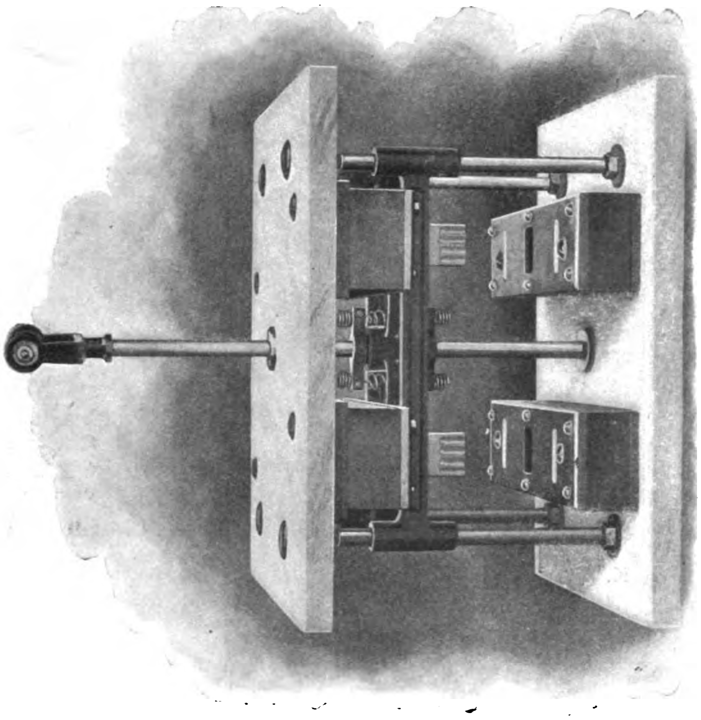
25 K. W. Combination Unit Induction Motor and 500 Volt Direct Current Generator.

This board will also be provided with Bristol recording voltmeters, giving a continuous record of the pressure at the ends of the feeders.

TESTING AND INSPECTION DEPARTMENTS.

The high standard of service maintained by the management of the company makes it necessary to provide means for the testing and inspection of all supplies furnished. This work is carried out in a building adjoining the station.

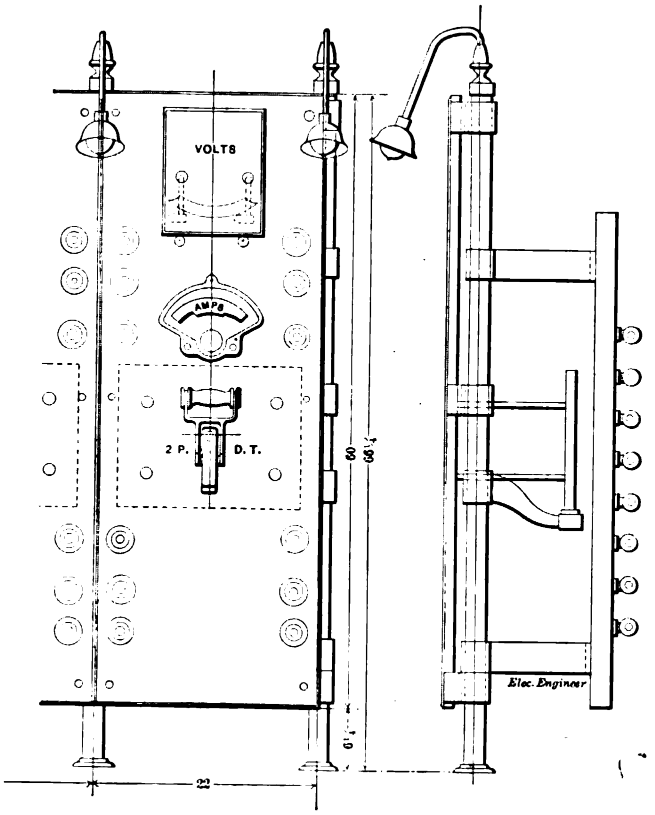
Situated on the ground floor is the meter testing room. Here the Thomson wattmeters employed on the power circuits and the Shallenberger meters on the lighting circuits are given a rigid time test before being sent out, the load being taken by Carpenter enamel rheostats made by the Ward Leonard Company. The meter testing room is illustrated on opposite page.



Stanley Co.'s 2-Pole D. T. Slide Switch—Out.

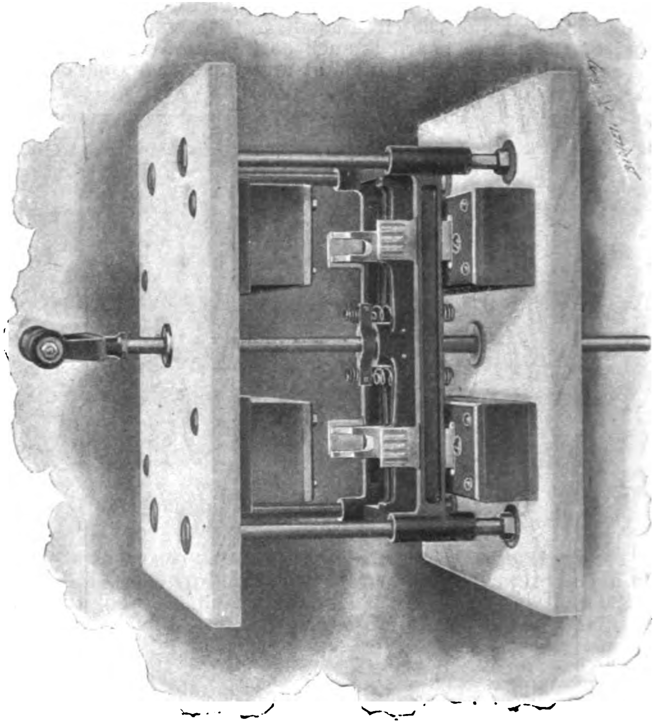
The incandescent lamps are tested in the room also shown on that page.

Every incandescent lamp bought by the company is tested for candle power and efficiency, and those not coming within the required limits are rejected. At stated intervals life tests are made.



The New Stanley Alternating Current Switchboard.

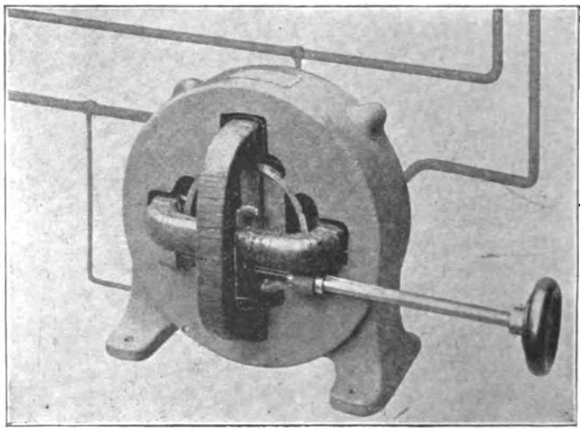
The photometer room is provided with the latest type of Lummer-Brodhun photometer and Methven screen. The Weston laboratory standard volt and ammeters are employed here, and indeed each department is equipped with Weston or General Electric instruments, which are regularly calibrated by standards. In fact, no expense has been spared to improve the efficiency of the service by the introduction of reliable high-grade instruments.



Stanley Co.'s 2-Pole D. T. Slide Switch—In.

The arc lamps employed by the company are of the T-H, M, type. These are tested in the room illustrated on opposite page, which also constitutes the repair shop, being provided with all tools necessary for the purpose. The shop is ventilated by an exhaust fan, which removes the noxious gases and the heated air, which rapidly accumulate in rooms devoted to arc lamp testing purposes. Here also the carbons are tested. At present the company is using the Crouse-Tremaine cored carbons on their commercial arcs and solid copper coated carbons on the city lights.

The building containing the testing and inspection departments also contains the offices of the mechanical and electrical engineers, as well as a store room for supplies of various kinds.



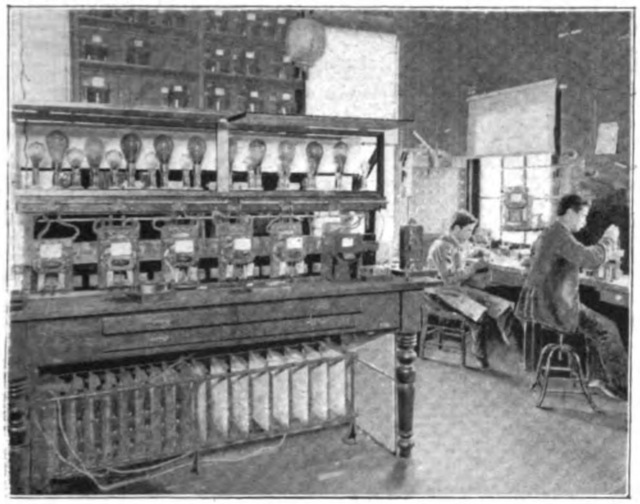
Feeder Potential Regulator.

LINE CONSTRUCTION AND OUTSIDE WORK.

The circuits as they leave the switchboard are taken directly up into the wire tower overhead, an outside view of which is shown on page 361. From this tower emanate 16 arc circuits of 125 lamps each; 15 arc circuits of about 50 lamps each; 6 sets of feed wires for power service, and 10 sets of feed wires for alternating services. The tower is readily accessible both inside and outside, so that every foot of wire is within reach.

The floors in the tower are of slate, laid on felt, so as to give absolute protection.

The distribution throughout the city for all classes of service is on pole lines. For this purpose poles of hard Southern pine are used, varying, according to the number of circuits to be carried, from 16 x 16 inch square to 10 x 10 inch square, chamfered and painted green. They vary in height from 35 to 65 feet. The cross arms are of the same wood as the poles.



THE METER TESTING ROOM.

No wooden insulator pins whatever are used. In their stead there are employed malleable iron pins, screw threaded at both ends. One end screws into the cross arm and the other receives the insulator.

The line wires are of the 3-braid weather-proof type, made by the American Electrical Works; the motor and alternating taps are rubber covered, Okonite; and Okonite cable is used for crossing the river.

Each pole line is surmounted by three guard wires, one 12 inches above the top of the pole and the other two at the extreme ends of the top cross arm and supported by 12-inch irons at those points. Thus protected, foreign wires may fall upon, but cannot effect crosses with the company's live wires.

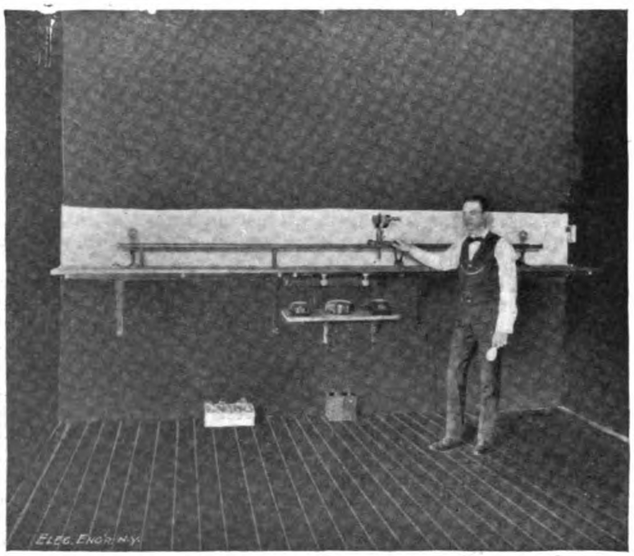
PROPOSED SYSTEM OF STORAGE BATTERY SUB-STATION DISTRIBUTION.

The street arc lamps are supported on Russell mast arms. These have rigid hollow arms, with a trolley running inside. The lamp is pulled in when trimmed. All the lamp trimmers are provided with bicycles which are their own property, and the street circuits are regularly patrolled at frequent intervals by seven patrolmen. The result of this constant supervision is that during the past year the lamp outage on the city lights was less than 1-7 of one per cent., a record which, it may well be claimed, is the best as far as known. It is probable that the cost of patrolling the lines is greater than would be the rebates exacted by the city for outages, under the ordinary conditions, but the company's policy has always been to afford the best possible service.



Elec. Eng'r N.Y.
THE PHOTOMETER ROOM.

DISTRIBUTION DATA.

As stated above, the alternating current is distributed at 2,000 volts and reduced by transformers to 50 or 100 volt secondary lines. There is also a 5,000-volt service with step-up and step-down transformers which feeds the Warwick district, the extreme end of which is 14 miles from the central station.

At the present time there are connected to the motor circuits 395 motors, aggregating 2,500 horse power, at 500 volts, not including the motors in the station. This, it is believed, is the largest 500-volt motor service in the country. These motors supply power to almost all the many industries carried on in Providence, including numerous elevators and newspaper printing presses. Electric motors connected to the circuits also drive the calling generators at the Providence telephone exchange. Recently also the Western Union office has been equipped with a duplicate set of motors which drive generators that furnish current for all the principal trunk wires, Associated Press and railroad wires out of Providence. It is also interesting to note that the new bridge draw over the Seekonk River is operated by motors and the bridge itself lighted by the 500-volt current.

There are 2,800 arc lamps in circuit, of which 2,000 are street lamps, and 800 commercial lamps. All of these are of 2,000 candle power.

There are 47,000 incandescent lamps connected to the alternating circuits.

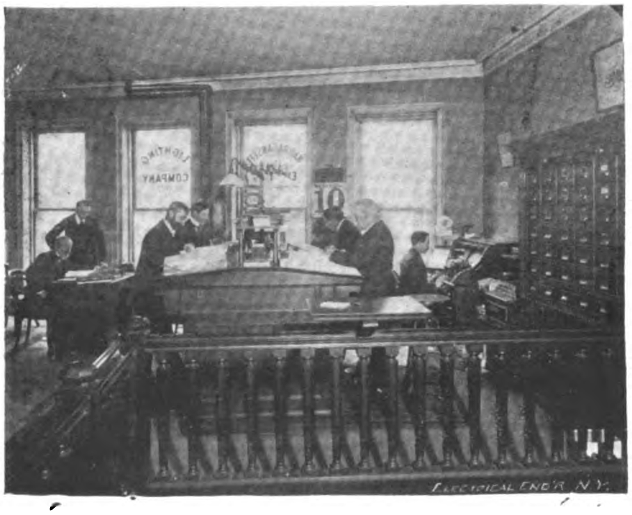
FUTURE DEVELOPMENT WITH STORAGE BATTERIES.

The progressive management of a central station to-day has but a small possible margin to gain in efficiency of apparatus, and the betterments of the system are mainly possible in the improvement of the service rendered the consumer and in the increased efficiency of the incandescent lamp, at the same time maintaining the present effective standard of life, say on an average 600 hours.

Fully recognizing the high standards that will be demanded in the immediate future for absolutely uniform regulation for incandescent lighting, for a service that shall be economical and almost exempt from possibility of interruption, and anticipating that the perfected storage battery and the high voltage incandescent lamp will soon play an important part in central station operations, Mr. Marsden J. Perry, the vice-president and general manager of the company, has suggested a plan of substation supply by means of the storage battery, the charging circuit being the present 500-volt power current, the battery to discharge at lamp voltage and independent of the charging circuit.

Briefly stated the arrangement is: A central station of 4,400 kilowatt capacity now operated as a composite outfit, that is, series arc service, alternating, single phase, incandescent lighting, and direct current 500-volt motor service. The motor service at present represents an installation of 2,500 horse power in stationary motors; the arc service, 2,800 lamps, and the incandescent service 47,000 lamps.

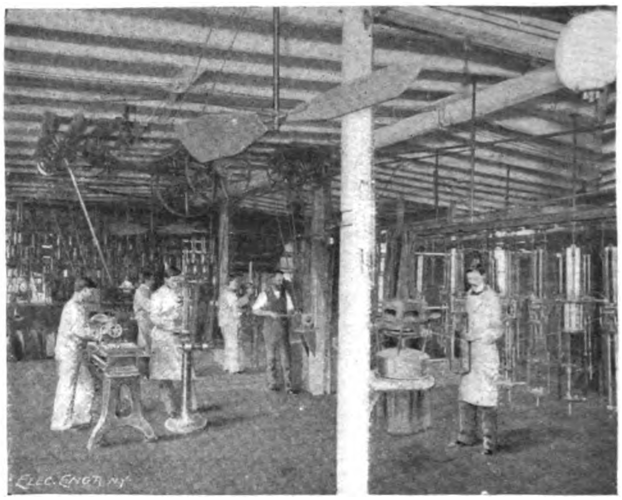
In the load curve diagram of the Narragansett station at the present time the peak of the curve practically offsets the gap in it. It is proposed, therefore, to charge the battery substations during the light load period, making the storage battery virtually a motor load after 12 o'clock at night and substantially an additional motor load during the day, and thus practically operate the station at a nearly constant load throughout the 24 hours. The novelty in the proposed arrangement lies principally in the fact that the batteries are charged in series or groups from the 500-volt power service, and, when discharging, are switched over to low tension mains, as indicated in the diagram on page 371. This arrangement, of course necessitates two groups of batteries whose combined capacity is sufficient to supply the watt hour load of the system during the hours covered by the peak.



ELECTRICAL ENG'R. N.Y.

A VIEW IN THE MAIN OFFICE.

At first it is proposed to equip only one section of the city, but the developed idea would eventually include all commercial arc and incandescent lights within a two-mile radius of the station, the remaining outlying territory to be supplied as at present. The territory embraced is so arranged that four, or possibly five, substations would be required, the several stations being connected so that, in the event of interruption at any one station, the load of that station would be assumed by the others. This arrangement would also permit of the night load or light day load being operated from one point. The details of the system are yet to be worked out. Although storage substations charged in series from high tension circuits have long been before the public, yet this is possibly the first instance of substations operated when the charging circuit is 500 volts and treated simply as a big motor on the power lines.



ELEC. ENG'R. N.Y.

THE REPAIR SHOP.

Comparing this method of substation supply with that already in vogue, it may readily be seen that its chief merit lies in obviating the fluctuations always noticeable in composite circuits, that is, circuits furnishing current for incandescent lighting and motors, especially as motor loads are subject to a wide range of variation, such as stopping and starting elevators, driving circular saws, etc. The regulation may be made absolute by the introduction of a device which will automatically maintain a constant pressure at distributing points on the consumers' circuits. Such devices are already in absolutely successful operation at the storage battery station of the Edison Electric Illuminating Company, of Boston, and also on the alternating lighting service of the People's Edison Illuminating and Power Company, at River Point, R. I.

A second point in its favor is a commercial one. A large field for motors, many of the latter on the outskirts of the city and a long distance from the central station, may be reached with much less copper than would be required with the low potential at which the storage batteries are ordinarily charged and discharged, and a large amount of power business could be secured with this proposed high voltage charging current that the cost of copper at low potential would make absolutely prohibitive. Thus the public could be accommodated and the volume of business for the station be handsomely increased.

From 11 to 12 o'clock p. m., most of the commercial arcs or store lights are extinguished, the volume of the incandescent output is largely reduced, and from that time until the next morning the storage battery takes the place of these two factors and keeps the station load nearly uniform. In the morning the city arcs are discontinued, but the motor service begins and the charging of the storage battery takes the place of the city arcs and thus continues to act as a load equalizer until the afternoon, when the commercial arcs and incandescent load are resumed. The charging of the storage battery may then be discontinued during the peak hours. Thus maintaining a nearly uniform load for the whole 24 hours will enable the generating station to be operated at the highest possible point of economy and efficiency.

LITERATURE

STANDARD WIRING FOR ELECTRIC LIGHT AND POWER.—By H. C. Cushing, Jr. 93 pages. Pocket size. Flexible Leather cover. Price, $1.

Several new and valuable tables have been added to this work which will make it particularly welcome to central station managers and engineers throughout the country. This is the fifth edition, and, like all the previous editions, is gotten out in a soft leather cover and of convenient size for the pocket. We believe that the work is having a good influence everywhere towards standardizing electric light and power installation from a fire underwriter's standpoint.

TELEPHONY AND TELEGRAPHY

ANNUAL FIGURES OF AMERICAN BELL TELEPHONE OPERATIONS.

THE stockholders of the Bell Telephone Company held their annual meeting at Boston on March 30. One action taken was the substitution of T. Jefferson Coolidge, Jr., on the board of directors in place of Charles P. Bowditch. The other was the 10 per cent. increase in the capital stock of the company, or an increase of $2,365,000 to $26,015,000, making the total number of shares outstanding 260,150, of a par value of $100.

Treasurer William R. Driver and Clerk Charles Eustis Hubbard were re-elected. The following board of directors was also elected by a unanimous vote: Charles W. Amory, Francis Blake, George L. Bradley, Alex Cochrane, T. Jefferson Coolidge, Jr., William H. Forbes, Henry S. Howe, Charles Eustis Hubbard, Gardiner G. Hubbard, John E. Hudson, Charles E. Perkins, Thomas Sanders, Moses Williams.

President John E. Hudson, who presided, read the annual report of the company. In his opening remarks he said: "The adoption by many more of the exchanges throughout the country of the measured service and party line system, under which the service can be furnished at a lower yearly rate, has contributed materially to the gain in subscribers."

President Hudson also spoke of the growth of the telephone from year to year, and of the privilege of subscribers now to talk to almost any part of the country. He said that the increase in the number of long distance calls reflects the appreciation by the public of the value of the telephone.

The 32 subsidiary companies operating under license from the Bell company expended $8,271,929 for new construction and $1,160,924 for real estate.

In conclusion he touched upon the suit of the Berliner patent, which is still in abeyance, and expressed a wish for its speedy settlement.

"The Long Distance company has invested up to Dec. 31, 1896, in land, construction, franchises, equipment and supplies, $13,187,299. That company shows an increase in gross earnings in 1896 over 1895 of 20.6 per cent., the 1896 gross being $1,599,589. It will be remembered that the gross earnings for 1895 were $1,326,683, for 1894 $1,101,961, for 1893, $892,361, and for 1892 $643,436."

The statistical portion of the report for the fiscal year ended Dec. 31, 1896, makes the following comparisons:

EARNINGS.	1896.	1895.
Rental of telephones	*$2,458,484	$2,125,359
Dividends	2,616,307	2,523,150

*Increase.

†Includes dividend payable Jan. 15.

TELEPHONY AT HARMONY, MINN.

An ingenious and enterprising scheme will be put in operation in Fillmore County, in the shape of a mutual telephone company, with headquarters at St. Paul, Minn. The company has already been organized, with D. E. Horton as president; H. Bellingham, treasurer, and H. J. Achatz, as secretary. The company will commence building as soon as the frost is out of the ground. The farmers take readily to the plan, as it will put them in daily communication with the markets and shippers. The fee for joining is $10, which is applied on construction and each pays for his own instrument. It will be run without cost to subscribers, except small assessments for repairs as they become necessary. There will probably be an exchange established in Harmony.

COULDN'T BEAT ELECTRICITY.

Policemen and watchmen had a running fight with a negro burglar on the levee at Chicago at an early hour on March 18. The fugitive inadvertently sent in an alarm and was surprised at work by Captain King of the patrol. At 3 o'clock a. m. an alarm was received by the patrol from the store occupied by Heyman Bros., tailors, at 380 State street. Captain King hurried to the rear of the store and as he climbed over a shed from the alley saw a colored man at work trying to cut through the iron bars which cover the rear windows. The robber ran. King fired. The robber returned the fire. Officers Kerwin, Vernoven and Reick joined in the fusillade, and a sensational running fight ended with the capture of the thief, who gave his name as William Brown. The window at which he was at work was protected with an alarm system which, when cut, opened a circuit and sent in a warning.

AN ELECTRICAL EXHIBITION is to be held at Como, Italy, in 1899, to celebrate the centenary of the Volta pile. Turin is to have a similar exhibition in 1898. The great trouble is, we don't have electrical exhibitions enough.

THE
ELECTRICAL ENGINEER
[INCORPORATED.]

VOL. XXIII. NEW YORK, APRIL 7, 1897. No. 466.

Notice of Removal.

THE ELECTRICAL ENGINEER

on and after April 14 will occupy its handsome and commodious new suite of offices, entire south wing, eleventh floor, of the Beard Building, 120 Liberty street, New York City. It will not only thus be most advantageously situated at the heart of the machinery and electrical district, but will enjoy an increase of several hundred feet floor space. The offices are convenient to all railroads and ferries, and an invitation to visit them is cordially extended to all friends and patrons of the journal.

A MODERN COMPOSITE PLANT.

TEN years ago a visitor entering what at that time would have been called, and justly so, a model incandescent lighting plant, no matter what its size, would have beheld a row of high speed engines probably not exceeding in capacity 250 horse power each, belted to a like number of generators. This method of driving was an advance on the older system involving the use of countershafting and was made possible by the perfection reached in the building of high speed engines. But with increasing demands for generator units of large capacity for both arc and incandescent lighting, railway and power purposes, came the direct connected unit and its success, in turn, has reacted upon the smaller units so that even for these the direct connection has become a favorite method. But how many of the model stations of ten years ago can be rightly so designated at the present time. It takes courage, even where the means are available to carry out the work, to discard apparatus which is operating satisfactorily, and comparatively few companies have screwed their courage to the necessary sticking point. Among those few a most conspicuous example is presented in the Narragansett Electric Lighting Company, of Providence, R. I., whose magnificent station is described in detail in this issue. The enterprising manager of this company, Mr. Marsden J. Perry, from the very beginning, started out with the fixed purpose of maintaining the station under his charge at all times up-to-date and though that determination has necessitated several remodellings within the past ten or twelve years, the results both in the character of the service rendered, and from the financial standpoint have fully warranted the expenditures involved. But after all, the expense in keeping up to date, depends largely on the manner in which the process is carried out. If the old apparatus was bought ten years or more ago, its value will probably be little greater than that of scrap, but electrical apparatus and engines that have been well taken care of, after a period of three or five years would in but very few instances be entirely out of date and would consequently still possess a fair percentage of their original value, which would reduce materially the cost involved in the change. In these days of constantly decreasing prices for electric service the station that is struggling along with old apparatus ill adapted to the changed conditions of service demanded, and what is worse, of low efficiency, cannot hope to maintain the contest against the new and efficient apparatus now available. Those companies which have in the past made provision for the inevitable change, or those which have increased their capital to meet it will survive and be the better for the change, but the future is indeed dark for their less fortunate brethren who have neither of these resources to fall back on. And this constant necessity of keeping up to date is, it seems to us, one of the essential points, which those who advocate municipal ownership of electric lighting plants, as a rule, fail to take into account. The day will inevitably come when the present municipal plants must either be changed over to conform to the latest and most economical systems of current generation and distribution, or will be forced to that change by the natural wear to which all machinery is subject. This applies as well to the boilers and engines as to the electrical machinery. When that time comes,, as it must, and additional city bonds have to be issued to meet the expense, we may expect to note a sudden revulsion of feeling on the subject and a sudden desire to sell the municipal plant to some corporation which will undertake the necessary expense, and put the city in a position to know exactly what its lighting is costing it.

SPECIAL LIGHTING FOR BUSINESS STREETS.

HOW to make a given part of the business section of a city attractive, is a problem that merchants often have to deal with. Clean streets by day and bright streets by night are a help. At Columbus, O., in a part of the city that is a trifle tame during the evening, the merchants conceived the idea of resorting to the electric light in order to induce an increase of shopping trade. They put a series of arches therefore over a 50-foot roadway, from curb to curb, the arches being about 250 feet apart. Each arch contains 50 incandescent lamps of 16 candle power each. It is hard to tell whether they have or have not accomplished their purpose, but as the merchants at the other and busier end of the street now contemplate doing the same thing, it would seem that some beneficial effect has been gained. The effect is picturesque, and the merchants are the best judges as to the extent to which they accomplish their purpose. It is to be borne in mind that the street is also lighted by the city, and Mr. L. C. Newsom, manager of the Columbus Electric Light and Power Company, to whom we are indebted for our information, states that there are over 1,000 lights in public service throughout the city. The spirit of progress is evidently active in Columbus, despite dull times.

COPPER CONSUMPTION.

THE course of the market for copper is of great interest at all times to electricians generally, and at the present moment the conditions present a problem more than usually worthy of study. Copper enters so largely into all classes of heavy electrical work that a slight variation in price causes an appreciable difference in the calculations. The subjoined table gives an idea how things have been going in recent years:

Copper Consumption.—Metric Tons.

	1893.	1894.	1895.	1896.	Increase or decrease.
Germany	60.513	62,955	70,349	85,371	+ 14,922
France	33,886	31,837	40,323	49,007	+ 8,684
England	96,615	90,069	91,084	115,557	+ 24,473
United States	77,433	94,511	108,000	93,698	— 14,302
Totals	268,447	279,372	309,756	343,633	+ 33,777
World's product'n.	303,530	324,405	334,105	370,000	.....

The question arises, How far is recovery in consumption going this year in the United States, and what will be the effect on prices? The range has been as follows: For Lake Copper, 11.55 cents in 1892; 10.75 in 1893; 9.56 in 1894; 10.75 in 1895, and 10.88 in 1896. Prices have been stiffening here for some time, and apparently with reason, consumption having easily kept up with production so far. At the present time, electrical work here has been exhibiting many signs of renewed hope and activity, while in Europe the new régime of electric traction has but barely begun to be active.

THE annual report of the American Bell Telephone Company is a very interesting document, and the figures of the growth of the industry are remarkably impressive. At the rate of 2,630,071 connections a day, the grand total is reached, for the year, of just short of 1,000,000,000. Leaving out Sundays would bring this down, but on the other hand, the work of the numerous independent exchanges would bring it up again; so that as a reasonably approximate figure it will stand. And to think that men, not women, do all this talking—the women serving merely as intermediaries!

A GIGANTIC underground railroad scheme is proposed for Chicago, the object being to make a belt line connecting all the various steam railroads. It is said that the Illinois Central and Northwestern roads are interested in this project, upon the engineering preliminaries of which experts are already engaged. Cars would be run frequently on a 5-cent fare, and the general public would be admitted as well as transfer passengers, to whom the convenience and saving in time would be enormous. The plan for the interior finish is to use yellow enamel brick. A depth of from 30 to 60 feet and a diameter of 14 feet are contemplated. The lighting would be wholly electrical and the operation of the cars would in all probability be electrical also. The cost is put at about $10,000,000, and a gross income of about $600,000 per year is figured upon. There are many merits in the scheme; and it is to be hoped it may be carried out. The soft nature of the Chicago sub-soil should render tunneling easy, although water is likely to be abundant and the line of the Chicago River must be crossed.

BETWEEN this country and Venezuela relations tend steadily to become closer, not merely because we have intervened to protect a sister republic from apparent spoliation, but because the natural conditions of our Mediterranean make trade more and more desirable with the countries bordering its southern shore. We are now glad to note that Mr. Henry Clews and other well-known New York bankers have made a contract with the Venezuelan government under which they will control and operate cable, telegraph and telephone lines for a period of thirty years, with opportunity for renewal. It is obvious that this not only opens up a better market in Venezuela for American electrical material, but for skilled American electrical engineers and operators. The development of this work will be followed with much interest.

THE amount of "mental anguish" caused by late trains, slow telegrams, busy telephone wires, or dilatory mails, has always been difficult to determine from the standpoint of value to the injured party seeking redress in a court of law; and, as a result, while ready to grant damages provable concretely on a cash footing, the courts have looked askance on mere "mental anguish" claims. One man's torment may be another man's source of joy, and it is very hard at any time to ascertain to what extent a given occurrence may have caused pleasure or pain. Away off in Minnesota, however, they have clear notions on this point, and a bill has just been passed, aimed at telegraph companies, giving "mental anguish" a limit value of $400. We regret to note there is no provision in the bill for the use of the modern scientific instruments which help psychological experts to determine the exact effect on the mind of certain conditions and actions. With the use of these and a scale or gauge, the damages obtainable under the bill could be worked out to a nicety.

LETTERS TO THE EDITOR

ELECTRICAL ENGINEERING ON OLD STEAM ROADS.

THERE seems to be considerable comment regarding the use of the third rail and trolley by the N. Y., N. H. & H. R. R. I do not think anything has been published giving exact information as to the leakage and operating expense of these two experiments. The general statement that no appreciable leakage existed seems to be doubted by at least two electrical engineers, and if these two engineers are correct in what they say I do not suppose anything but a generalization of the subject can be given, even by the electrical engineers of the railroad company. I had occasion to look into the matter some little while ago in connection with adopting some of the good points of the N. Y., N. H. & H. R. R. experiment, if I found any. My conversation with the chief electrical engineer led me to believe that my best method to obtain the information was by observation, and what I could obtain from those under him. Taking all the views of these men into consideration, I found that my trip East was not productive of great results. In fact, a large company like the N. Y., N. H. & H. R. R. had gone into the subject without consulting with any practical engineer with the exception of the engineers of the contracting parties, and their judgment does not seem to have been given very much thought.

The junk pile of brass bonds and circuit breaker parts was quite formidable, showing that some errors had been made. The force of men employed in keeping the third rail in shape attested to some difficulties in this line. The care with which the laborers handled the cables connecting the ends of the third rail at the crossings showed that they at least considered it "hot stuff." The spare (?) armatures in the car house would witness to the carefulness of the railroad company in providing against burn-outs. But enough said! Railroads contemplating electrifying their steam equipment will do well to employ competent electrical engineers.

WESTERN ELECTRICIAN.

Chicago, Ill., March 26, 1897.

THE MORSE ALPHABET FOR DEAF MUTES.

I NOTE in your issue of the 24th, an article from the Boston "Transcript," saying that a physician in Texas proposes the use of the Morse alphabet—by touch—instead of the sign language for deaf mutes. The doctor thinks it would be a great improvement on the present sign method. Fifteen years ago, I was of the same opinion. While a member of the State Board of Charities, in Wisconsin, on a visit to the State Institution at Delavan, I put the Morse alphabet on a blackboard, and explained, through the teachers, how it could be used by touch—a practice that all old telegraphers understand.

The scholars were delighted, and quickly became expert in its use. But trouble arose very soon after. Naturally jealous as all deaf mutes are, when a student grasped another's arm, and began making the dots and dashes, by pressing with his fingers, another boy, looking on, became convinced that the boy talking was "making fun of him," or indulging in gossip at his expense.

With the deaf and dumb sign language, all who looked on could read; but with this secret process, it was impossible. Hence the suspicion and jealousy. The result was an order forbidding the use of the "touch talk," as the students named it.

I hope the Texas gentleman will have more success than I had.

C. H. HASKINS.

Buffalo, N. Y.

OBITUARY

COL. L. C. BAKER.

L. C. Baker, superintendent of the second district of the central division of the Western Union Telegraph Company, died at St. Louis on March 25 of heart trouble. He had been sick three weeks. Col. Baker leaves a widow and eight children. He was born in 1840 at Tuscaloosa, Ala., and entered the telegraph field as a messenger boy for the Atlantic and Pacific Telegraph Company at Louisville, Ky. His advancement was rapid. During the war Mr. Baker acted as superintendent of military telegraphs for the Confederate Army. He received the rank of Colonel. Shortly after the war Colonel Baker became identified with the Western Union Telegraph Company. He held several important positions, and in 1878 was appointed superintendent of the central division, with headquarters at St. Louis. A few weeks ago Colonel Baker fainted on the street. He was not thought to be seriously ill, and his sudden death shocked his friends.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—IV.

BY JOSEPH APPLETON.

(Copyright, 1897.)

INSTALLATION, CARE AND MAINTENANCE OF STORAGE BATTERIES.

THE success of a storage battery plant depends largely on the way in which it is installed and put into operation. This, of course, is true of any electrical apparatus, but especially so in the case of storage batteries where the operation depends on certain chemical action and reaction being repeated indefinitely. If the elements are once properly prepared for this action the repetition is a matter of course, provided a certain amount of attention is given to the battery; but it may be safely said that a storage battery does not require more attention than, if it does as much, as other portions of an electric lighting or power plant.

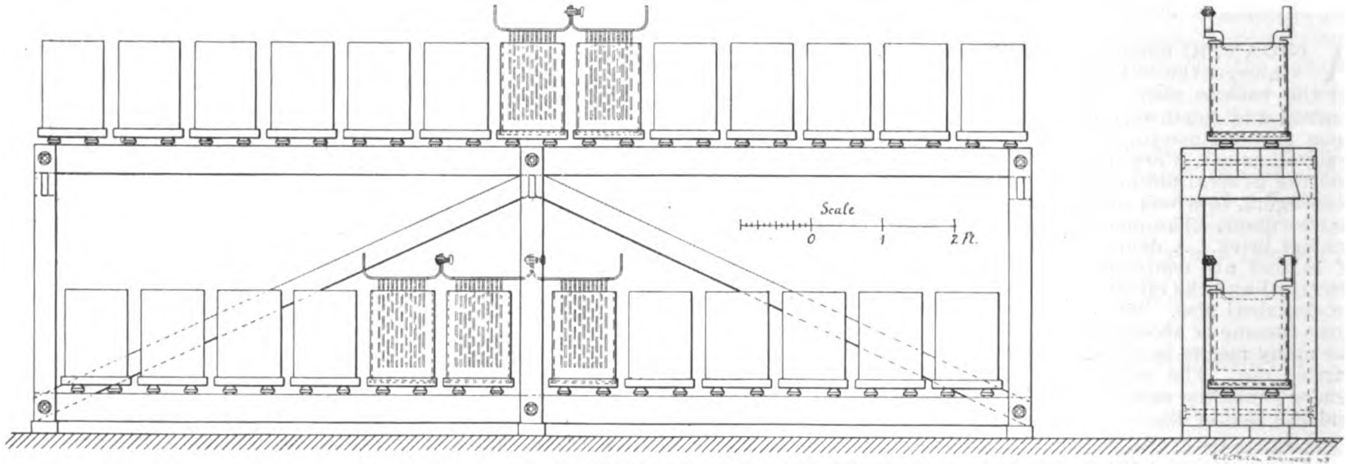

FIG. 11.—WOODEN STORAGE BATTERY STAND.

The work of installing or setting up a storage battery does not necessitate such skilled labor as the erection of engines, dynamos and similar high-class machinery, for the same accurate fitting is not necessary. It requires, however, just as much care on the part of the workman, together with strict observance of certain rules and precautions. The work differs from that connected with any other branch of electrical engineering as the principles involved are of a nature quite distinct; yet when thoroughly understood they are entirely within the province of the average mechanic.

In considering the installation or setting up of a storage battery, the subject may be conveniently divided into two sections, the methods employed being different.

1. Where the size of the cell is such that it can be handled and lifted when assembled.

2. Where the cells are too large and heavy to be handled in this way, and have to be assembled in position.

In the first case the containing cells are usually of glass, hard rubber being used occasionally where there is liability to breakage. For the larger cells, lead lined wooden tanks or solid lead boxes are used.

The selection of a suitable battery room is the first point to be considered, and in these days, when every cubic foot of space in buildings, especially those located in cities, is so valuable, the choice is very limited, and it requires much thought and ingenuity to find and utilize, to best advantage, what is available for the purpose.

The battery room should be dry, well lighted and ventilated and of moderate temperature; otherwise, the evaporation of the electrolyte is a troublesome item. Exposed iron work should be avoided as the acid fumes will in time, corrode or attack the same Whatever metal work there is exposed must be protected with an acid proof paint. The floor is best constructed of brick, tile or concrete, laid in such a manner that it will drain readily, an outlet being provided for the liquid. Where a wooden floor already exists, that portion on which the battery stands, should be covered with a lead tray to protect the woodwork from the action of the acid.

The battery room is preferably located as near the generating plant as possible, thus reducing the cost of wiring between battery and switchboard to a minimum. It is important that the cells be arranged so that all of them are easily accessible for the purpose of inspection and overhauling. The best arrangement, especially with large cells, is in one tier, but with smaller batteries there is very seldom sufficient space for this arrangement, and two and even three tiers are usually necessary. Suitable stands or racks are required to receive the cells. Figs. 11 and 12 show some designs which may be used for cells of moderate size and weight.

Where glass jars or containing cells are used they are generally mounted in shallow wooden trays filled with sand to form an even bed for the cell; these trays are supported on suitable insulators to ensure good insulation from the ground, also between cell and cell. Figs. 13, 14, and 15 show insulators of the single and double petticoat type, also an oil insulator, which is frequently used.

Where lead lined wooden tanks are used the trays are dispensed with, the tanks resting directly on the insulators. When the containing cell is of glass the elements, or plates, usually either rest on ridges which are molded in the bottom of the jar, or hang from the top of the jar by means of suitable lugs, cast on the plates for this purpose; the latter method is preferable, as it allows a perfectly clear space to be maintained between the elements and the bottom of the jar, where any sediment or deposit may accumulate.

In the larger types of cell which are provided with a lead-lined wooden tank, the same arrangement can be carried out by supporting the plates on pieces of glass which rest on lead strips placed in the bottom of the tank, Fig. 2, p. 322.

In the smaller sizes of cells, the plates of like polarity are usually connected together by means of a lead strap which is cast or welded on the plates, and forms a lug or terminal for connecting one cell to another in series, the connections between cell and cell being made either by a screw clamp or weld. In the larger sizes this method does not provide sufficient carrying capacity in the connections for the large amount of current which has to be carried; so different arrangements have to be made.

Attention may here be called to the great importance of providing sufficient sectional area in connections of storage batteries. It is, of course, imperative that for this purpose there be employed a metal impervious to the action of the acid, and the resistance of such metals is high; lead, for example, being seven times the resistance of copper. Therefore, the sectional area must be correspondingly large. If inadequate carrying capacity is allowed in the connections the various plates in the cell are worked unevenly and the full capacity of the battery is not obtained.

Probably the most satisfactory method in large cells is to burn or weld the positive plates of one cell and the negative plates of the next to the same lead strap or bus bar, thus ensuring a good connection between the similar plates in a cell, also between cell and cell in the series.

Where very heavy currents have to be carried, these lead bus bars can be reinforced by a copper conductor embedded in them, so that it is protected from the electrolytic action.

The welding or lead burning is accomplished by means of a hydrogen flame which has the special property of preventing the oxidation of the two lead surfaces which are to be fused or welded. This process is carried out as follows: Hydrogen gas is generated in a vessel from zinc and sulphuric acid, the gas is collected and passed through a water bottle to a burner where it is mixed with air forced into the burner by means of a pump, or bellows, the mixture being ignited and used as the welding flame.

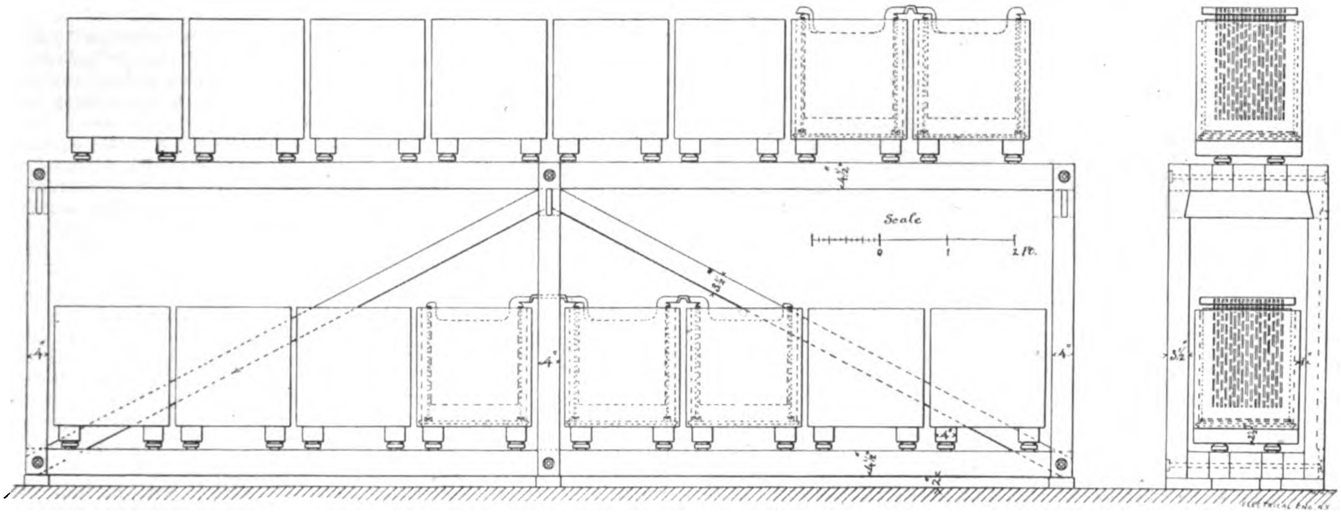

FIG. 12.—WOODEN STORAGE BATTERY STAND.

This method of lead burning is also used for making the seams in the lead lined tanks and is the only practical process by which a perfect and homogeneous joint can be made between two pieces of lead, without the introduction of solder or other substances which contain material liable to corrosion under the action of the acid. The process is quite simple and can be readily carried out by an ordinary workman after a little practice. The burning required for making seams in the 4 or 5-pound lead, such as is used for lining tanks, is more difficult on account of the liability to burn through the thin lead surface. Considerable practice is required for this work.

Fig. 16 shows a complete lead-burning outfit, such as is used for battery work.

The writer's experience, gathered from the handling of every well-known type of cell, in Europe and this country, has proved that certain simple points must be observed in setting up a battery in order to obtain the best results; naturally each particular type of cell has its peculiarities, yet the following general remarks apply to all storage batteries.

When the cells are received from the manufacturer assembled or "burned up," that is, with the plates connected in groups to form the complete element; it is best to proceed to set them up and prepare for the charging in the following way:

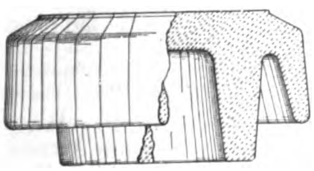

FIG. 13.—SINGLE PETTICOAT INSULATOR.

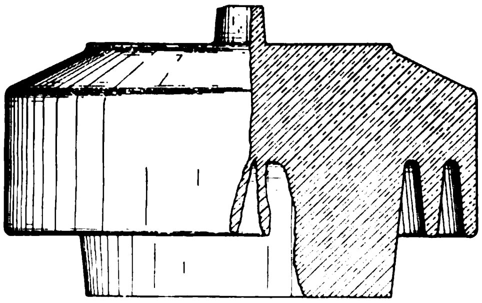

FIG. 14. - DOUBLE PETTICOAT INSULATOR.

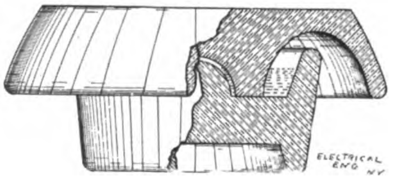

FIG. 15.—OIL INSULATOR.

Unpack the elements and containing cells carefully; see that all dust and foreign material is removed, especially any particles of metal which might accidentally lodge between the plates and form a short circuit.

Be sure that all the insulating pieces or separators are in their proper position between the positive and negative plates, and that all the plates are in proper alignment.

Place the element carefully in the containing cell on the stands or racks, taking care not to disturb the separators.

Connect the cells up in series, that is, positive terminal of one cell to negative of the next, and so on, being sure that the lead is scraped clean and bright before connecting; the positive terminal can always be recognized by the plates being a dark brown, while the negatives are gray.

When this is completed and the entire battery is connected up, it is ready for the addition of the acid or electrolyte and receiving the first charge.

If the cells are too large to ship from the factory assembled, the method of procedure is different. The plates are then handled separately and are so placed in position in the tank with the separators between them. They are then burned on to the lead bus bar as previously described.

A point of the utmost importance is the purity of the electrolyte. Ordinary sulphuric acid contains many impurities which are very injurious to the storage battery plate, notably, hydrochloric and nitric acids, iron, arsenic and copper. Only the best acid, manufactured from sulphur should be used, and tests should be made to ascertain if it is free from above mentioned substances before being accepted. The sulphuric acid made from pyrites is not suitable for storage battery work, as it contains far more impurities than that prepared from sulphur. The acid should always be diluted with distilled water, as ordinary spring or town water contains sufficient chlorine to be injurious. In diluting strong acid, always pour the acid into the water; never pour the water into the acid. The mixing should be done carefully on account of the heat which is generated. It is usual, however, to furnish the electrolyte ready mixed to the proper specific gravity. Too much care cannot be given to this question of pure acid and water as it affects very seriously the ultimate working and durability of the battery.

The following simple tests are sufficient to show whether the electrolyte is good enough for use before being put into the cells:

Test for Hydrochloric Acid.—Take a small sample of the diluted acid, which it is proposed to use for electrolyte, and add two or three drops of nitric acid, HNO_3; heat this in a test tube and allow to cool, then add two or three drops of nitrate of silver, $AgNO_3$. If the acid is pure there should be no precipitate or cloudy appearance. A very slight trace of hydrochloric acid may give a little cloudy appearance. If the solution is heated after the nitrate of silver has been added the test is more delicate. For ordinary practical use the acid may be considered satisfactory if there is only a very slight sign of cloudy appearance when the solution is cold.

Test for Nitric Acid.—Make a solution of diphenylamine, $NH(C_6H_5)_2$, made in the following way: ½ gm. $NH(C_6H_5)_2$, 100 cc. strong sulphuric acid, H_2SO_4, and 20 cc. of water, H_2O; put a small quantity of this solution in a test tube and pour on top a small quantity of the diluted acid to be tested. The presence of nitric acid will be shown by the appearance of a blue color. This test should only be used in the case of new acid; after the acid has been used as electrolyte for cells the results obtained will not be reliable, on account of certain electrolytic actions.

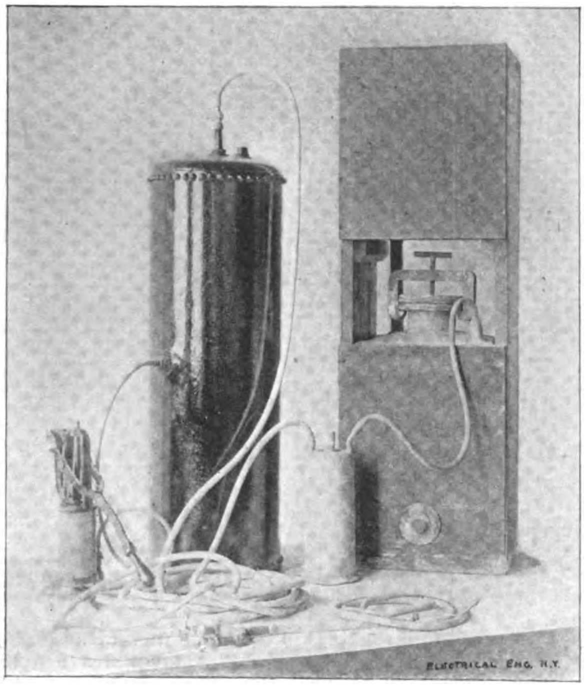

Fig. 16.—Complete Lead Burning Outfit, Consisting of Generator, Wash Bottle, Air Pump and Reservoir, with Rubber Hose and Burner.

Test for Copper and Arsenic.—Take a fresh solution of hydrogen sulphide, H_2S, add an equal quantity of the diluted acid. If the acid is not diluted a white precipitate is thrown down; this shows the acid is too strong and must be further diluted. If the sample of acid is free from copper and arsenic there should be no precipitate; if a black precipitate is thrown down it shows the presence of an impurity, generally copper; and if a yellow precipitate is thrown down it shows the presence of arsenic.

Test for Iron.—Take a small quantity of the diluted acid to be tested and add a few drops of nitric acid, HNO_3, and heat; when cold add a few drops of solution of potassium-sulphocyanide, $KCNS$; if iron is present it will be shown by the appearance of a deep red color.

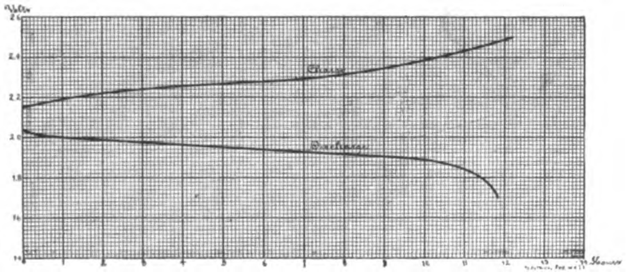

Fig. 17.—Charge and Discharge Curves.

The electrolyte should never be put into the cells until the charging current is available, as the plates are injured by being allowed to stand in the electrolyte in an uncharged condition.

The first charge differs from subsequent charges, inasmuch as it practically completes the formation of the plates and consequently has to be continued for a much longer period than is necessary for charging the battery in the ordinary work.

Before starting the charge, care must be taken that the polarity of the charging current is right. The positive pole of the battery must always be connected with the positive pole of the charging source. The voltage required at the commencement of a charge is about 2 volts per cell and this rises to 2.6 volts per cell at the end of charge, while the normal rate is maintained. Fig. 17 shows curves of voltage during charge and discharge of a cell, the current in each case being maintained at the normal rate. This curve is plotted from the readings of a test made by the writer, but being a laboratory test with a single cell, the efficiency is somewhat higher than usually obtained with a battery in ordinary commercial service.

It is important that the first charge be continued without interruption for at least ten consecutive hours; if practical a continuous run of 20 or 30 hours is preferable. The charge usually required in starting up a battery is about twice its capacity, and should be given at normal rates. This may vary somewhat with different types of cells.

The specific gravity of the electrolyte will drop during the first few hours after being put into the cells, but will rise as the charge progresses until it reaches its maximum point. For example, if the electrolyte is put into the cells at a specific gravity of 1,200, it will drop to about 1,180, and subsequently rise to about 1,210, when the first charge is completed. These figures will depend, of course, on the quantity of electrolyte in the cell, but under normal conditions are as above stated.

As the charge progresses and nears completion it will be found that bubbles of gas are given off from both plates; this is due to the fact that the active material is becoming fully formed and cannot take up all the hydrogen and oxygen gas set free by the decomposition of the electrolyte. If the charging current is reduced, this gassing will decrease, as the amount of gas liberated is in proportion to the current passing. It is always best to reduce the charging current when the gassing becomes very great, both in the first and subsequent charges.

With the pasted type of plate the question of the first charge is more vital than with the Planté type, there being danger in the former of a coating of sulphate of lead forming between the active material and the grid, if the plates are allowed to stand in the acid before the charge is commenced, or if the first charge is stopped before the plates are thoroughly formed. If a pasted plate is once allowed to become badly sulphated in this manner, it is very difficult, if not impossible, to get it back into first-class condition again, as the sulphate insulates the active material from the grid, causing all the action to take place on the grid instead of on the active material. Growing, buckling and disintegration of the active material will soon occur under these conditions. This applies to the positive plate, the negative not being injured in the same way, as it is possible to reduce the sulphate to a spongy lead more easily than to oxidize it.

This same trouble will occur with pasted plates during the regular operation of the battery if the cells are discharged too much, and allowed to stand in that condition, or if they are not fully charged at frequent intervals. The Planté plate is not liable to this trouble, the active material being a coating or portion of the plate itself, and not in the form of a layer which is dependent on the contact with the grid or plate to make and keep it active.

It will thus be readily seen that the Planté plate has advantages over the pasted plate, and now that manufacturers can give practically the same capacity for weight as with the pasted type, together with the capability of higher discharge rates, there remains but little in favor of the latter type.

Having described the method of setting up and giving the battery the first charge we will next proceed to the handling and operation in ordinary work.

THE NEW ELEMENT, "ELECTRATE."

Scientists are discussing a new element called "Electrate," the action of which is termed "Electrolysis." This is formed from free electricity, resulting from imperfect insulation, combining with foreign elements of the atmosphere.—Southern Architect.

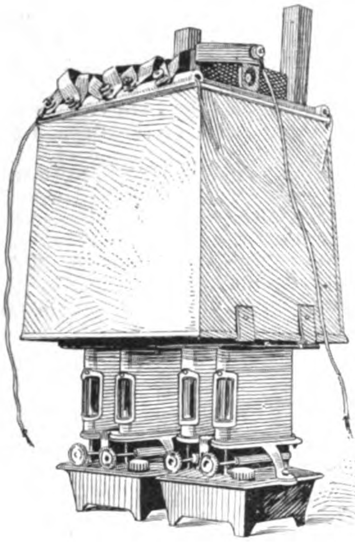
It is believed that stringent laws against undesirable immigration may produce beneficial results in protecting the body politic from the ravages of this new element.

THE CHAMPS-ELYSEES, Paris, is likely to have an electric road across it. The plan is defended by the Socialists, who say that it is a struggle between the frock coats and the blouses. People around the Rond Point don't like the idea.

THE ESSICK BLUESTONE HEAT CELL.

THE desire to convert the energy of heat directly into electric current energy has recently given birth to a number of devices for consuming carbon directly in batteries. Working in a somewhat different direction, Mr. H. V. Essick, of Yonkers, N. Y., has thought to utilize heat energy to increase the activity and output of the well-known copper-sulphate cell with zinc-copper electrodes, such as the gravity cell, and with that end in view has constructed and recently patented the battery illustrated in the accompanying engraving.

This generator is built up of units consisting of an outer cell of copper with a zinc plate suspended in the center and insulated from the copper. The copper sulphate is fed automatically to the cells in the shape of a solution and in proportion to the activity of the cell. A lamp or other source of heat is placed under the cells which heats the electrolyte to a temperature of 180 degs. Fahr., after which a small quantity of heat only is required to maintain that temperature.



THE ESSICK BLUESTONE HEAT CELL.

With cells occupying only 1 cubic foot of space Mr. Essick states that he is able to obtain 75 watts, for which, ordinarily, 150 gravity cells would be required. Each cell delivers 15 amperes at 1 volt, or 15 watts; some cells even show as high as 38 amperes. We understand that Mr. Essick will shortly place his cell on the market, arrangements now being in progress with that end in view.

FLUX OF FORCE AND COMMUTATORLESS DYNAMOS.

BY A. DE PUYDT AND M. PONCIN.

IN speaking of "flux of force," it seems to us that the following points are usually forgotten: 1. That it is the bodies themselves which act one upon the other, a flux of force being only the measure of that action at a point. 2. That one body in order to move another, must act as its fulcrum.

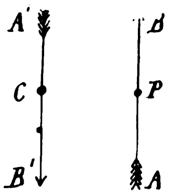
In other words, it seems to be forgotten that one material point cannot exert a force upon another material point in any other direction than that of the straight line joining them.

For example, in electro-magnetism it is said that if C is a rectilineal conductor perpendicular to the paper and carrying an electric current and P a magnetic pole, C will tend to make P move in the direction of the arrow A B, and P will tend to make C move in the direction A′ B′. (See diagram.) This, it will be seen, is impossible because there is no fulcrum in either of the cases.

Speaking generally, all the pretended actions of one body upon another are impossible, if they cannot be explained by the resultant of the attractions or repulsions in a straight line of each point of the one body upon each point of the other. Our opinion is that in the similar actions between conductors and magnets, every portion of the conductor acts as the fulcrum for the rest of the system.

These considerations have led us to make a non-polar dynamo, in which the bars wherein the electric current is induced revolve with the inductors, which renders the construction very simple and very strong. The fulcrum of the whole mobile system is here the external circuit, that is, the fixed part of the electric circuit mains, etc.

The result of these reasonings is that we are now able to make a commutatorless continuous current dynamo, essentially practical and strong, giving a very high efficiency, working without attendance, and without sparking, no matter what fluctuations there may be in the load, a very important point in a great many cases.[1]



ELECTRIC TRANSPORTATION

THE G. E. CO'S EXPERIMENTAL TRACK AT SCHENECTADY.

THE trend taken by the electric railway industry in the direction of the field hitherto occupied exclusively by the steam locomotive, as evinced by the recent developments on the New York, New Haven and Hartford and Baltimore and Ohio Railroads, has caused the General Electric Company to provide itself with its own special line of track upon which to carry out electric traction experiments. The line of track lies between the works at Schenectady and the Erie Canal. It has been laid upon the heel path, is 6,700 feet long, and is of the regulation New York Central Railroad construction, the service rails being standard rails, 85 pounds to the yard. It is upon this track that almost daily equipments are tried under different steam road conditions and bursts of speed made and efficiencies recorded of a more than encouraging nature.

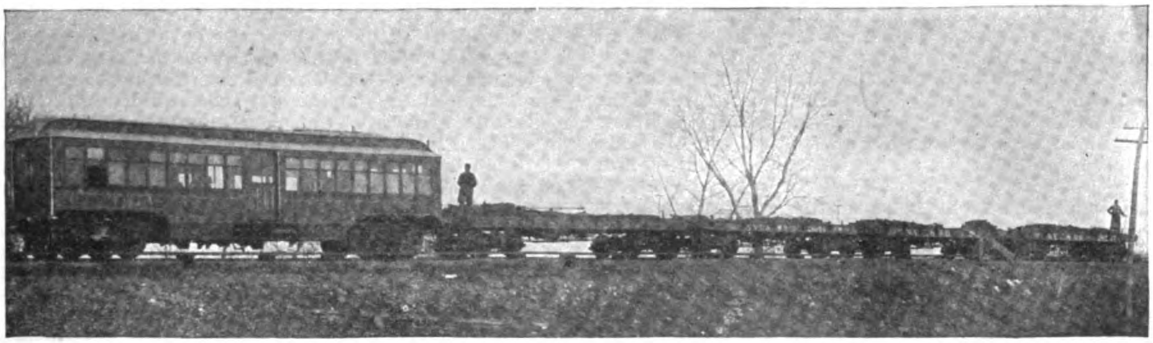


FIG. 1.—MOTOR CAR HAULING FOUR LOADED FLAT CARS ON GENERAL ELECTRIC EXPERIMENTAL TRACK.

The track is laid from the side of building No. 7, and crossing the river road rises on a gradient of 4 per cent. to the level of the heel path. The first section of the line is a tangent 2,415 feet long, the second a series of short tangents and curves

---

[1] See Elec. Engr., p. 213, Feb. 24, 1897.

1,635 feet long, and the third another tangent 2,730 feet in length.

Running beside the track on the far side from the canal are the conductor rails. Of these there are two, running parallel with each other and the track, from the top of the first gradient to the end of the line. They are of 30-pound rails, set on 8-inch ash blocks treated with bergtheer in vacuum pans and thoroughly impregnated. The two sets of conductor rails have been laid down for the purpose of experiment with alternating multiphase currents. For direct current experiments two rails are connected in multiple. Both service and conductor rails are bonded with No. 0000 copper bonds.

The current is taken from the works power house, over a line issuing from the back of the testing department. The feeder is a 500,000 c. m. insulated cable, running by the track for a distance of about 5,300 feet. The line is divided into three working sections, each controlled by its own switch and semaphore. When this switch is closed its section of conductor is made alive, and the movement of the switch handle sets the semaphore.

The experiments made so far have been carried on for the purpose of developing motors and systems of operation for elevated and surface steam roads. For locomotive a special eight-wheeled car is used. This resembles a regular passenger coach so constructed as to give an unobstructed access to the two motor trucks. The weight of this coach-locomotive equipped is about 30 tons empty. It is divided into three sections: a driving and testing department in front; a passenger division in the center, and a rear compartment in which are carried the air pump, tools, etc.

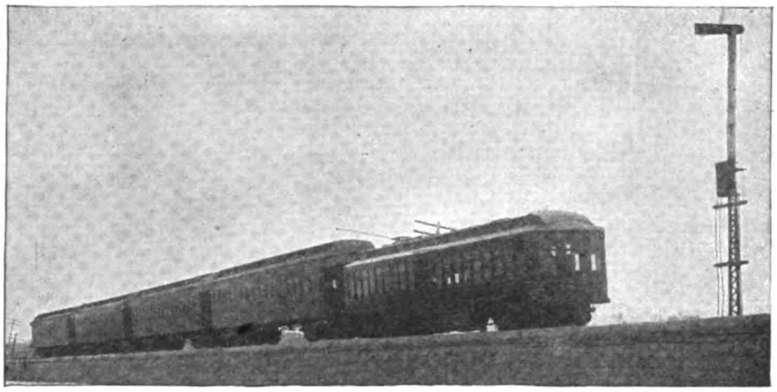

Fig. 2.—G. E. Motor Car Hauling Four Standard Passenger Coaches.

The equipment of the forward compartment consists of a skeleton wooden switchboard carrying the ammeters, voltmeters, wattmeters, etc., to enable the engineer to gauge exactly and record the performance of, the specific motor equipment which may be under experiment at any stated time. In addition the switchboard is fitted with the necessary quick break switches, magnetic blow-out, fuse boxes, automatic circuit breakers, etc. The controller is set in front of the right forward front windows, through which the driving engineer has an unobstructed view of the track in front of him. To his right is the valve handle of the air brake, and in front of him is an operating ammeter gauging the current output. The resistances are suspended from beneath the central compartment.

In the test during which the photographs from which our illustrations were made, the equipment of the car consisted of four G. E. 2,000 motors—each motor being rated at about 125 horse power—one motor to each axle, motion being communicated to the wheels through steel gear and pinion. The forward truck was equipped with a special speed recorder. The controller used was a K 16 series parallel controller.

From beneath the bolster of each truck set between the wheels on the conductor rails' side projects a heavy oak beam, to which is suspended the contact shoe by means of which the current is brought from rails to motors. This shoe is a flat piece of cast iron with the ends slightly curved. It is fastened by two loose links to an iron casting bolted to the oak beam. This method of suspension keeps the shoe continuously in contact with the surface of the conductor rail as it allows it to conform immediately to any inequalities which may occur in the latter.

The air for the brakes and whistle, one of which is set at each end of the car, is furnished by a vertical direct connected air pump, operated by a motor controlled automatically.

The first test made with the motor equipment, the total drawbar pull of which is about 15,000 pounds, consisted in the hauling of three flat New York Central and one flat Lake Shore freight cars each loaded with pigs of iron. This load, about 121 tons dead weight, was easily handled by the locomotive, and the records as to speed and power required showed most gratifying results. The flat cars were then switched back into the works. This train is shown in Fig. 1.

The locomotive was then coupled to four New York Central standard passenger coaches, making with the motor car a train of 130 tons. The controller was in charge of Chief Engineer W. B. Potter, and Mr. S. H. Libby acted as conductor. Several interesting runs were made with this train up and down the track, with equally encouraging results.

ELECTRIC TRACTION TRIALS ON BELGIAN RAILROADS.

According to "l'Electricien" the Belgian State Railway will this year experiment with electric traction on a line of railway from Brussels to Tervueren, a distance of about nine miles. Five large accumulator cars will be run in addition to the present steam service. They are to run at a speed of 18½ miles an hour on the steepest gradient (1.6 per cent.), and at 31 miles an hour on other parts of the line. Each car will be 52½ feet long, and will rest on two bogies. There will be room for 80 passengers. The cars are direct-driven, and there are two motors on each. The motors will weigh from eight to nine tons, the other electrical apparatus one ton, the cells twelve tons, and the car twenty tons. Three Julien and two Tudor batteries have been ordered, each of 264 cells. The former are designed to make three or perhaps four journeys without recharging, the latter only one journey. In the latter case, however, the time required for charging is limited to one hour, while for the Julien battery six hours are required. The cells are in 24 drawers, 11 being contained in an ebonite box in each drawer. Although the railway administration's specification, when ordering the batteries, was somewhat exacting, the object of the test is actually to compare various types of motors, to find which are the most suitable for drawing considerable loads at fast speed on ordinary railroads. The following firms are supplying motors for these trials: Jaspar of Liege, Pieper of Liege, Schuckert of Nuremberg, and Thury of Geneva. The motors will be compound-wound and connected long shunt, the winding in series with the armature constituting part of the starting resistance. The following are some of the conditions specified for the motors: At a pressure of 500 volts the two motors of a car when connected in series shall revolve at 116 revolutions per minute, when the current is 15 amperes, and the field-magnets are only excited by the shunt winding. Under these conditions they shall have an efficiency of at least 75 per cent. When connected in parallel at 500 volts, with the maximum excitation obtainable by the shunt alone, and a total current of 150 amperes, the motors shall make 231 revolutions per minute, and the commercial efficiency shall not be less than 80 per cent. The cells will be charged by a Willans engine and dynamo, erected on a car drawn by an old locomotive.

OPERATING ST. LOUIS UNION DEPOT BY ELECTRIC LOCOMOTIVES.

The Board of Directors of the Terminal Railroad Association, St. Louis, have under consideration the problem of changing the motive power of the terminal system from steam to electricity. The idea of the Terminal Association is to dispense with its steam locomotives entirely, and move by electricity all trains that enter the city. About 150 passenger trains per day enter the passenger station at Eighteenth street, and the number of freight trains is many times greater. All these will be hauled over the terminal tracks by electric locomotives if a practical solution of the problem can be had.

In addition to this, the company hopes to be able to do all of its switching in St. Louis, East St. Louis and Madison with the same improved devices.

In discussing the company's plans, President Walsh instanced the Baltimore and Ohio Company, which supplied its surplus power at the Baltimore tunnel to other users of electricity. "If we adopt the new motive power," he added, "I suppose we would follow the same plan. The cost of operation could be considerably reduced in that manner. It might be possible to furnish the current for street railways and other plants, and build up a profitable business. The coal consumption of a big station would not be any greater than, and possibly not so great as, that of our fifty locomotives."

ELECTRICITY ON ILLINOIS CENTRAL.

Since the World's Fair, the Illinois Central Company has given close attention to the developments in the electrical appliances for the operation of passenger trains, in the expectation that electricity might ultimately be substituted with profit for steam as a motive power for its suburban service. In 1892 reports on this subject were made to the company by its chief engineer and superintendent of machinery. Last autumn these officers, together with the general superintendent, were appointed a committee to investigate and report upon the practicability of introducing electricity in the place of steam power in the operation of the company's trains. The committee, after an exhaustive investigation, submitted their report, March 12, and at a meeting of the board of directors of the company, held in New York, on the 25th, the board formally approved the substitution of electric power for steam in the operation of its local suburban trains, and authorized the president to take the necessary steps to carry out the order of the board. It is said that preference is given to the third rail method.

WILL SHIFT CARS BY ELECTRICITY.

The Pittsburg, Bessemer and Lake Erie is understood to be arranging to shift cars at the Pittsburg end of the line by means of electricity. According to the reports they are preparing plans for great yards along the Union railway. Realizing the necessity for the most economical measures in order to enable them to handle ore and other freight at the minimum of expense they will erect a large power plant and use electric motors to move the cars. It is said that a great part of the expense incurred in handling freight destined for the mills and furnaces is occasioned by the necessity for using steam locomotives.

TROLLEY ON THE HUDSON FERRIES.

A new plan fostered by the Consolidated road of New Jersey and the Brooklyn Heights road is to connect directly by the Pennsylvania Annex ferry boats on the Hudson and interchange trolley cars and trips over the two great systems without change. Over 400 miles of track will be available.

SOCIETY & CLUB NOTES

NEW YORK ELECTRICAL SOCIETY.

Mr. E. E. Higgins, editor of the "Street Railway Journal," will lecture at Columbia University, New York City, on April 7, at 8 P. M., before the New York Electrical Society, on "Résumé of Financial and Engineering Practice in American Street Railroading." This is an excellent opportunity to hear an important topic discussed by a master of the subject.

THE FRANKLIN INSTITUTE, Philadelphia, is discussing a textile exhibition for September, 1897. Mr. J. M. Dodge advocates the use of electric and compressed air motors for driving the machinery, and proposes that all the apparatus on view should be kept running. The scheme has not yet passed beyond the stage of discussion.

LEGAL NOTES

SUB-TROLLEY FREEDOM FROM ELECTROLYTIC ACTION.

The Metropolitan Street Railway Company, of New York City, to satisfy itself not less than to demonstrate the fact to the State Railroad Commissioners, has recently made a large number of tests on its Lenox avenue conduit line, to ascertain if there could be any electrolytic action. The results show no action from the railway circuits.

THE CONSOLIDATED CAR HEATING COMPANY, Albany, N. Y., has appealed the cases involved in the recent Coxe decision in favor of the American Electric Heating Corporation, as to indicator switches, a decision which the Consolidated Company holds to be very limited in its scope.

REPORTS OF COMPANIES

ELECTRIC ENGINEERING AND SUPPLY CO.

At the annual meeting of the stockholders of the Electric Engineering and Supply Company, held at Syracuse, the following directors were appointed: H. C. Hodgkins, R. H. Sanderson, H. A. May, J. E. Zeublin, and J. V. Clark. At the subsequent meeting of the new board of directors, Mr. H. C. Hodgkins was elected president; R. H. Sanderson, vice-president, and H. A. May, secretary and general manager. Mr. May, the new manager, has been with the company since its organization, in 1889; employed at first as bookkeeper and latterly as cashier. Owing to the able manner in which he has filled his position, in handling the finances of the company, and his thorough knowledge of every detail of the business, his promotion is a fitting tribute to his acknowledged ability. The Engineer wishes Mr. May the best of success.

PERSONAL

MR. N. D. WEBSTER, who has for the past five years been one of the most successful advertising solicitors on the staff of a well-known electrical journal, has resigned and has accepted a position with the "American Electrician." Mr. Webster is deservedly popular among the electrical trade not only in New York City, but throughout the Eastern States, and should prove himself a success in his new position.

MR. E. P. COOK, assistant superintendent of the western division of the Western Union Telegraph Company, at Dallas, Tex., has been appointed to succeed the late Col. L. C. Baker, as superintendent, with headquarters at St. Louis.

PRESIDENT F. NICHOLLS, of the National Electric Light Association, has made twelve trips to New York during his term of office, making 12,000 miles traveled by him in ten months in its interests.

MR. J. MOFFAT, secretary of the Salt Lake and Ogden Gas and Electric Light Company, has resigned in order to devote his entire attention to his mining interests.

MR. RUSSELL B. HARRISON, president of the Terre Haute, Ind., street railway, has been in the East lately, and has had to undergo an unceasing run of interrogatories as to his taking office under the McKinley administration.

Mr. H. M. BYLLESBY, of St. Paul, Minn., has been an Eastern visitor in connection with certain electrical enterprises under development.

MR. GEORGE ROSS, electrician at Union Station, St. Louis, Mo., has been tendered the position of electrician for the East St. Louis Electric Railroad, which was lately purchased by the company which operated the line on the Eads bridge. He will also act as superintendent. Mr. Michael Harrold, who has been superintendent of the East St. Louis line under the old management, will be made superintendent of some of the Scullin lines in St. Louis.

MR. J. CARL MAYRHOFER, E. E., is producing some very fine electrical effects in connection with the spectacular lecture given by Mr. Garritt P. Serviss at the Carnegie Music Hall, New York City, on "The Evolution of the Earth." The lecture is being repeated several times. The novelty and the brilliance of its effects are worthy of the highest praise.

MR. JACOB CLOOS, of Milwaukee, who is well known in the West as an expert mechanical and electrical engineer, has been appointed electrical engineer for the city of Beaver Dam, Wis.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 23, 1897.

Alarms and Signals:—

ELECTRICALLY OPERATED SIGNAL OR SEMAPHORE, J. N. Newson, St. Louis, Mo., 579,170. Filed Sept. 14, 1896.

Electrically controlled mechanism, whereby the levers are operated in opposite directions.

Batteries, Primary:—

ZINC FOR ELECTRIC BATTERIES. F. A. Lane, Torrington, Mass., 579,273. Filed Oct. 22, 1895.

Employs a protecting coating encircling the major portions of its periphery and a limited exposed portion extending along its length in the longitudinal space left in the encircling coating.

Batteries, Secondary:

METHOD OF MANUFACTURING ELECTRODES FOR SECONDARY BATTERIES. L. Epstein,, London, Eng., 579,361. Filed Sept. 5, 1896.

Consists in first rendering porous the surfaces of the lead plates, then treating them with a mixture of lead oxide and caustic alkali, then drying, and finally converting certain of the plates into negative electrode and ethers into positive electrodes by immersing them in an electrolyte.

Distribution:—

DEVICE FOR HOUSE WIRING. H. R. Young, Lakeport, N. H., 579,213. Filed Jan. 31, 1896.

Consists of a magnetized body having provision for attachment to a fishing wire and magnetized and provided at one end with hooks.

ELECTRICAL TRANSFORMER. F. H. Jeannin, Arcadia, Fla., 579,395. Filed April 1, 1895.

A core made up of soft iron wires lapped over at the ends.

Dynamos and Motors:—

ALTERNATING CURRENT DYNAMO-ELECTRIC MACHINE. C. P. Steinmetz, Schenectady, N. Y., 579,283. Filed March 20, 1896.

A transformer having primary and secondary circuits wound on its main core, a core forming a magnetic shunt to the part of the core on which the secondary is wound and a coil through which a variable current flows wound on the magnetic shunt core.

Electro-Metallurgy:—

ELECTRO-PLATING HOOK. J. Bossard, Dubuque, Iowa, 579,124. Filed April 25, 1896.

Details of construction.

ELECTRICAL AMALGAMATOR. W. Wright, New York, 579,211. Filed July 8, 1895.

Means for electrically controlling the deposit surfaces of the amalgamator.

Lamps and Appurtenances:—

VEHICLE, LIGHT, AND GOVERNOR FOR SAME. D. W. Stinson, St. Louis, Mo., 579,190. Filed Nov. 23, 1895.

Consists of an electric generator adapted to be operated by a friction disc in conjunction with a drive wheel.

ELECTRIC ARC LAMP. J. A. Mosher, Chicago, Ill., 579,161. Filed Oct. 22, 1896.

Means for mounting a small arc-inclosing envelope, so that the carbons may both be reciprocated by the regulating mechanism of the lamp.

ELECTRIC INCANDESCENT LAMP. F. L. Fowler, Philadelphia, Pa., 579,227. Filed Nov. 5, 1896.

Designed to permit the renewal of filament without difficulty.

CARBON HOLDER. C. E. Harthan, Lynn, Mass., 579,267. Filed Oct. 14, 1896.

Details of construction.

ARC LIGHT CUT-O UT. C. E. Harthan, Lynn, Mass., 579,268. Filed Oct. 14, 1896.

Details of construction.

Measurement:

ELECTRICAL MEASURING INSTRUMENT. E. J. Houston and A. E. Kennelly, Philadelphia, Pa., 579,344. Filed Oct. 27, 1896.

Consists of a permanent magnet provided with pole pieces, one of which encloses the other; a coil capable of moving in the polar channel about a fixed axis into positions corresponding to definite current strengths under the action of electromagnetic forces opposed by a definite torque and a pointer rigidly attached to the coil and moving over an indicating scale.

Miscellaneous:—

ELECTRICAL GAS COCK. F. W. Ackerman, Corning, N. Y., 579,249. Filed July 11, 1896.

Comprises a casing, an oscillating valve mounted therein and adapted to control the gas supply, an armature mounted upon the valve, and electro magnets applied in the casing so as to exert their force upon the armature at a tangent to its direction of rotation.

MEANS FOR TRANSPORTING ARTICLES OF MERCHANDISE. M. C. Mengis, Brooklyn, N. Y., 579,158. Filed April 10, 1896.

Designed for the transportation of mail matter and other small packages.

APPARATUS FOR BLEACHING FIBROUS MATERIALS. C. Kellner, Vienna, Austria-Hungary, 579,236. Filed Feb. 1, 1892.

Consists of a vessel for containing a suitable electrolyte, electrodes arranged relatively to one another to cause the electric current to follow a zigzag course, and means for bringing the material saturated with the electrolyte into contact with the electrodes.

DIAPHRAGM FOR MANUFACTURING CHLORIN AND CAUSTIC SODA BY MEANS OF ELECTROLYSIS. E. Baker, Winchester, Mass., 579,250. Filed April 6. 1895.

Composed of a body of sand having its particles united by a binder.

ELECTRIC FURNACE. W. S. Hadaway, Jr., New York, 579,324. Filed May 8, 1896.

Designed for use in burning the finer qualities of porcelain.

PROCESS OF MANUFACTURING PERCARBONATES. E. J. Constam and A. Von Hansen, Zurich, Switzerland, 579,317. Filed Sept. 4, 1896.

Consists in electrolyzing a saturated solution of carbonate at a temperature below zero centigrade.

ELECTRIC SUNSHINE ANNUNCIATOR. L. Hunt, St. Louis, Mo., 579,393. Filed Oct. 17, 1896.

Details of construction.

ELECTRIC HEATER. G. H. Whittingham, Baltimore, Md., 579,459. Filed Jan. 30, 1896.

A tubular heater in which the resistance wire has its entrance and exit at the same end of the tube and means for relieving the resistance wire of the heat generated by the passage of the electric current.

ELECTRIC TIME CHECK AND RECORDER. A. Davidson, New York, and C. G. Armstrong, Chicago, Ill., 579,473. Filed Jan. 25, 1896.

Details of construction.

ELECTRICALLY OPERATED SEWING MACHINE. J. S. Biggar, Chicago, Ill., 579,511. Filed Jan. 8, 1896.

A pair of solenoids operate the needle reciprocally, and a rotary motor rotates the shaft.

Railways and Appliances:—

ELECTROPNEUMATIC LOCOMOTIVE. G. Westinghouse, Jr., Pittsburg, Pa., 579,526. Filed March 4, 1892.

Comprises an electric motor, a vehicle driven thereby, an air-compressor, a compressed air reservoir, a fluid motor for assisting in driving the vehicle normally operated by air under pressure from reservoir.

ELECTRIC RAILWAY. E. Lachmann, Hamburg, Germany, 579,300. Filed June 12, 1895.

Embodies a main underground conduit provided with the usual surface slot, and an auxiliary conduit open at its lower end insertible into the main conduit through the slot for the purpose of drainage.

TROLLEY SUPPORT FOR ELECTRIC RAILWAY CARS. J. F. S. Branth, New York, 579,380. Filed Nov. 20, 1888.

Employs curved plate springs upon which the trolley support rocks.

CURRENT COLLECTING DEVICE FOR RAILWAY VEHICLES. G. Westinghouse, Pittsburg, Pa., 579,506. Filed June 8, 1896.

Embodies a contact head, an extensible and normally vertical supporting frame therefor, a base to which the frame is pivoted, and means for locking the contact head in its lowest position, the means being actuated by the movement of the supporting frame upon its pivot.

SYSTEM OF CIRCUITS AND APPARATUS FOR ELECTRIC RAILWAYS. G. Westinghouse, Jr., Pittsburg, Pa., Aug. 20, 1891.

Adapted for conduit systems.

ELECTRIC RAILWAY SYSTEM. G. Westinghouse, Jr., Pittsburg, Pa., 579,527. Filed Feb. 19, 1894.

A street railway built with two flat rails on one side constituting electric supply and return conductors, and grooved supporting and guiding rails on the other side.

Switches, Cut-Outs, Etc.:—

CIRCUIT BREAKER. F. C. Robertson, Toronto, Canada, 579,366. Filed July 22, 1895.

Designed for low voltage currents.

AUTOMATIC ELECTROMAGNETIC CIRCUIT BREAKER. W. E. Harrington, Philadelphia, Pa., 579,431. Filed May 5, 1896.

Comprises switch of two cores, a solenoid coil and a ratchet device, the cores movable in the magnetic field of the coil and adapted to be actuated by the current passing through the coil to actuate the switch, the ratchet device adapted and adjusted to hold the switch out of contact after having been actuated.

Telegraphs:—

TELEGRAPH CALL BELL. J. N. Newsom, St. Louis, Mo., 579,169. Filed April 27, 1896.

Details of construction.

Telephones:—

TELEPHONE SPRING JACK. W. O. Meissner, Chicago, Ill., 579,239. Filed Jan. 17, 1896.

Details of coustruction.

TELEPHONE EXCHANGE SYSTEM. J. E. Keelyn, Chicago, Ill., and K. B. Miller, Washington, D. C., 579,299. Filed April 27, 1896.

A divided-board telephone exchange system wherein the connection of two subscribers on different boards is effected by trunk lines interconnecting the boards.

TELEPHONIC MESSENGER SERVICE. J. D. Hobbs, New York, 579,482. Filed Feb. 18, 1896.

Means whereby a telephone and messenger call box may be employed in combination or independently of each other and working on the same circuit.

THE STOCK MARKET

IMPROVED CONDITIONS ALL AROUND.

The United States Supreme Court may give disquieting railway decisions and politics in Europe may continue charged with peril of war, but there can be no question as to the improvement in many conditions of American business. The first quarter of 1897 has shown a falling off of 11 per cent. in business failures over the like period in 1896 and a decline of 16 per cent. in liabilities. Bank clearings for March are the best for many months past, and 1.8 per cent. larger than for March, 1896. Recent investigations show that since November at least 100,000 persons have been added to the force at work in the main lines of industrial pursuits. This is below what was expected, but is a gain in keeping with the others. The passage of the Dingley tariff bill will take place soon and will relieve uncertainty that still holds the wheels of trade in inactivity. The high rate of duties proposed, exceeding the McKinley in some respects, gives great offense even in some Republican quarters, and there is a general wish for the settlement of the currency. What the country chiefly wants is peace.

Stock quotations have been lower through the week. Western Union on sales of 49,044 shares went off from 82½ to 80, and Mr. Sage is understood to be firm for a lower rate of dividend. General Electric on sales of 11,727 shares rose from 30½ to 31¾. American Bell telephone has gone off slightly, from 225 to 222.

TRADE NOTES & NOVELTIES

THE HOLTZER-CABOT AUTOMATIC PRESSURE CONTROLLER AND INDICATOR.

IN the article appearing in another place in this issue, describing the model station of the Narragansett Electric Lighting Company, of Providence, mention is made of the method of feeder regulation control which is about to be adopted. For this purpose, the Holtzer-Cabot automatic controller and indicator will be employed.

This apparatus furnishes the means of automatically controlling the various forms of pressure regulating devices in use at the present time, such as field rheostats, boosters, end cell switches, etc. The engraving, Fig. 1, shows its application to a field rheostat in which the driving shaft is coupled to a rheostat arm. This shaft is operated by a positive step by step movement as shown. The driving pawls are of hardened steel and engage with the phosphor-bronze gear, and are controlled by the electro-magnets so as to move the rheostat arm right or left by the engagement of one pawl or the other with the driving gear. The pawl lever is driven by a small motor, as shown, the speed of which may be varied to any extent desired. By this means the speed of regulation can be adapted to the size and corresponding lag of the generator fields. As the power of the motor is ample and the wearing parts are strongly built of the best material, it is possible to use this apparatus for operating end cell switches, feeder regulators having heavy contacts, with perfect success.

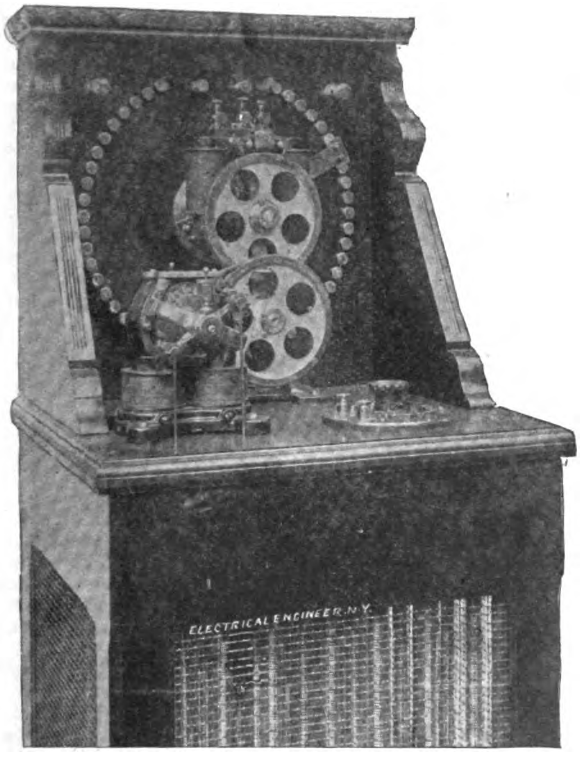

FIG. 1.—HOLTZER-CABOT AUTOMATIC PRESSURE CONTROLLER.

A pressure indicator or relay, Fig. 2, is used in connection with this controller, and recent improvements have been made which render it extremely accurate and durable. This instrument may be instantly set to operate the controller at any desired pressure and when so set the pressure will be kept at that point regardless of change in speed or load provided this variation is within the capacity of the dynamo or field rheostat. This instrument will operate the controller with a variation in pressure of half a volt on a 110-volt circuit and being of the hot wire type is free from the defects inherent to those instruments of the electro-magnetic or solenoid type.

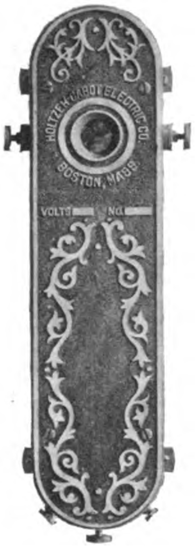

FIG. 2.—HOLTZER-CABOT AUTOMATIC PRESSURE INDICATOR.

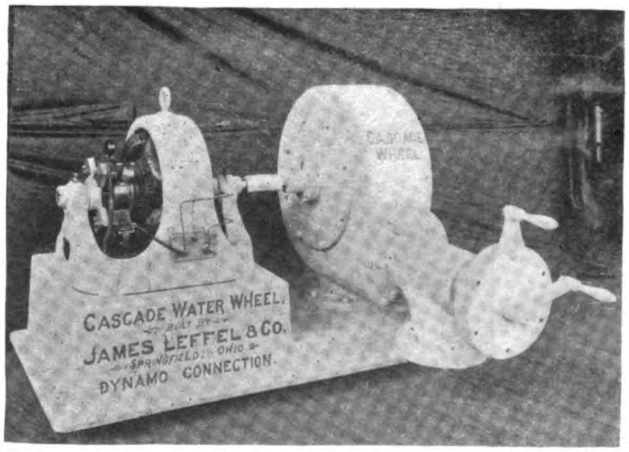
The amount of energy required to operate the entire apparatus for the largest generator is from 60 to 65 watts. It is manufactured by the Holtzer-Cabot Electric Company, of Boston, in various forms from the step-by-step movement only, belt driven, and ready to attach to any form of rheostat to the more complete form with field rheostat, coils, slate or marble head and motor contained in one cabinet.

NEW LEFFEL CASCADE WHEEL.

A VERY neat electric light installation is that in the Springfield (O.) Water Works, which furnishes light for the pumping house and the residence of the superintendent.

The plant consists of one of the new Leffel "Cascade" 12-inch water wheels, built by James Leffel & Co., of Springfield, O., coupled direct to a dynamo, as shown in the accompanying engraving. The buckets of this 12-inch wheel, which is of the impulse or reaction type, are adapted to a round stream or



NEW LEFFEL CASCADE WATER WHEEL AND DYNAMO.

nozzle of .75 of an inch as a maximum. An ingeniously arranged apparatus is used for changing the size of the nozzle tips to suit the number of lights or the capacity of the generator, which is easily and quickly done by operating a lever by hand, so that five different capacities of nozzle tips are used.

The lighting plant has a capacity of nine to forty 16-candle-power incandescent lights, and a jet of .35 of an inch will run the smallest number, under a pressure of 70 to 80 pounds from the water works pipes. For driving the forty lights a .50 to a .60 of an inch stream of water is used.

This wheel is run without a governor, as the pressure from the water works is ordinarily quite steady, ranging from 65 to 85 pounds pressure in the pipes, but the generator bears some variation in speed, and the very steady motion of the Cascade wheel prevents any serious fluctuations in the lighting.

The Cascade wheel is specially adapted to high heads where the amount of water is limited. Its advantages are the great simplicity of its structure, its slower speed, for many purposes, its small frictional surface, and its almost entire freedom from wear. Besides the foregoing good qualities, this wheel is guaranteed to give a far higher efficiency or percentage of the use of water, than any turbine under similar conditions. The wheel is also applicable to heads ranging from 40 feet to 2,000 feet and upwards; head pressures so high, that they are absolutely impossible of application to turbines.

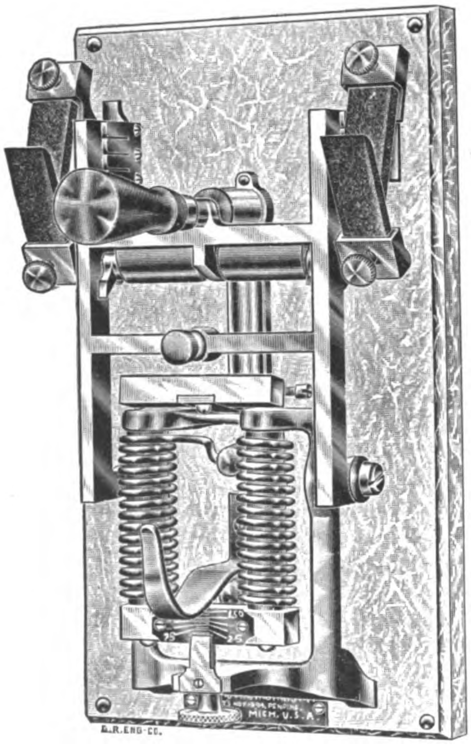
A test of the Cascade wheels was made recently under the superintendence of Prof. E. A. Hitchcock, of the Ohio State University, which showed the following remarkable results: Six tests of a 38-inch wheel gave efficiencies ranging from 87.06 to 91.02 per cent. A like number of tests on a 26-inch wheel gave efficiencies ranging from 87.76 to 91.85 per cent. In both instances the variation in efficiency noted was due to variation in water pressure which occurred during the tests. The showing is a very remarkable one.

NEWAYGO AUTOMATIC CIRCUIT BREAKERS.

FUSE wire has proved so unreliable to all users and electrical engineers as a safety device for protection from short circuits, overloads or grounds, and offering no protection from lightning storms whatever, that the electrical public has turned its attention to the use of automatic magnetic circuit breakers as a reliable substitute for fuse wire.

We illustrate in accompanying engravings the well-known automatic circuit breakers or limit switches made by the Automatic Circuit Breaker Company, of Newaygo, Mich., with their latest improvements. Fig. 1 shows the circuit breaker closed, and Fig. 2, a sectional view, after the circuit is broken.

As will be seen, the copper contact A has mounted upon it the carbon B with which the carbon B' makes the final break. The dash pot C gives the break frame R its sudden blow through the handle V; the latter has about one-eighth of an inch play, as shown at L, so that it gives the break frame a hammer blow, overcoming any possible chance for contact R and A to stick. D is a latch and E a small weight to return the armature to its place after the instrument has operated.



MICH. U.S.A.
B.R.ENG.CO.

Fig. 1.—The Newaygo Automatic Circuit Breaker.

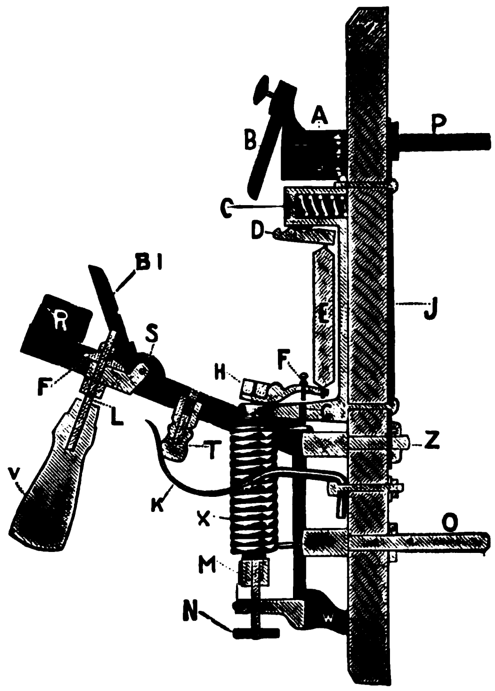


Fig. 2.—Newaygo Automatic Circuit Breaker.

The screw F through the armature holder, makes contact on the point shown at G, which is a piece of iron running to the magnet core and is magnetized so that it holds the armature up until the current exceeds the pre-determined point. Then magnet G releases the screw F, giving a hammer blow to E against latch D, and releases disc F, which is the catch on frame R, and a part of handle V, all movements being positive, knock-out blows. M is the graduation plate, the graduations being in amperes. The adjusting screw N adjusts the capacity, either increasing or decreasing to any pre-determined point between the minimum and maximum graduations. All springs and intricate parts are thus avoided by a novel use of magnetism, being points F and G, whose action is always positive and never varying in principle or operation.

The company guarantee that their instruments will operate within 1 per cent. of their set capacity under all circumstances. They have them in use on all systems and voltages and claim to manufacture the only successful alternating current circuit breaker now on the market.

TROPENAS STEEL FOR DYNAMO MAGNETS.

THE Tropenas pneumatic steel process is a modification of the Bessemer process. It consists in decarbonizing pig iron, melted in the usual way, by means of air compressed under a light pressure. To accomplish this a special converter different in many points from the Bessemer and other similar apparatus is used.

In brief the Tropenas process differs from the other pneumatic processes in the following characteristics. The compressed air does not penetrate into the metallic bath, but acts only on its surface. Contrarily to all other similar processes which have in view the agitation, more or less, of the metallic bath, all the arrangements of the Tropenas process tend to keep the bath as quiet as possible during the operation. By so doing Tropenas avoids giving to the metallic bath any further agitation than the natural one caused by the chemical reaction going on in the bath.

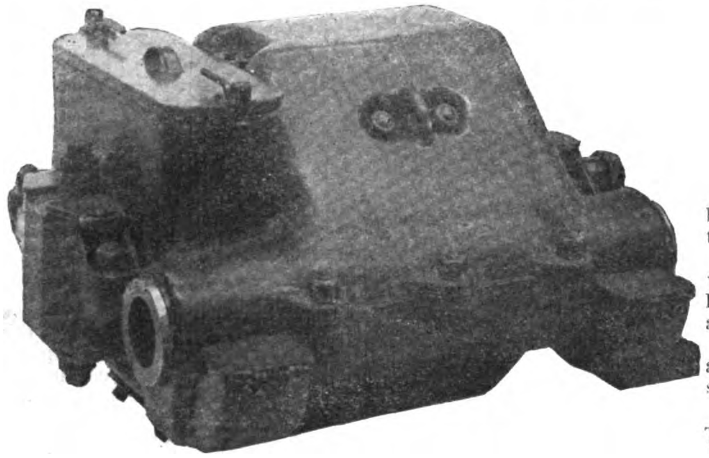
In the Bessemer operation nearly all the carbon, contained in the metal, is transformed into carbonic oxide, the proportion in volume reaching from 20 to 30 per cent. of the total quantity of the escaping gases, while in the Tropenas process, the top row of tuyeres allows of the rational burning, above the surface of the metallic bath, of all the carbonic oxide arising from the metal, thus increasing considerably the temperature of the final steel.

Tropenas steel has been found to be specially adapted for the magnets of dynamos. Tests made by Prof. J. A. Ewing on five samples, some cast at intervals of two years, show it to be of remarkable uniformity in its magnetic properties. According to Prof. Ewing, Tropenas steel may be relied on to take up, under the action of any assigned magnetizing force exceeding 30 units, an amount of magnetism which is not only absolutely very high, but is capable of being stated beforehand within narrow limits of probable variation. Prof. Ewing considers this steel an exceptionally good material for dynamo magnets. Messrs. Powell & Colné, of 27 Thames street, are the sole agents for the Tropenas steel process in the United States.

G. E.-51 RAILWAY MOTOR FOR HEAVY RAILWAY SERVICE.

Already suburban branches of steam roads and two elevated roads are operated entirely by electricity and the General Electric Company in anticipation of this new phase of electric railway work, has designed and developed, and is today prepared to furnish, every kind of apparatus for the complete electrical equipment of suburban railways now using steam. The G.E.-51 railway motor has been especially designed for high speed suburban and elevated railway work. It has a capacity of 80 horse power, rated according to the standard basis of a rise of 75 degs. Cent. above the temperature of the surrounding air after a run of one hour at rated load.

A large number of gear reduction combinations may be used to afford a wide range of speed and tractive effort. For high speed work a gear reduction of 1 to 1.74 is used, and at the present time trains of 25 to 30 tons equipped with two G.E.-51 motors having this gear reduction are operated at speeds of from 45 to 50 miles an hour with success. The G.E.-51 motor may be readily adapted to slow speed work, snow plows, freight locomotives and the like, by the use of larger gear reductions and the electric brake may be satisfactorily added to the G.E.-51 motor equipments.



G. E. 51 Railway Motor for Heavy Service.

In general appearance the G.E.-51 motor, as shown in the accompanying engraving, resembles the G.E.-1000. The field frame is two steel castings parted horizontally, but extended to the back to envelop the car axle. A large opening is provided allowing easy access to the motor for the adjustment of the brushes and the inspection of the interior. The motor, when closed, is dust-proof and water-proof. For the removal of any foreign substance that may become lodged in the bottom of the motor a handhole is provided in the bottom of the frame at the commutator end with a cover bolted on the outside.

An important and novel feature of the G.E.-51 motor appears in the bearings. The large size axle bearings are lubricated by the use of oil, and wool waste is packed in the oil reservoir underneath. The armature bearings are lubricated in like manner and all the bearings are essentially similar to those designed for steam railroad service according to Master Car Builder's specifications. A special feature of the armature bearing is the adjustment, the armature being raised and lowered by set screws at the top and bottom of the armature bearings. The range of axle diameters for which the motors may be fitted is from 4 to 5 inches. The armature construction is the standard adopted in all the G. E. motors.

PARAGON LONG BURNING ARC LAMPS.

A lamp long needed by central station people has been placed on the market by the Paragon Arc Lamp Co., 16 State street, Boston, in the form of a long-burning (100-hour) lamp for either a 6.8 or 9.6 ampere series circuit. As no resistance is used, there is in consequence no waste of energy. The lamps burn steadily throughout the entire life of the carbons, and will operate satisfactorily on any of the standard types of arc machines.

Paragon Arc Lamp.

One of the chief features of the lamp is an automatic cut-out which will do its work quickly and effectually, should the lamp from any cause receive an excess voltage, thus obviating any liability of burning out the coils.

The manufacturers are meeting with very gratifying results and look for a large business along this line during the coming season.

THE "IDEAL" AUTOMATIC INTERRUPTER FOR INDUCTION COILS.

Messrs. Willyoung & Co., of Philadelphia, have recently brought out an improved interrupter for induction coil work which they claim to be superior to other forms of automatic break.

That the scheme of this new interrupter is unique, is readily seen by inspection of Fig. 1, which shows the interrupter in diagram. The spring G is supported at its lower extremity, just as with the Apps vibrator, but is otherwise entirely free. Surrounding the spring, near the hammer-head, is a yoke H, rigidly attached to a stiff casting I, which is itself pivoted below. This casting carries the front contact point J. The back contact point K is controlled by a pair of set-screws L, while a lower adjusting screw M controls the tension of a helical spring N, itself attached to the casting I. The spring G is very stiff and, when vertical, stands entirely free of the yoke N.

In action the hammer-head is attracted by the core, but, quite otherwise than in the App's interrupter, is able to move a considerable distance and attain a very high velocity of motion before striking the yoke, and thus breaking the circuit. The magnetic pull on the hammer-head being thus released, the hammer-head flies back, partly by virtue of its own spring G and partly on account of the pull of the spring N. The contact points coming together close the circuit once more, and the core's magnetism immediately begins again to act upon the hammer-head, the motion of which, however, it can instantly stop, and the head swings on, being gradually brought to rest and its motion reversed again, striking the yoke while moving at high speed.

That the suddenness of this break is much greater than with the Apps break is evidenced by several facts. In the first place, the firing is practically nil, and when coils of 8 to 12 inch even are run with it upon a proper electromotive force, it is actually necessary often to look closely at the vibrator in order to see any sparking whatever. Furthermore, after continuous runs for thirty or forty-five minutes, or even more, there is no appreciable rise of temperature even at the contact points. A further evidence is that the same coil operated by the new vibrator, as compared with the Apps, it is claimed, requires not over one-half the current to produce results equally as good, if not better.

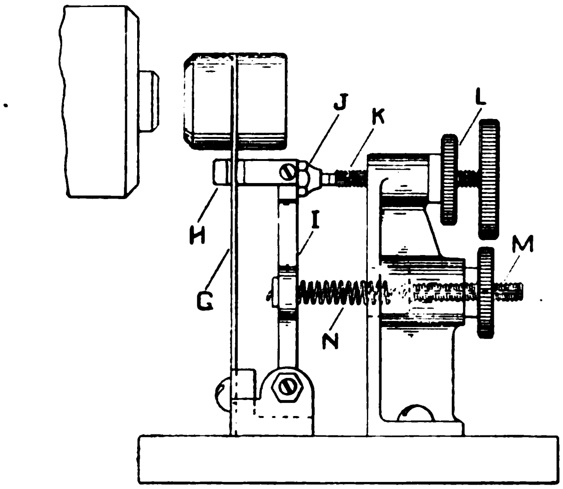


Fig. 1. - The Willyoung Interrupter.

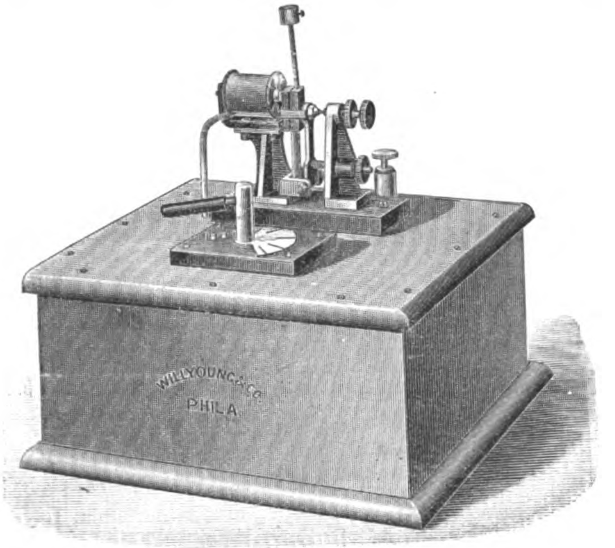

Fig. 2.—The Willyoung Interrupter.

Fig. 2 shows the "Ideal" interrupter combined with the Willyoung adjustable condenser. The "Ideal" interrupter is protected to Messrs. Willyoung & Co. by application for letters patent and is for sale, as is all Willyoung apparatus, by Mr. James G. Biddle, 910 Drexel Building, Philadelphia.

RECENT CHLORIDE ACCUMULATOR INSTALLATIONS.

The Electric Storage Battery Company has recently contracted to install a battery of chloride accumulators in the Queen's Insurance Company's new building, corner of Cedar and William streets, New York. During the day the battery will be operated as a regulator of potential, allowing the elevator and lighting services to be taken from one generator, and during the night and over holidays and Sundays, the battery will furnish all the current required by the lamps and elevators.

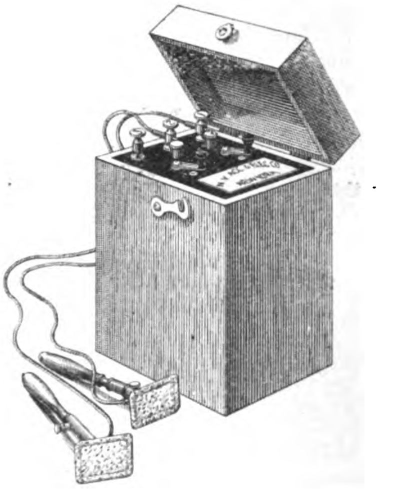
Other contracts recently closed cover batteries for supplying night lamps and elevator service in the building, being erected by Messrs. Jones Bros., Brooklyn; this plant will be operated at 240 volts throughout; a battery for lighting the casemates at Fort Wadsworth; another for use in connection with the gas engine dynamo plant to be installed in St. Paul's M. E. Church, New York; a battery for night lighting and lamp testing at the lamp works at Harrison, N. J. The Commercial Cable Company is installing a battery of chloride accumulators in its new building to be used for operating its ocean cables.

Chloride accumulators are also being installed upon the following named yachts: Marietta, Hiawatha, Althea, Hildegarde, and two other yachts which have not yet been named.

ELECTRO-MEDICAL STORAGE BATTERY.

A HANDY source of current has become a necessity to the surgeon and physician, and where patients have been taught to administer current themselves it is also important to furnish as convenient a battery as possible. The New York Accumulator & Electric Company, of 150 Nassau street, New York, has met the demand for such a source of current by designing and building the portable storage battery outfit, one form of which is illustrated in the accompanying engraving.

The outfit consists of a highly polished mahogany or oak cabinet, in which are fitted one or more cells of storage battery (of the company's manufacture), sealed in hard rubber boxes, a medical induction coil with hand or sponge electrodes and conducting cords, and the necessary connections for using either the primary or secondary current, or the two combined.



Electro Medical Storage Battery.

Some of the special features provided with these batteries are a graduated wire rheostat to regulate the strength of the primary current and a volt indicator—a low-voltage lamp—to tell when the battery needs recharging. The medical induction coil, with the necessary connections, switch device and accessories, is contained in a separate compartment, and is removable without disturbing the battery, or vice versa. The insulating parts are of polished hard rubber. The metal parts are all nickel-plated.

The outfits for physicians' use have the same general features, but are finer in the details of construction. The battery, too, is of larger capacity, so as to provide for light cautery work and for lighting a surgical lamp.

WESTINGHOUSE ALTERNATING CURRENT FAN MOTOR.

The Westinghouse Electric and Manufacturing Company has, it informs us, succeeded in constructing an alternating current fan motor for the season of 1897 that by its many advantages of construction and operation will bid fair to become the most popular fan motor of the coming season. It is of the induction type and differs somewhat from the mechanical proportions of the fan motors of recent years in being smaller and lighter. It retains the feature that was introduced in the Westinghouse fan motor of last year and which was found of great practical value, that is, "speed variable at will," which is effected by the use of a three-contact switch of simple construction located in the base of the fan motor. By means of this switch the motor may be run at full speed, at moderate speed, or it may be cut out of the circuit.

When the motor is running at full speed the breeze of air supplied is strong, steady and of wide range. When running at moderate speed, the motor successfully meets the requirements of the best desk fan, the breeze being considerably reduced and the current required to drive it being materially less. The motor is especially useful in a sick room or a bed room at night, securing effective circulation of air and operating almost without noise.

This fan motor has neither a commutator nor brushes, and weighs complete, ready for service, twenty-five pounds.

LUNDELL FAN MOTORS.

The Lundell fan motors, manufactured by the Interior Conduit and Insulation Company, of New York, are so well known that a description of them would seem almost superfluous. These machines have been sold all over the world and the name "Lundell' has become synonymous with "Highest Standard of Merit." The company has placed upon the market this season several new styles of ceiling and column apparatus and their handsome illustrated catalogue shows a varied and complete line. The "Lundell" is not a cheap affair, but is a machine well made in every particular, handsome in design and finish, and of highest obtainable efficiency. Illustrations of these fan motors are unnecessary, for the reason that the general public, as well as the trade, are thoroughly familiar with their design and appearance.

THE PIONEER ARC LAMP ABROAD.

Prof. Louis B. Marks is now on his way back from Europe, where he has been very successful in bringing the enclosed arc lamp to the notice of scientists and electric light people. The Electric Arc Light Company inform us that on Prof. Marks' return patent litigation will be vigorously prosecuted.

ADVERTISERS' HINTS

THE PHILADELPHIA ELECTRIC AND MANUFACTURING COMPANY, 2010 Jones street, Philadelphia, are advertising a clutch for which they claim perfection. It can be applied to Brush as well as T.-H. lamps. They also manufacture commutators, segments, blocks, brushes, arc cut-outs and all arc lighting supplies.

ANCHOR ELECTRIC COMPANY, 71 Federal street, Boston, say their snap flush switches are still in the lead.

FISHER & CRAMPHORN, Congress and A streets, Boston, are at all times ready to give estimates on switchboards of which they make a specialty. They also furnish station switches for low and high voltages.

MACHADO & ROLLER, 203 Broadway, New York, say the "A. E. G." incandescent lamps are "all extra good;" and suggest the trial of a barrel lot as a means of proving it.

THE KEYSTONE ELECTRIC INSTRUMENT COMPANY, of Philadelphia, have removed their New York office from 36 Dey street to the Smith building, 15 Cortlandt street.

JAMES LEFFEL & CO., Springfield, O., are building water wheels for heads of 3 to 2,000 feet. Among the installations which have attracted considerable attention is the plant of the Niagara Falls Hydraulic Power and Manufacturing Company.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, New York, ask if money is an object to electric lighting and railway companies, and if so why many of them permit thousands of dollars to escape to the atmosphere from their exhaust pipes, which might be saved by utilizing their waste steam for heating by the Holly system.

THE BRYANT ELECTRIC COMPANY are advertising sockets.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, O., call attention to their line shaft motors, direct connected and slow speed, as the latest development in power transmission for factories.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., note how the use of accumulators make possible the most modern methods of transmission and distribution.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., under the caption of "Large Westinghouse Alternators," present a list of large generators they have installed, among them being the direct connected engine type installed in 1890 in the station of the Narragansett Electric Lighting Company, described elsewhere in this issue.

THE ELECTRICAL ENGINEERING AND SUPPLY COMpany, Syracuse, N. Y., illustrate their "ad" with a cut of a double break knife switch specially adapted to switchboard work.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, say the Bryant-Cleveland arc light cut-out is the best on the market, and this is but one of the specialties in their arc light supplies stock.

THE STANLEY ELECTRIC MFG. COMPANY, Pittsfield, Mass., advertise the S. K. C. static ground detector. They are in use in many central stations, among them being that of the Narragansett Electric Lighting Company, described elsewhere in this issue.

J. G. BIDDLE, 906 Drexel building, Philadelphia, Pa., makes a specialty of central station photometers built according to the German Reichsanstalt pattern.

THE FORT WAYNE ELECTRIC CORPORATION, Fort Wayne, Ind., have no less than sixteen of their constant current 125, 2,000-candle-power arc light machines in the Narragansett Electric Lighting Company's station, Providence,, R. I. They were selected after ninety days' trial.

SHIFF, JORDAN & CO., 39 Cortlandt street, New York, remark how useless it is to have good lamps unless the carbons are also good, and suggest that by using the "Ship" brand the second condition is met.

EDWARDS & CO., 144th street and Fourth avenue, New York, show the scraping contacts on the "New York" door and window springs, which are one of their many specialties.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING CO., 15 Cortlandt street, have something to say regarding that often discussed question, "Protection." In the electrical sense, they advocate the Habirshaw insulation as protection and perfection.

THE ARMINGTON & SIMS ENGINE COMPANY, Providence, R. I., have installed over 5,000 engines which are now in successful operation.

WALKER COMPANY, Cleveland, O., calls attention to the fact that every coil in their dynamos has a safety fuse as an effective means of preventing serious delays in their operation.

PARTRICK & CARTER, Philadelphia, have made arrangements with leading supply houses throughout the country for handling their goods.

THE NEW YORK DYNAMO AND MOTOR COMPANY, 257 Broadway, New York, have 1,000 fan motors for sale at $15, and they guarantee each one.

THE RUSSELL ELECTRIC MANUFACTURING COMPANY supplied 2,000 mast arms for the lines of the Narragansett Electric Light Company, and they have had no complaints from them.

THE GARTON DANIELS ELECTRIC COMPANY, Keokuk, Ia., quote a central station man who observes that the protection afforded by their lightning arresters is equal to a paid-up insurance policy.

THE INTERIOR CONDUIT AND INSULATION COMPANY, 527 West Thirty-fourth street, New York, are ready with their 1897 styles of fans and a catalogue will be sent to those requesting it.

FABIUS HENRION, Nancy, France, publishes in his "ad" a price list of carbons for which he claims the highest reputation in the world.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., have an alternating current ceiling fan absolutely guaranteed against burning out, as well as many other advantages.

THE PARAGON ARC LAMP COMPANY, have recently brought out a 100-hour arc lamp for series circuits. The Conover-Goe Company, Monadnock Block, Chicago, are the Western agents. A card to either office will elicit full information and prices.

THE WESTERN ELECTRIC COMPANY, Chicago, manufacture a ceiling fan to consume but .6 of an ampere at 110 volts. They are ready to deliver fans for 110 or 220 volts and will furnish them upon order for 500 to 550 volts.

NEW ENGLAND NOTES

FISHER & CRAMPHORN, of Boston, have just brought out a new line of jack-knife switches for high voltage, which meets the high requirements of the local wire commissioners, and which has many improvements over the old style. These switches are made of composition metal, hard rolled copper blades and contacts, and are furnished with a spring, so that it is impossible for a switch to remain in a position where it will arc. It must either be fully closed or wide open. All users of switches would do well to inquire into their merits, as they are already having a large sale and are in demand. They have a neat, new catalogue which they will be glad to send on application.

THE BATES MACHINE COMPANY, of Boston, are meeting with great success with the Bates motor, and have already installed a large number in and around Boston, which are giving great satisfaction. So great, indeed, has been their success in New England, that they have arranged to open a branch office in New York, and have secured quarters at 136 Liberty street, New York City. Besides electric motors, the Bates Machine Company carry a full stock of power transmission machinery, including engines, boilers, pumps, shafting hangers, pulleys, etc., which enables them to furnish complete installations for either power or lighting.

THE ANCHOR ELECTRIC COMPANY, of Boston, have just issued a handsome new catalogue of electric lighting supplies, which should be found in every electrician's hands. It is of convenient size, and will be found to contain everything in the way of supplies necessary for the complete installation of an electric lighting plant. They make a specialty of Anchor snap switches, single and double pole 3 point and 4 point switches, 500-volt switches, flush switches and every other conceivable kind of switch. They also show a variety of Anchor sockets, cut-outs, rosettes, etc. The Anchor Company are steadily increasing their business and the outlook for the coming spring trade is exceptionally good.

THE RUSSELL ELECTRIC MANUFACTURING COMPANY, of Providence, R. I., are enjoying the success of years of application to the mast-arm trade, and have a number of nice orders on hand. Two thousand mast arms in the city of Providence alone, is a pretty good testimonial as to their successful operation; and Mr. Russell is to be congratulated on the success of the business with which he has been so long identified. They have some very pretty circulars to send to any one interested in this form of street lighting.

NEW YORK NOTES.

C. F. CROSELMIRE, Newark, N. J., manufacturer of platinum wire, sheets, etc., reports business satisfactory. Mr. F. A. Croselmire has just returned from an extensive trip among the electrical trade and booked some very large orders. Mr. C. F. Croselmire starts out the end of this month upon a three months' trip to the Ural Mountains, Siberia, for the purchase of crude platinum.

UHLING, STEINBART & CO., 61 Mulberry street, Newark, N. J., are putting on the market their new recording gauge in connection with their pneumatic pyrometer and gas composimeter which they guarantee to be absolutely accurate. It has the further advantage of making record on a rectilinear axis on a continuous roll of paper. The gas composimeter is a new instrument for continuously indicating and recording the percentage of CO_2 in the flue gases of boilers, thus making a perfect record of the combustion and incidentally the consumption of the coal. This firm will be pleased to give further information and prices of their apparatus on application.

STUCKY & HECK ELECTRICAL MANUFACTURING CO., Newark, N. J., are doing all the repair work on a number of electrical apparatuses damaged at the recent fire in the Newark Electric Light Company's plant. They report their factory busy also on a number of electrical specialties and railroad work.

THE FUEL ECONOMIZER COMPANY, Matteawan, N. Y., report their works busy on quite a number of orders. Among the many plants installed of recent date with their fuel economizer are: Chas. Spreckels' beet sugar refinery, at Salinas, Cal.; Anhauser-Busch Brewing Company, St. Louis, Mo.; Armour Packing Company, Kansas City, Mo.; Pfister Vogel Leather Company, Milwaukee, Wis.; Merrimac Chemical Company, Boston, Mass; J. W. Dimick, carpet manufacturer, Rifton Glen, N. Y.

WESTERN NOTES

THE McDERMID MFG. COMPANY, 205 South Canal street, Chicago, report that the demand for their battery coppers keeps steadily on the increase, and also that the prospects of good business in their other lines in the near future is very encouraging.

MR. J. E. KEELYN, of the Western Telephone Construction Company, has been in St. Paul, conferring with large Minnesota capitalists as to new telephone exchanges for that city and Minneapolis.

SALT LAKE CITY is going to buy and put up its own wires and lamps necessary for street lighting purposes, and the Utah Power Company is to supply the current and poles.

THE SHELBY ELECTRIC COMPANY, of Shelby, O., report an increasing sale of their incandescent lamps. They are running night and day and are enlarging their capacity. The Paragon Arc Lamp Company, of Boston, has taken the New England agency for their lamps. Mr. Smith, vice-president and general manager of the Shelby Company, was formerly manager of the Perkins Company, of Boston, and has had a great deal of experience in the sale of incandescent lamps.

SYRACUSE RAIL BOND.—The Metropolitan Electric Company of Chicago have taken the agency of the Syracuse rail bond. This bond is the only one on the market that utilizes the fish plate holes and requires no drilling. It is soldered fast to the rail, and the fish plate bolts reinforce the joints, making absolutely homogeneous contact during the life of the rail, and giving a surface connection between copper and rail of ten times the cross section of the bond conductors, thus making the best possible construction. The Metropolitan Electric Company have just issued circulars fully describing the rail bond.

THE CENTRAL ELECTRIC COMPANY has taken the Western agency for the Wagner alternating current ceiling fan motor. This motor is constructed on radically new lines and has many new commendable features. Notably, it is absolutely noiseless in operation and consumes 120 watts when running at normal speed of 125 revolutions per minute; is guaranteed to produce an external agitation of the atmosphere without producing the same result on the purchaser.

ELECTRIC LIGHTING

RECONSTRUCTION OF THE ALTERNATING CURRENT SYSTEM OF THE ROYAL ELECTRIC COMPANY, MONTREAL, CANADA.

BY P. G. GOSSLER.

To meet the general increasing demand for light and power supplied from central stations, it has, in many instances, been necessary to erect new generating stations or to reconstruct the existing plant, discarding the old, inefficient apparatus and substituting therefor equipment of modern design. In some of the larger cities this fact has apparently been appreciated, as recently there have been erected stations which are magnificent examples of modern generating plants, operating with the highest economy obtainable at the present time and giving evidence in their design of the highest engineering skill.

Many generating stations at present supplying a large output have attained their growth gradually, having from time to time installed additional apparatus as it was required by an increasing business and extension of territory supplied. These stations are now confronted by figures and results showing their cost of operation per unit of output to be much more than it should be, or would be, if the same output were produced by more efficient apparatus operating under modern conditions. Besides, there is generally a multiplicity and variety of apparatus, the operation of which is accompanied with danger and results in unsatisfactory service.

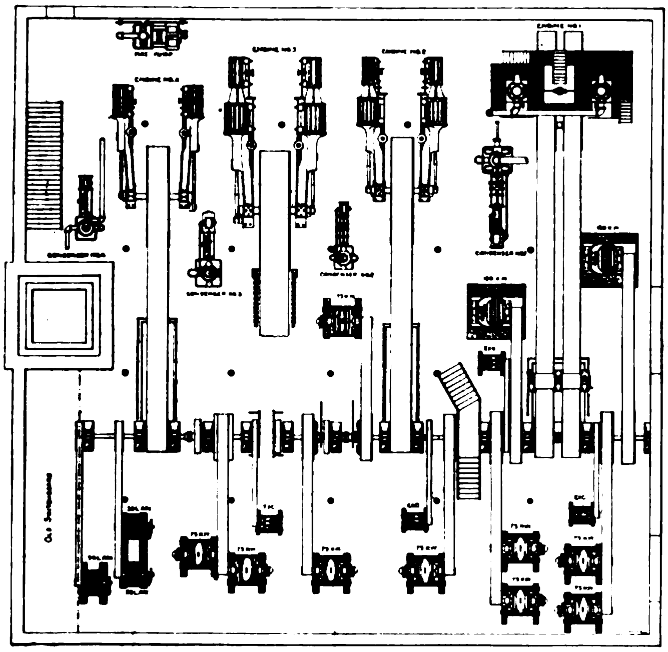

FIG. 1.—FORMER ARRANGEMENT OF MACHINERY ON GROUND FLOOR.

The necessity of giving satisfactory and uniform service, of reducing the cost of operation and of meeting the increasing demands for light and power being recognized, and the conditions being such as to permit of meeting these requirements, an investigation of the existing conditions generally results in the adopting of one of two plans. First, the building of a new generating station and equipping it with modern apparatus, utilizing the old plant for continuing the service during the course of the construction of the new one, and possibly retaining it afterwards as spare capacity; or, secondly, to reconstruct and re-equip the existing plant to conform to the aforementioned requirements.

The latter plan or reconstruction will, without doubt, be decided upon in the majority of cases, as the use of large units permits of the installation of sufficient capacity, in the same space occupied by the old apparatus, to meet future demands for a reasonable length of time.

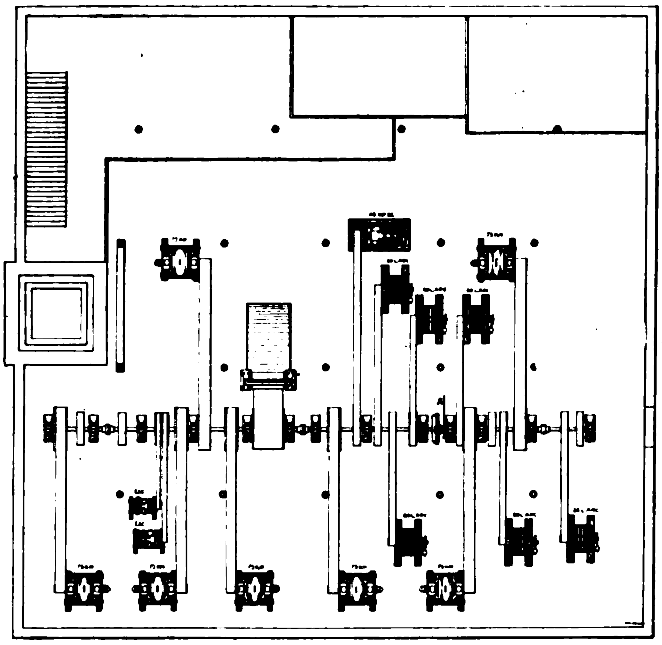

FIG. 2.—FORMER ARRANGEMENT OF MACHINERY ON FIRST FLAT.

There have been numerous descriptions published giving examples of plants erected to replace those found to be inefficient and giving unsatisfactory service. It is to be noted that, so far, these new plants with but few exceptions are direct current stations, serving light and power to congested districts and comparatively small areas; this account is of the reconstruction of an alternating current system supplying current to a large territory.

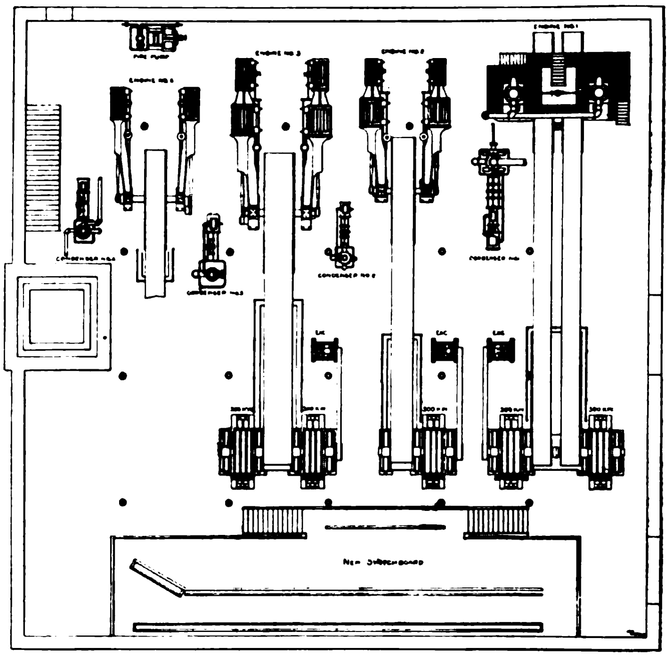

FIG. 3.—PRESENT GENERATING PLANT MASSED ON ONE FLAT.

The history of the Royal Electric Company, of Montreal,

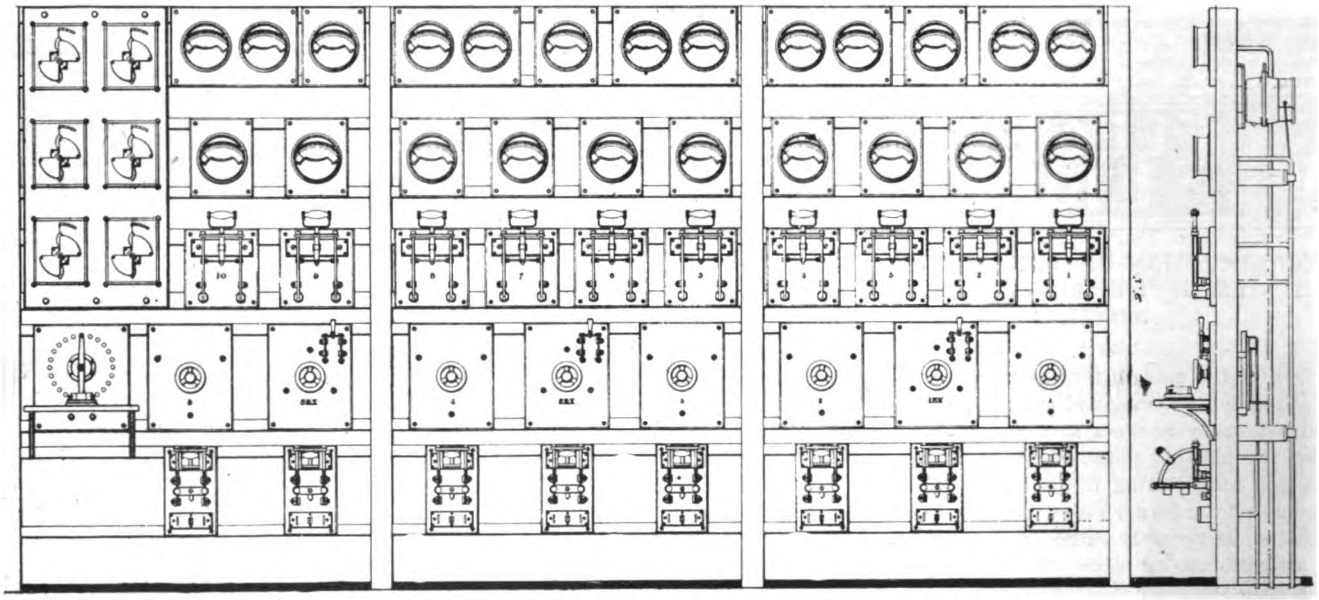

DIAGRAM NO. 4.

FIG. 4.—ARRANGEMENT OF SWITCHES, RHEOSTATS AND INSTRUMENTS ON SWITCHBOARD.

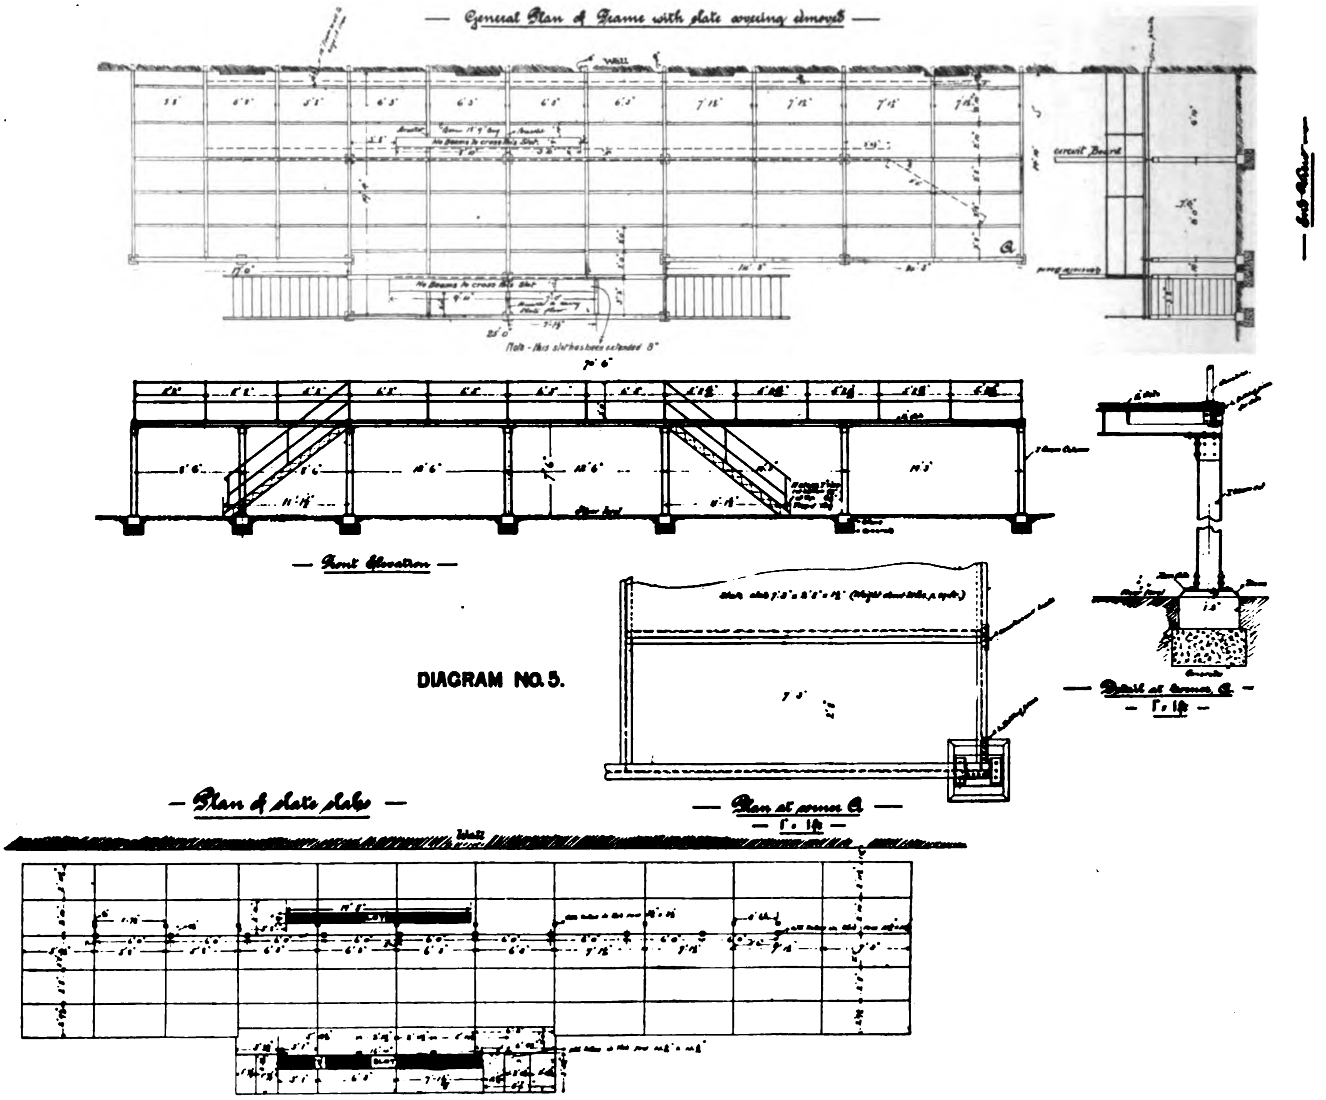

FIG. 5.—FLOOR PLAN OF SWITCHBOARD AND DETAIL OF IRON FRAME WORK SUPPORTING THE SLAB FLOOR.

and the growth of its lighting and power plants from a 12-light arc machine in 1884 to the present time, when it is serving about 65,000 incandescent lamps, 1,750 arc lamps and 750 horse power in motors, has been told before and need, therefore, not be repeated here. Early in 1896 the directors of the company, upon the recommendation of the general manager, Mr. W. H. Browne, authorized the entire reconstruction of its alternating current station and lines; this reconstruction to be carried out upon plans which would adapt the system to be served either with power from its existing steam plant or from the water power plant at Chambly, which is at present being rapidly developed.

The foresight shown in the recommendation and authorization of this wholesale reconstruction and re-equipment has been well established by results already obtained. The economy of replacing inefficient apparatus by apparatus which is the product of the highest grade of engineering, is, in this instance, no longer a possibility, but an established fact.

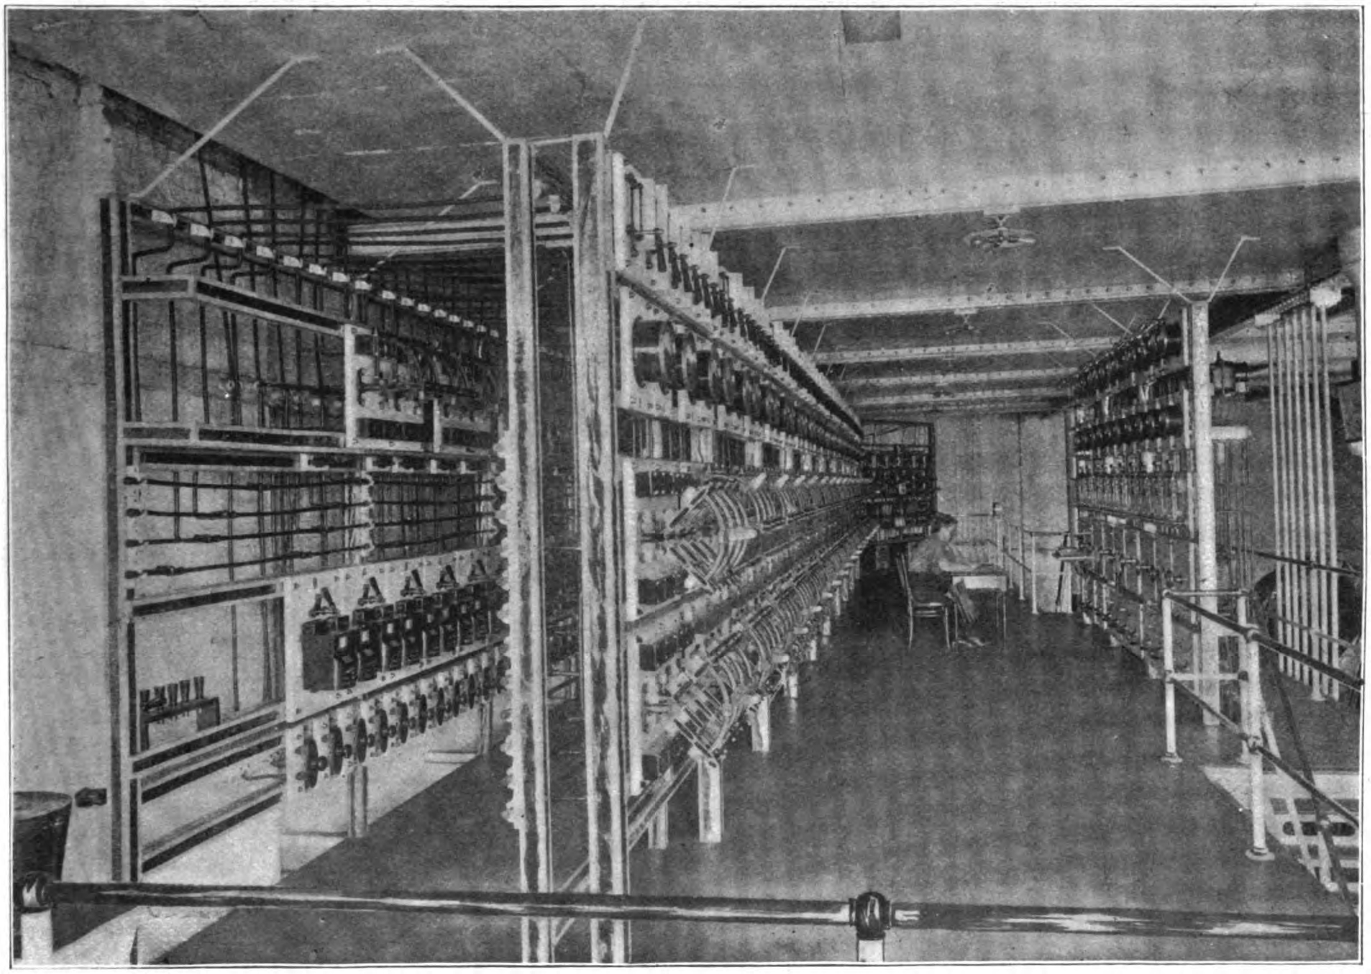

Fig. 6.—View of Circuit and Terminal Switchboards, Royal Electric Co., Montreal.

One of the two generating stations of the Royal Electric Company is devoted exclusively to supplying direct current arc service. The equipment of the second or Queen street station, for serving light from an alternating system, with a spare series arc capacity, prior to its reconstruction, consisted of 18 alternators, 6 exciters and 9 arc machines, with their numerous belts, pulleys and shafting, shown in Figs. 1 and 2, representing the apparatus on the ground and first flats. The direct current power generators and engines are located in a separate building. The upright engine, known as No. 1, shown next to Queen street, in Fig. 1, was connected by two 30-inch belts to a line shaft from which were operated four 75-kilowatt and two 150-kilowatt alternators and two exciters. Operated from the line shafting connected to No. 2 engine were three 75-kilowatt alternators and an exciter. No. 3 engine, located on the ground flat was belted by a 50-inch belt to a line shaft on the first flat, shown in Fig. 2. To this line shafting were connected seven 75-kilowatt alternators, two exciters, one 45-kilowatt, direct current generator, five 40-light and one 35-light arc machines. These latter were used only as spare capacity for the series arc system located in the East End station, and the 45-kilowatt generator as spare capacity for the direct current power system. The total capacity of the machines connected to this line shafting was much more than the capacity of the engine, consequently only part of the machines connected to No. 3 line shafting could be fully loaded at any one time. With that part of the shafting thrown out of service by the clutch shown at A, Fig. 2, there yet remained connected to the shafting in service three 40-light arc machines, which had to be up to speed whether they were required or not. To No. 4 engine were connected by line shafting two 75-kilowatt alternators and three 50-light arc machines.

It will be unnecessary to give in detail the heavy line shafting losses and the dangers and disadvantages of such an arrangement of machines as shown in Figs. 1 and 2, as they will be apparent at first sight. There was another danger which menaced the safety of the entire system—a wooden switchboard, the capacity and arrangement of which was entirely inadequate for the service required of it.

The alternators connected to the same engine were run in parallel, six operating in parallel from No. 1 engine, three from No. 2, seven from No. 3 and two from No. 4 engine. The ordinary advantages to be gained from operating in parallel were to a great extent offset by the fact of there being no clutches on individual machines. This also introduced irregularities and interruption to the service from armature burnouts. In running so many comparatively small units in parallel it was difficult to overcome the "idle" currents in the alternators, and the numerous belts and pulleys required a nicety of adjustment which was hard to maintain after synchronism had once been established.

The foregoing statements setting forth past conditions have been made to illustrate the results of a gradual growth. It is needless to state that had the present demands for light and power been foreseen, and the efficient apparatus of to-day been available, the station equipment, in all probability, would have been far different from that which necessitated its entire reconstruction.

THE OVERHEAD LINES.

The first step of this reconstruction was the rearrangement of the overhead lines. These had been divided into three routes, each taking approximately one-third of the station output. The relative positions of the wires on the poles forming these routes, were such as to cause serious fluctuations in the lights, due to mutual induction. This became so objectionable that it was necessary to operate all the circuits forming one pole line from one set of alternators running in parallel to get comparatively steady service. When the total load was too heavy to be run from one set of alternators, this condition of the pole lines necessitated the running of two or three engines underloaded, introducing a serious loss in coal consumption. The relative positions of the wires on the poles were changed to overcome this mutual induction and most satisfactory results were obtained, as after this change it was possible to operate any circuit from any engine without the slightest fluctuation resulting.

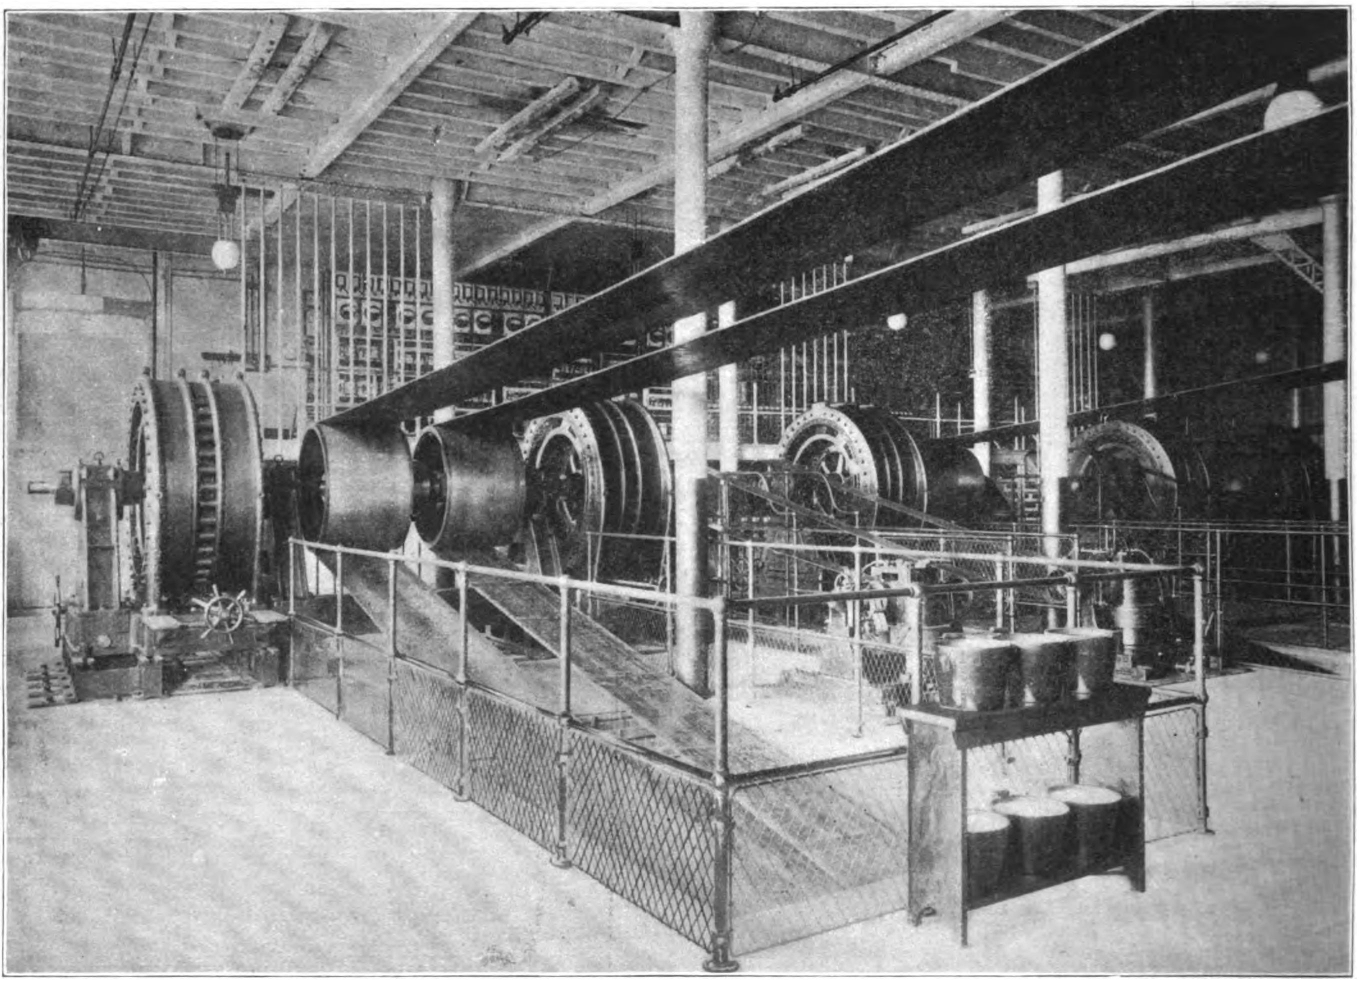

FIG. 7.—VIEW OF 300 H. P. S. K. C. TWO-PHASE GENERATORS, ROYAL ELECTRIC CO., MONTREAL.

THE TRANSFORMER SYSTEM.

The transformer system was next rearranged, the old transformers being replaced by others having close regulation and small core losses and secondary systems established wherever economical. The extent to which the latter was carried may be judged from the fact that 1,161 old transformers were replaced by 628 Stanley transformers, with a consequent reduction in leakage load of 245 amperes, representing a tremendous saving in coal.

THE GENERATING PLANT.

After getting the lines in shape attention was next directed to constructing a new switchboard and installing new alternators.

Figs. 1 and 2 show the generating plant prior to its reconstruction, occupying two flats. Fig. 3 represents the generating plant as it exists at present, occupying one instead of two flats, 18 old generators being replaced by five 300-kilowatt generators of the S. K. C. inductor type, the latter being belted directly to the engines. Also in Fig. 3 is shown the outline of the new switchboard, located overlooking the generator and engine room.

The five 300-kilowatt S. K. C., 2-phase generators were built in the manufacturing department of the Royal Electric Company. These various S. K. C. machines will be familiar to readers in the United States, as those of the Stanley Electric Manufacturing Company, of Pittsfield, Mass. To utilize the engines in their existing condition it was necessary to have the shafts of the two alternators for No. 1 engine rigidly connected, also the shafts of the alternators for No. 3 engine rigidly connected. The machines on No. 1 engine are run in parallel, as well as the two on No. 3 engine. This arrangement practically makes 600-kilowatt units on both of these engines, at the same time having the many advantages of being able to subdivide these units and have four independent alternators.

Due to the crowded condition of the station prior to reconstruction, the installing of the new machines and construction of the new switchboard, at the same time maintaining continuous service, introduced many conditions and difficulties not encountered in the erection of a new station. All of the available space being occupied by old equipment, it was not possible to first install new apparatus to replace that which was to be removed. It was therefore necessary before beginning the station reconstruction to await such time as the capacity of one of the engines could be dispensed with, with the least danger of running short of capacity in case of accident to one of the other engines. To have at all times sufficient capacity to meet the requirements and at the same time to have spare capacity for emergencies was, of course, the difficult part of the reconstruction.

Work was begun in the station by the removal of the old equipment connected to No. 2 engine and replacing it by one 300-kilowatt S. K. C. generator. The apparatus connected to No. 3 engine was next replaced by two 300-kilowatt S. K. C. generators. No. 4 engine was then reconnected to part of the line shafting on the upper flat which had previously been run from No. 3 engine. By this time the fall load was near at hand, with the new machines yet to be installed on No. 1 engine. This was an unpleasant fact confronting us at this time, and it was a great temptation to allow the old equipment to remain on No. 1 engine until spring, but the saving sure to follow the installation of new generators on this engine made it advisable to complete the reconstruction.

The load had increased to such an extent that it was not safe to be without, at least, part of the capacity of No. 1 engine at all times. To provide for this there was installed, to be run temporarily from No. 1 engine, one 300-kilowatt generator and later, owing to a heavy increase in load, one 180-kilowatt generator, both belted directly to the engine and running with very short centers to allow of the new generators, intended to be run regularly from this same engine, being placed in their proper positions, in line with the generators connected to No. 2 and No. 3 engines.

THE SWITCHBOARD.

During the time of installing the new generators there was also being constructed the new switchboard. From the diagrams it will be seen that the location of the new board brought it directly over several of the old generators, and the close quarters in which the work was done in the station will be appreciated from the statement that the iron framework, supporting the floor of the board cleared the eye bolts on top of these old machines, still operating, by only six inches.

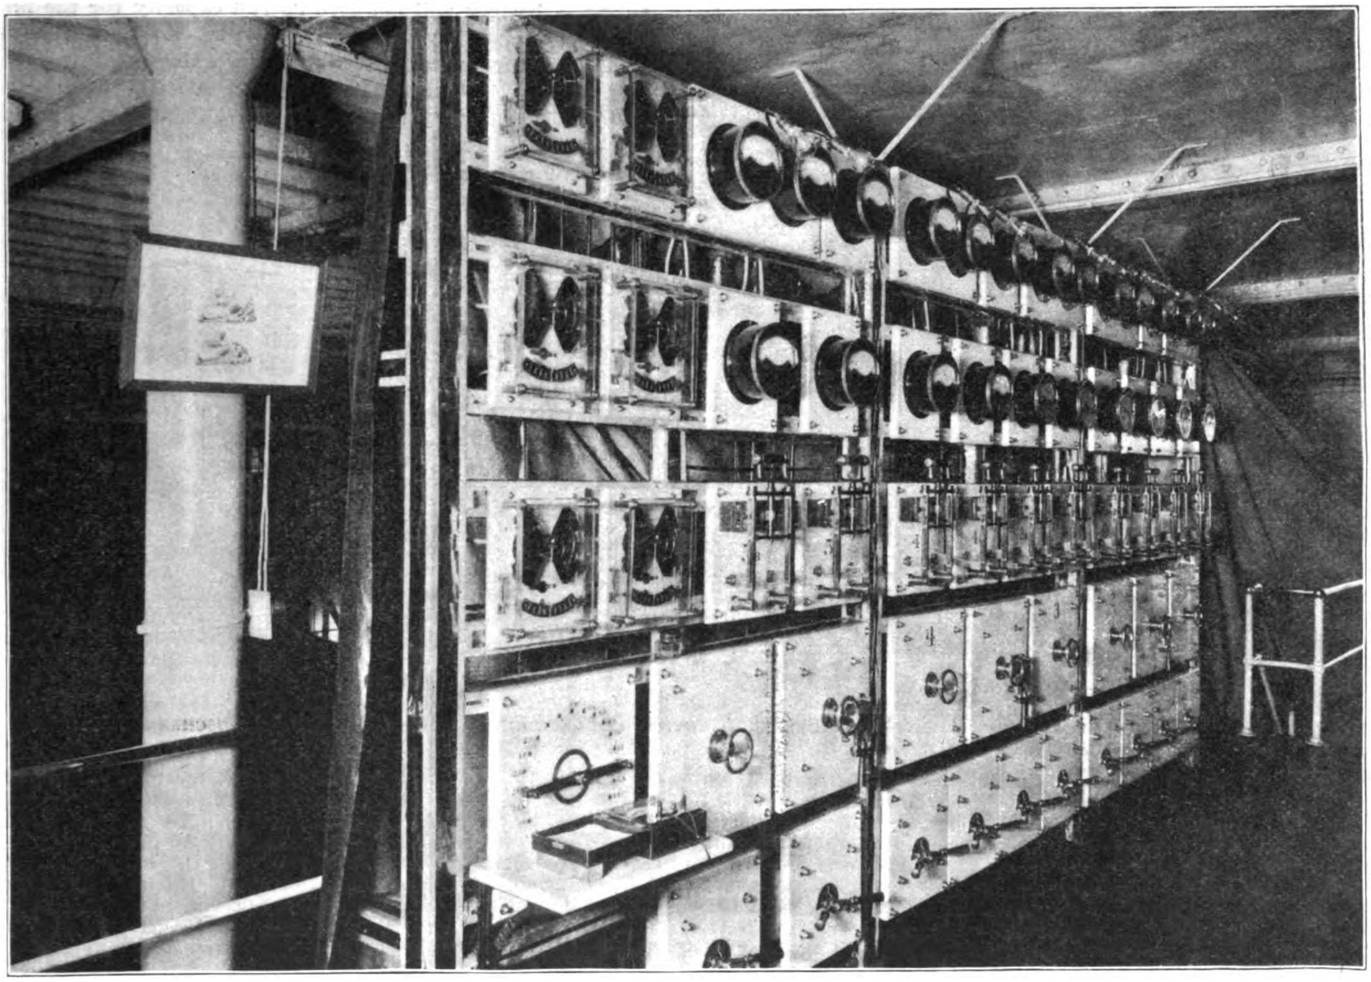

FIG. 8.—DYNAMO SWITCHBOARD, ROYAL ELECTRIC CO., MONTREAL.

The installation of the five 300-kilowatt generators was completed by the middle of October just at the beginning of the heavy winter load and the new 2-phase board was completed at about the same time.

The transferring of the service from the old to the new switchboard transformed the entire alternating system from a single to a 2-phase system. The operation of transferring the circuits from the old to the new board was of course made with all circuits alive, and while this transfer would not have been a particularly difficult operation with the service 'dead,' the transferring without any interruption to the service was a rather ticklish undertaking. It was made in the daytime within a period of ten hours without any interruption to the service or inconvenience to the customers; in fact, they were not aware at any time of the changes taking place in the station.

Fig. 8 represents the generator board and Fig. 6 the circuit board and the terminal board of the new switchboard. The board has been designed on the "universal combination" plan, by means of which there is a universal interchangeability of circuits, dynamo and exciter connections, enabling any circuit to be operated from any generator and any generator to be excited from any exciter.

Fig. 4 shows the arrangement of switches, rheostats and instruments on the generator board. The instruments on the top row, excepting the three mounted on single bases, are voltmeters, there being one for each phase of each generator; the single instruments are ammeters in the excited circuits. Below these are the generator ammeters and switches, there being one for each phase of each generator. The two lower rows show the rheostats and exciter switches.

The circuit board consists of two rows of 4-pole switches, two switches being required for each circuit. These switches are so connected that by a single throw of one switch a circuit can be connected to any generator. Above the rows of switches are mounted ammeters, one ammeter for each phase of each circuit, and above the ammeters are fuse blocks.

In the rear of the circuit board is the terminal board, on which is mounted a single row of 4-pole switches, one switch for each circuit, and an auxiliary set of bus bars, and below these a row of recording meters. By means of these auxiliary switches and bus bars any circuit panel or panels on the main circuit board can be cut "dead" and the circuit or circuits transferred to the terminal board. As the bus bars on the latter can be connected to any alternator, the terminal board duplicates to a great extent the circuit board and generator board. During the day the entire output can, if necessary, be handled from the terminal board.

Fig. 5 gives a floor plan of the switchboard and detail of iron frame work supporting the slate floor. The location of the switchboard, shown in Fig. 3, directly in front of the driving belts of the engines, is of course not desirable, but it was the only available space. There have been erected, as will be noted in the cut, Fig. 7, heavy wrought iron bars immediately in front of the belts for protecting the board in the event of a driving belt breaking.

The framework of the switchboard consists of seasoned white oak, over which is a layer of asbestos, and over this are two layers of mica, the edges of this framework being protected for mechanical purposes by fiber angles. This character of frame work for switchboards was first used in the construction of the switchboard of the United Electric Light and Power Company in New York City, and after that Company had made extensive experiments with iron and frame switchboard construction. It is practically fireproof, as well as being a good insulator, and from the severe tests during the past four years which it has withstood, there are reasons to believe that it is a very superior and satisfactory framework for switchboards.

The switches, fuses, blocks, etc., are of the standard S. K. C. type; they are independently mounted on the switchboard which permits of great interchangeability of all parts of the board.

THE RESULTS OBTAINED.

From the preceding account it will be noted that every part of the alternating system of the Royal Electric Company has been rearranged and redesigned. The lines and circuits were rearranged to overcome objectionable inductive effects and to transform them from single to double phase circuits; 1,161 old transformers were replaced by 628 new transformers with a reduction in leakage load of 245 amperes; eighteen old-style, single-phase generators with their revolving wire on the armatures, collector brushes and rings, their numerous belts, pulleys and line shaftings were replaced by five S. K. C. generators of the inductor 2-phase type, the latter being belted directly to the engines and the old wooden single-phase board was replaced by a new fireproof 2-phase board designed to distribute current for light and power from the same circuit.

All of this reconstruction has been designed and carried out on plans which adapt the system to be served either from its existing steam plant or from the Chambly water power plant. Upon the delivery of power from Chambly the five 300-kilowatt generators recently installed will be used as synchronous motors, from which will be operated the direct current arc machines.

The system affected by the above described changes operating for five months under the old conditions from October 1, 1894, to March 1, 1895, consumed 2,931 tons of coal more than was consumed in the five months from October 1, 1896, to March 1, 1897. The number of incandescent lights being 10,200 more during the latter than during the former period.

In the winter of 1894-5, it was necessary to keep in operation four engines, two each of 500 horse power, and two each of 1,000 horse power rated capacity in order to supply the demand on the station at time of heavy load. During the winter of 1896-7, one of the 500-horse-power engines was never operated and the other 500-horse-power engine was only kept turning over, doing little or no work.

Corresponding economies have been effected in the number of station employés, and oil and waste. In station maintenance—that is, of dynamos and switchboards—there has been no expense since October last, and in maintenance of transformers, nothing; whereas previously, under the old system, the maintenance account for incandescent dynamos and switchboards was several thousand dollars a year and on transformers nearly as much.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—V.

BY JOSEPH APPLETON.

[Copyright, 1897.]

INSTALLATION, CARE AND MAINTENANCE.

(Continued.)

A NEW battery will not give its full capacity for the first twenty or thirty discharges, as it takes a little time to get all the active material into proper working condition. To get a battery into first-class condition a small overcharge should be given every time for the first month; while overcharging in this manner about 25 per cent. more current should be put into the battery than has been taken out, this is done by extending the time of charge, and not by increasing the rate. In ordinary work a charge of about 10 per cent. in excess of the discharge is required to keep the battery in normal condition. In many cases, probably the majority, it is impossible to tell exactly how much current, in ampere hours, has been taken out of a battery during a discharge, therefore this cannot always be used as a guide to tell how much charge should be given.

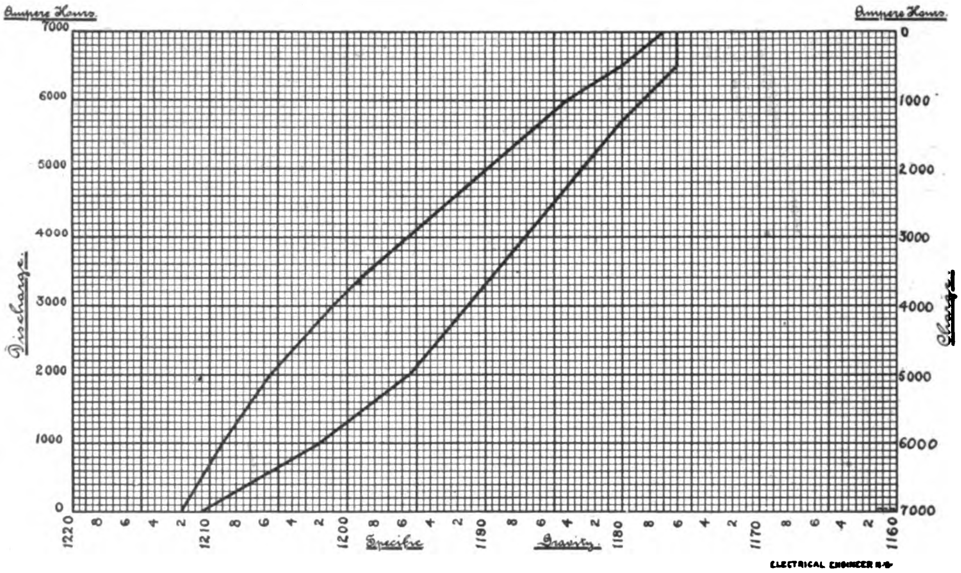

FIG. 18.—CURVE SHOWING VARIATION OF SPECIFIC GRAVITY OF ELECTROLYTE DURING CHARGE AND DISCHARGE.

In charging a battery the following points should be watched: The rate of charge is preferably kept at normal, or under, except under special conditions, or in case of emergency. Where records of discharge are kept the amount of charge required can be readily ascertained, 10 per cent. in excess of the amount taken out during discharge being sufficient. Where accurate records of the discharge are not available, it is necessary to determine the condition of a cell under charge by means of the voltage and specific gravity.

When the voltage of a cell, while charging at normal rates, reads 2.5 volts it may be considered practically, fully charged; the voltage will rise higher than this, but it is unnecessary to carry the charge further except when an occasional overcharge is given.

The specific gravity of the electrolyte is an excellent indication of the condition of a battery, but care must be taken to keep the density uniform throughout the cell. It will be found that the electrolyte at the bottom of a cell becomes denser than that at the top; this is due to the fact that during charge, when the sulphur is being returned to the electrolyte from the active material on the plates, it gravitates to the bottom of the cell, being heavier than the electrolyte.

In order to prevent this concentration of acid at the bottom of a cell, the electrolyte should be kept stirred up by means of a pump or siphon. In many plants a permanent arrangement is provided for maintaining a proper circulation of the electrolyte by means of air forced into the cell through a system of tubing connected with a small blower driven by an electric motor.

Evaporation will cause the electrolyte to fall below the level of the plates; this is detrimental and must be compensated for by the addition of water, as it is only the water which evaporates, the acid remaining in the solution. When adding water to a cell to make up for this evaporation, it should be put into the cell through a hose or funnel reaching to the bottom, otherwise the water being lighter than the acid will remain in a layer on the top.

The hydrometer measures the density of the electrolyte in the upper portion of the cell, and will give false results unless these precautions are taken, of course, the error is more noticeable in larger cells where the depth is greater. Fig. 18 shows a curve which illustrates how closely the specific gravity of the electrolyte indicates the condition of charge in a cell. This curve was taken by the writer from a large battery in one of the Edison stations, in this country.

There is certainly no better guide to the condition of a cell than the specific gravity of the electrolyte. It is possible for a cell to appear by its voltage and gassing, apparently fully charged, while in reality this is not the case, as a high internal resistance will cause a cell to give an abnormal voltage while charging, and a cell may gas freely when not fully charged, if the plates have been allowed to get into a very bad condition.

There is no action which will give a fictitious reading with the hydrometer, the density of the electrolyte being dependent on the amount of sulphur it contains, and, as previously described, it is only when the active material is fully formed or charged, that the sulphur is returned to the electrolyte; at other times it being in the plates in the form of sulphate of lead. The voltage of a cell and the specific gravity are somewhat dependent on each other, a low density electrolyte giving a lower voltage.

The best efficiency and durability is obtained from a battery when it is charged at slow rates, never exceeding the normal: this is not always the most economical method when considered from an operating point of view, especially in central stations, where often in order to meet the conditions and give the maximum efficiency to the generating plant, the battery has to be charged in four or five hours. With a modern storage battery this is quite possible, but the question of the advisability must be determined by the conditions which exist in each case, namely, whether the loss in efficiency and durability is more than made up by the economy which accrues from this plan of operation.

Occasionally during the charging of a battery, say, once in every week, the cells should be tested individually with a low reading voltmeter and hydrometer, to ascertain whether they are all of uniform voltage and specific gravity. Sometimes a cell may be found which is a little below the others in voltage. This will be more noticeable towards the end of a charge when the voltage should begin to rise rapidly, also by the low specific gravity of the electrolyte and the lack of gas given off from the plates. When a cell reads low in this way, it should be carefully overhauled and examined to see if any foreign substance has been introduced which would short-circuit the element. The color of the plates is also a good indication of the condition of a cell; the positives should be a dark brown color, free from any scale and deposit, the negatives being of a clean, gray color.

Whenever the time is available it is the best practice to reduce the charging rate towards the end of charge, when the plates commence to gas freely. Energy is being wasted when much gas is given off, and by reducing the rate until the gassing is moderated the cells can be charged nearly as quickly and with less loss of energy.

The cause of the gassing is as follows: The active material on the plates is able to absorb and utilize only a certain amount of the gas produced by the passage of the current through the electrolyte; the charging rate of a cell is fixed accordingly, so that when a cell is in a discharged condition, the active material can take up all the gas set free. As the active material becomes charged the quantity of gas it can absorb is less, consequently a portion of it is given off in bubbles.

A battery should never be discharged in ordinary work below 1.8 volts per cell when the rate is normal At high rates a lower voltage is reached before the cell is discharged to the same limit, on account of the greater fall of potential due to internal resistance; this follows the usual C^2R law.

SHOULD THE MANUFACTURE OF SCIENTIFIC APPARATUS IN THIS COUNTRY BE PROTECTED AND ENCOURAGED BY A TARIFF?

BY A. A. ZIEGLER, PRESIDENT ZIEGLER ELECTRIC CO.

THIS question may be regarded from three points of view, that of the extreme protectionist, that of the free trader, and that of the moderate or intermediate observer, who oscillates between a position favoring such a tariff as will provide sufficient revenue for the expenses of government, and one supporting duties which will afford such a measure of protection to American industry as will enable manufacturers here to compete on an even footing with importers of the foreign-made goods.

To the free trader no argument can be addressed which would be likely to change his opinion on the subject; his attitude, consistent, even if mistaken, is in favor of purchasing in the cheapest market, wherever that may be, regardless of the effect on home manufacture.

To the protectionist, on the other hand, no argument need be addressed in favor of protection as a general principle, the only matters upon which he is solicitous being, Is the industry a desirable one? does it need protection? and how much? and what, if any, exceptions should be made from the payment of duty?

The following remarks must therefore be addressed to the protectionist and the moderate man: In the first place, it may be noted that the exceptions to the rule in this connection are the most important element in the problem. The market for scientific apparatus is largely, if not almost exclusively, among colleges, schools and educational institutions of various kinds, who are entitled to import duty free under the law as it now stands, Sec. 585 of the Act of 1894, being as follows: "Philosophical and scientific apparatus, utensils, instruments and preparations, including bottles and boxes containing the same, statuary, casts of marble, bronze, alabaster or plaster of Paris; paintings, drawings and etchings, specially imported in good faith for the use of any society or institution incorporated or established for religious, philosophical, educational, scientific, or literary purposes, or for encouragement of the fine arts, and not intended for sale."

This being so, the market for apparatus of this nature would be practically restricted to those persons purchasing apparatus for their personal use, were it not for the fact that even now much apparatus can be furnished better, quicker and more cheaply by our own manufacturers than it can be obtained by importation. This condition, however, for the most part obtains in the case of the cheaper and less delicate apparatus, and where finely adjusted and expensive apparatus is required there has been an impression (not altogether unwarranted) that it was not possible to obtain such apparatus in this country, or only at a prohibitive price. Admitting this fact to be true, and with certain modifications it does approximate the truth, what is the reason for such a condition? This reason, it appears to the writer, is not far to seek, and possesses what may be considered as a reciprocating nature, in this respect—that apparatus of this class is purchased abroad for the reason that it has not been made here (or at least at as low a price), and per contra it has not been made here for the reason that it has not, with the existing demand and with the existing prices of labor, rents, taxes and other expenses, been possible to compete with the price for which such material could be imported duty free, although it might and very probably would be possible to compete with such prices, were a tariff, of say some 35 per cent ad valorem imposed on all such importations.

The remedy, therefore, suggests itself, and that is to place a specific duty by name on the various classes of apparatus falling under the general class of material now under consideration, and allow no exceptions.

This suggestion we are aware will undoubtedly be met with the usual outcry that institutions of learning should be favored in this respect by being permitted to import duty free simply because they are institutions of learning, and therefore, as such, entitled to exceptional privileges.

This argument, of the ad captandum order, is plausible and specious, but not, it is submitted, founded on principles of justice. There is no reason, it would appear, if scientific apparatus is to be deprived of the protection of the tariff, why all other materials employed in educational purposes should not be admitted duty free. The tariff on the coal used for heating the buildings, the iron and steel used in construction, and the plate glass in the windows should be relieved of the duty on their importation.

At this point we shall possibly be met with the reply that the material quoted is not such as cannot equally well be provided from our own native resources, whereas high grade scientific apparatus can only be obtained from abroad. It may not be stated quite so baldly, but that is the trend of the argument.

Now, admitting for the moment that such apparatus can at present be imported more cheaply than it can be purchased from home manufacturers, the mere raising of price should be no adverse argument in the eyes of the strict protectionist, for to him the maintenance of high prices is a consummation devoutly to be wished. To the man of more moderate views the building up of an industry which will employ skilled labor at high wages and which in course of time may have the swaddling clothes of protection removed from it (as has been practically the case with some of its elder brethren) should appeal forcibly.

It may well be that with such an infant industry as with some of our adolescent if not adult industries it will before many years be the case that we shall ask no odds from any one, and that our superior machinery, intelligence and methods will enable us to compete with the old world in price as well as in quality.

Admit, however, if you please, that this cannot be carried out in the course of a year or two, is not such a condition of affairs worth waiting for, even at the cost of some temporary augmentation of prices?

Mr. Edward Atkinson, who can hardly be considered as a protectionist, said, in an address to the New England Free Trade League, "There are many other articles still remaining on the free list which in the course of time might be fully established within the limits of our own country if the representatives should secure the same benefit which the iron masters did in the manner described for nearly a generation, ending in their complete success in establishing an American industry to the exclusion of all foreign products of like kind, at a cost to consumers already stated," etc.

And again, "Southern members rightly claim that if protection with incidental revenue is to be the policy of the country it should cover the whole country and be applied to all arts and products."

The logic of this position can hardly be disputed, but it may be urged on the other hand, as it has been with regard to the question of books, that the purpose for which they are imported should relieve them from duty. If this is a correct point of view, as before stated, to be consistent, any dutiable material whatever if used for any purpose coming under the category of "educational" should be exempted from the application of the tariff.

Books, it may be admitted, occupy a different position from apparatus; a book is not a manufactured article or raw material either. In its essential character, a book does not consist merely of the paper and binding but of the brains put into it. It is sui generis, and a particular foreign book cannot be manufactured in this country without committing either a breach of copyright law or a moral theft. At the present date any person in the United States is at liberty to write a book and print and sell it without competition from abroad on that book. Every book is different from every other book, but this is not the case with apparatus, where the essential differences are much less.

The eleemosynary attitude with regard to public education is, we think, a weak one. Education is a good thing, so is the protection of the growing industries of the country, or the affording of temporary assistance to industries of value which have a capacity of growth within them, and the protection of American industries is now the policy of the country and one to which the administration is fully committed.

This particular industry, moreover, is not one to invite the immigration of hordes of wretched Huns, Poles, Armenians and Italians to receive from 50 to 75 cents a day, but involves skill and intelligence, and tends in every way to raise the standard of American industry, and as a necessary consequence the standard of wages also.

The solicitude displayed by our legislators in the past for the interests of labor and high wages would seem, if we may judge by the localities where labor is concentrated, to have fallen short of its ostensible purpose of raising the condition of the American workingman to some fancied height of poetic refinement and exaltation. A stroll through the districts inhabited by the working people of New York, Boston, Lowell, Fall River, Chicago, Pittsburg, Cleveland, or the mining towns of Pennsylvania, makes us wonder whither the profits of protection have vanished.

Now, here, however, is an industry which cannot be carried on by the offscourings of less fortunate countries, but which will call for the highest efforts of American skill and ingenuity. Fine mechanical work and intelligence will be essentials and these will command good pay, and furnish increased material for taxation.

It is probable that protection such as here indicated will not result in more than a temporary increase of price, but that in the course of a few years better apparatus can be produced in this country at no higher prices than those for which imported goods can be obtained. Without some such protection, however, the industry will not and cannot advance, so large a proportion of the available market being exempt, by the provisions now proposed, from any tariff.

At the risk of repetition, it may be asked why an industry such as that of the manufacture of scientific and electrical instruments should be singled out for destruction. If free trade should prevail that industry would have to take its chances in the general debacle, but so long as agriculture is no longer recognized as the main stay of the country and manufactures assume its place, and so long as the declared and preferred policy of the administration is "protection" as distinguished from "tariff for revenue"—only or mainly—it is difficult to perceive the ground for the exemption, except on the plea that the public institutions of learning are charities to be partially supported at the expense of a particular trade.

That we are not stating the position of the protectionist too strongly is, we think, shown by the following words of Congressman Walker, of Massachusetts: "We must take care of our own country and our own workingmen, and shut off by protective duties whatever might come in here that would deprive any of our people of the opportunity of supplying the needs of their own countrymen. * * * Every member from New England takes this view when he wants to get elected and when he wants to get a schedule into a tariff bill for any industry in his own district. Such a man makes a mistake when he denounces a rate that is necessary for the constituents of some other Congressman. If we are not willing to make this protective policy universal * * * we shall be forced to abandon the entire system and substitute for it the vicious free trade policy of Great Britain."

Whether or no the policy of protection is a good one is a large question, not to be discussed here, but since the elections of last year, is not open to revision for at least four years. We do not say "Protect us at the expense of all other industries," but we do say, "Protect all industries," and do not select us as the one industry to be left "naked to its enemies."

ELECTRIC HEATERS IN THE GREAT NIAGARA POWER HOUSE.

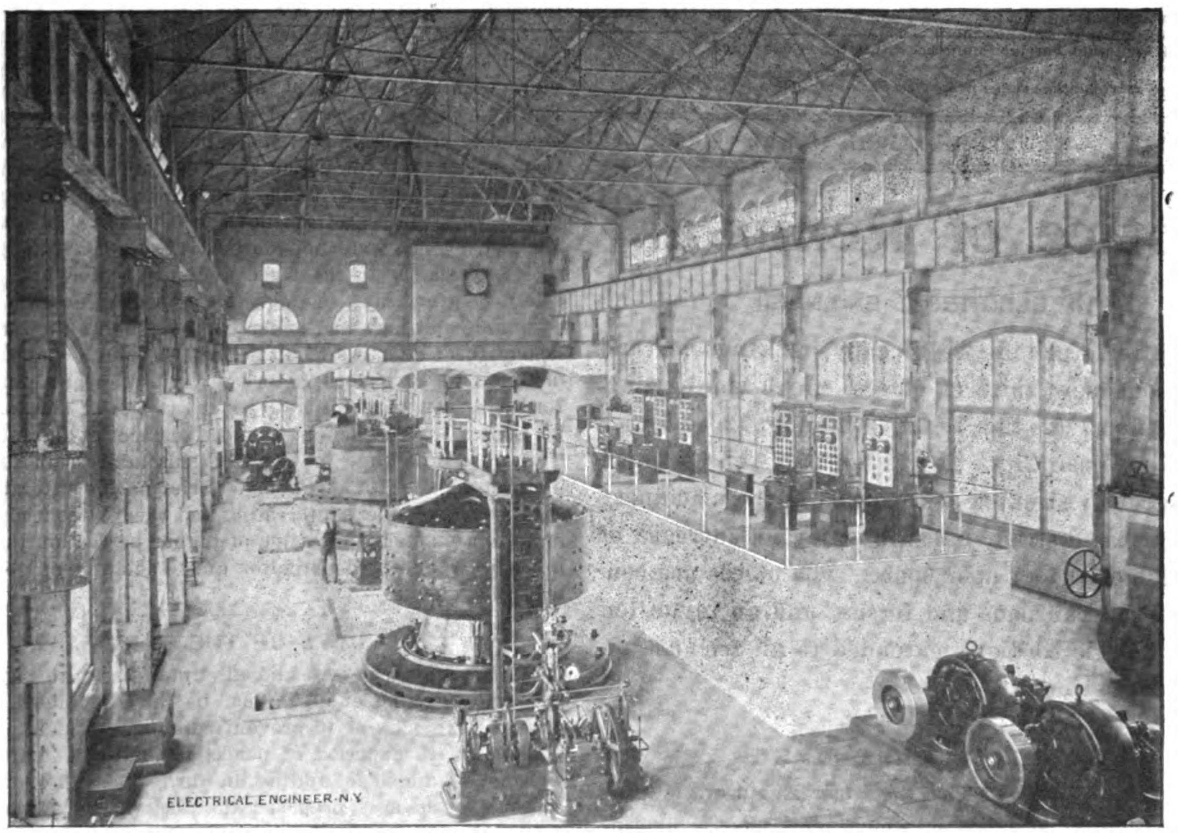
BY ORRIN E. DUNLAP.

THE central power station of the Niagara Falls Power Company at Niagara Falls is probably the largest building in the United States, if not in the world, that is heated entirely by electricity. Despite the large proportions of this structure, no heat other than electricity is employed to make it comfortable during the cold winter months. The present dimensions of the power house are, length, 195 feet; width, 60 feet, and height about 50 feet. It is of the Moorish style of architecture, and built of Queenston, Ont., limestone. The wheel-pit of the power company is being enlarged, and the power house is to be extended to cover it, but when these costly improvements are completed, electricity will still be employed to heat the building. However, the facts as given below relate to the building as it exists to-day.

The fact that the power house is divided into the dynamo room and the office quarters makes necessary the use of two kinds of heaters, one style being used in the office portion of the building, and the other in the dynamo room. All the heaters in the office portion of the building are on a secondary 100-volt circuit, which circuit is fed through converters which reduce the voltage from 2,000 to 100. The use of a high potential circuit through the offices would necessarily entail danger, and it is for this reason the low voltage was adopted. The office section is two stories in height, and in it there is about 175 horse power in heaters. These heaters are of the "American" pattern, but they are seldom all in service at the same time. Quite naturally, it depends largely upon the weather conditions as to the amount of heat necessary to make the rooms comfortable. The current devoted to heating the offices is taken from the primary of the circuit which feeds the street railways about the city of Niagara Falls. In the office occupied by Paul M. Lincoln, who is the electrical superintendent of the Niagara Falls Power Company, there are two 7-horse-power heaters, or a total of 14 horse power in this one room, which is about 20 by 15, by 9 or 10 feet high. In very cold weather it requires the service of both heaters to make the room comfortable.

In the dynamo room, which is quite spacious, the heaters employed are of an entirely different pattern than those in use in the office portion of the building. They were designed by Mr. Paul M. Lincoln and made by Dobbie, Stuart & Co., of Niagara Falls. Instead of being placed on the floor, they are fastened on the wall of the room about 15 feet above the floor. This method of placing them was adopted, partly because of the additional safety and also because it serves nicely in distributing the heat from them. In all there are 15 of these heaters in the dynamo room, placed in circuits of five each, and each circuit is capable of taking up about 200 horse-power, but it never yet has been found necessary to put all three circuits in service, two of them answering every purpose in the very coldest weather. The current used for heating purposes in the dynamo room is taken from the bus bars, and carried on No. 4 rubber covered wire. As this current is taken direct from the 2,200 volt circuit, and as each heater takes up about 40 horse power, it is apparent that to install converters to convert this power down to 100 volts, the voltage used in the office portion of the building, would be quite expensive.

All the heaters in the dynamo room are of very simple construction. They are made of two circular rolled iron plates which are about an eighth of an inch thick and 24 inches in diameter. Bolts hold these plates about four feet apart, one above the other. In each plate there are 28 holes, the diameter of each hole being about half an inch. Each of these holes contains a porcelain insulator having a large head, and through these insulators No. 6 wire is strung. In all there are 38 coils, and each coil is about an inch and a half in diameter, the distance between convolutions being about twice the diameter of the wire. The latter is such that the resistance of the heaters will take about 65 amperes at 440 volts, so that each five heaters in series will consume 65 amperes at 2,200 volts.



Electric Heaters in the Great Power House at Niagara Falls.—Heaters Suspended Around the Walls.

In heating the dynamo room and the office portion of the power house, the maximum amount of power used is about 420 or 430 horse power. It must be taken into consideration, however, that this is not taking into account the heat from the dynamos, which is an important factor so far as the dynamo room is concerned. Three dynamos, each of 5,000 horse power capacity, are now in use in the dynamo room, but, as a general thing, only two of the machines are operated at the same time. If each of the dynamos were run so as to generate 4,000 horse power instead of at its full capacity, and 3 per cent. of this power was lost in heat, which is a fair estimate, each of the two dynamos would contribute 120 horse power toward heating the dynamo room, or from the two machines 240 horse power in heat would be the result. By adding this 240 horse-power to the amount of power consumed by the heaters, it will be seen that nearly 700 horse power is consumed in heat in the building.

The Niagara Falls Power Company have found their electric heating service very comfortable, but this does not denote that electricity will yet come into general use for heating purposes. The company are fortunate in having a large amount of cheap power, but despite this fact the electrical heating of their power house is quite a luxury, and one which few people can afford.

HE LOOKED AT EMMA.

In the suit of Clara Pfeffer, by her guardian, ad litem, Leopold Pfeffer, against the Nassau Electric Railroad Company, to recover $10,000 for the loss of two toes, the jury found a verdict for the defendant. According to Mr. S. S. Whitehouse, counsel for the plaintiff, the motorman, Christian Doertem, was paying attentions to Emma Steckler, who on the day the plaintiff was injured, was visiting her aunt, Mrs. Antoinette Froelich, at No. 107 Johnson avenue, in front of which the accident happened. Counsel said that the motorman was turning to look at Emma, who was at her aunt's window, when Clara ran across the street, and that he was consequently not able to stop the car before it hurt the child. Mrs. Froelich testified that the motorman did turn his head, but Emma testified that he did not.—Brooklyn "Citizen."

FEATHER BED NO PROTECTION.

The belief that lightning will not strike a feather bed was shown to be mistaken by an incident of the electric storm of Saturday. A bolt struck a chimney on the house of Charles Steates, who lives on the Deerfield road. Part of it jumped to the house of Bernard Huss and tore off the conductor pipe. The other part went down the chimney, ripped the plaster and paper from a bedroom, and then struck a feather bed. The bed was torn and the feathers scattered about the room.—Utica (N. Y.) "Herald."

"CONCISENESS."—A reader in the South says: "I am personally a great admirer of The Electrical Engineer, and have always considered it an admirable publication. It has been a great assistance to me in my professional work. What strikes me most is its conciseness."

Vol. XXIII. NEW YORK, APRIL 14, 1897. No. 467.

Notice of Removal.

THE ELECTRICAL ENGINEER

on and after April 14 will occupy its handsome and commodious new suite of offices, entire south wing, eleventh floor, of the Beard Building, 120 Liberty street, New York City. It will not only thus be most advantageously situated at the heart of the machinery and electrical district, but will enjoy an increase of several hundred feet floor space. The offices are convenient to all railroads and ferries, and an invitation to visit them is cordially extended to all friends and patrons of the journal.

RECONSTRUCTING OLD PLANTS.

IN last week's issue of The Electrical Engineer, in commenting on the situation in which many electric lighting companies found themselves to-day it was pointed out that entire rebuilding, or extensive improvements in machinery and auxiliary apparatus, could alone bring them up to date and place them in a position to meet the present demands of the public both as regards quality of service and as to rates. To reconstruct an old station is evidently more difficult than to start in afresh from the foundations up; but in nine cases out of ten, financial considerations make it the only feasible method of attaining the desired end. How to carry out such a plan without interrupting the service is usually a serious problem and requires much finesse. Probably as representative a piece of work of this kind as has been carried out in recent years is the reconstruction of the Royal Electric Company's alternating current plant at Montreal, so well described elsewhere in this issue by the company's electrical engineer, Mr. P. G. Gossler. While the actual methods employed in this delicate engineering operation are of great value in themselves, the results in dollars and cents will perhaps appeal still more strongly to those having in charge the financial management of central stations. To put over 10,000 lights additional on the circuits and shut down 1,000 horse power in engines at the same time is an achievement which is deserving of more than passing notice; and when to this is added a considerable reduction in the cost of dynamo and transformer maintenance, dynamo attendance, oil, etc., the benefits due to the change make a superb showing. We congratulate Mr. W. H. Browne, the able general manager of the Royal Electric Company, and his technical staff on their brilliant feat, and believe that their work will not fail to have due influence on similarly situated companies this side of the border.

MR. TESLA ON ROENTGEN RAYS.

LAST week Mr. Tesla gave some of the results of his experiments in the domain of Röntgen rays, before the New York Academy of Sciences, and showed some of his latest types of high frequency generators. Mr. Tesla still adheres to his original view that the Röntgen effects are due to the action of molecules projected from the tube at high velocities, but we must confess our inability to reconcile this view with the results of his experiments in deflecting the Röntgen rays by means of a magnet, unless we assume the molecules charged and at the same time endowed with a vortical motion, a point which Mr. Tesla did not elaborate on. It is so rarely that Mr. Tesla appears on the lecture platform that it is to be regretted that the conditions surrounding his last appearance were not more favorable. It was hardly fair to Mr. Tesla, or to the large audience which had assembled solely to greet him, to delay his appearance until two other estimable speakers had taken up the time of the audience for nearly three-quarters of an hour. The result was that it was close on to 10 o'clock before Mr. Tesla began, and he was forced to conclude his address in its initial stages. It is to be hoped, for the benefit of the science at large that Mr. Tesla will find time to write out his address in full for the Transactions of the Academy. Brief as his utterances were, they were extremely interesting and they evidenced a mellowing and a mastery indicative of higher perfection than ever of his powers as an investigator and elucidator of obscure natural phenomena.

VIEWS OF THE TARIFF.

THIS country at any and all times ought to pay its way, and revenue enough must be raised to meet legitimate national expenses or to prevent running into debt. For some years past, in a period of peace, the national debt has been enormously added to, and as the tariff was a low one in some respects, it is now proposed to raise the tariff, achieving a double purpose, namely, obtaining an adequate income and insuring a degree of protection to various industries. We publish this week two views of the situation, and a third has been brought to our attention, namely, that of the leather men, headed by a Republican, ex-Mayor Schieren, of Brooklyn, who want hides to come in free as a large and growing export trade depends upon that condition. Our central station friend buys his imported carbons because he cannot get their equal here. Mr. Ziegler believes that scientific apparatus should be protected so that its production may be encouraged, and the foreign goods kept out. Thus it goes, all along the line, but there are obviously one or two facts to which all the others must be brought into harmony. The first is the necessity of sufficient national revenue, and its raising by tariffs and excises. The next is the possibility that a tariff may be so high as to be prohibitory and thus cut the revenue down. The third is that export trade has had great expansion and is based on ability to manufacture cheaply with raw material at low prices. If from these considerations, we drew the inference that a moderate tariff is in reality the need of the hour, we might not be very far in the wrong. But probably some of our readers may regard that as a personal view of the matter, and would remind us of Gen. Hancock's remark that the tariff was a local issue.

LETTERS TO THE EDITOR

ARC CARBONS AND THE NEW TARIFF.

I BEG leave to call the attention of your readers to that part of the Dingley tariff bill which provides for a change of duty on imported carbons and would thank you to give this letter publicity in your valuable paper.

Under the McKinley bill the rate of imported carbons was 20 per cent., under the Wilson bill the rate was increased to 30 per cent. The Dingley bill, now under consideration, provides for a still further increase of 20 per cent., thus bringing up the rate to 50 per cent.

While I am strongly in favor of a protective tariff, I cannot but see a gross injustice to the users of imported carbons in imposing such a ridiculously high tariff on goods that I am pretty well convinced cannot be made in this country.

The question naturally arises, who will be the gainer and who the loser by this proceeding? Will the American carbon manufacturers profit by it? No, they will not. The quality of carbons manufactured in this country is not sufficiently good to take the place of an imported carbon, and this fact is not due to the lack of proficiency in the art of manufacturing them, but to the lack of certain materials which form part of imported carbons, and which cannot be gotten in this country. It is immaterial to the European manufacturers what rate of duty they have to pay. If the new tariff goes into effect they will simply raise their prices, as some have already announced, and will, by no means, be the loser in doing so. It is the electrical fraternity that will have to suffer for this. The users of imported carbons cannot do without them, and consequently, will have to pay the increased prices. Do you think any one would willingly pay about $15 for a certain size of imported carbons, while he can get the same size of domestic carbons at $5, if he could use the latter?

The above figures prove sufficiently that American manufacturers do not need more protection than they have at present, and the importer cannot get anywhere near their prices to provide revenue for the government. I think it hardly necessary to tax thus severely a whole industry, which, in my opinion, should unite to oppose this measure.

A CENTRAL STATION MAN.

New York City, April 7, 1897.

PROF. ANTHONY'S METHOD OF MOTOR REGULATION.

IN your issue of March 31, I see that Mr. Blood returns to the attack of my method of motor speed control with the following statement, referring to my communication appearing in your issue of Feb. 10: "These remarks show that the description given in the original article was somewhat misleading. In that article (in The Electrical Engineer of Dec. 16, 1896), reference is made to the machine as a multipolar machine. This is absolutely a misnomer, since Prof. Anthony's scheme, as he now explains it, requires a bipolar machine."

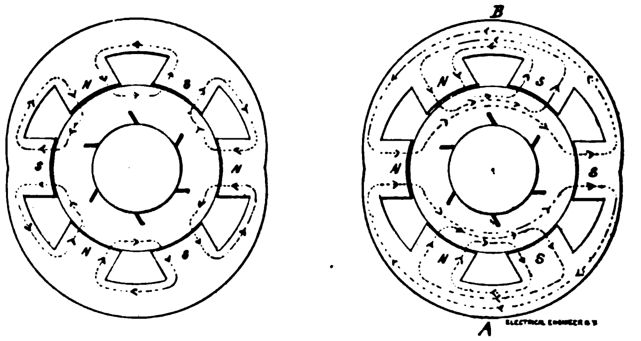
Mr. Blood is "absolutely" in error. In my communication I said: "Mine requires a multipolar armature winding of the two-path or "series" type. Any one familiar with the construction of multipolar generators or motors ought to know what kind that means, and that it is not a winding adapted to a bipolar machine. Furthermore, none but a genuine multipolar machine could work as I stated in that communication mine works.

But to be more explicit, the original experiments were performed upon a regular six-pole machine, having a drum armature whose coils embraced one-sixth of the circumference, and were connected, as is well understood, for a two path, six-pole winding. Six sets of brushes were used at intervals of 60 degs. around the commutator. These were connected three in multiple as is usual in six-pole machines. Two brushes 180 degs. apart might have been used alone on either of the three diameters of commutation. Or two brushes 60 degs. apart might have been used at either of the six pairs of commutation points. Or four brushes might have been used, omitting the two most inconvenient of access. All these arrangements were actually tried. In any case, whatever the arrangement, no change was made in the brushes used or in their connections, when the field was manipulated for changing the speed.

Fig. 1 represents the field excited as in the normal multipolar working of the machine, the pole pieces being alternately north and south. When so excited the motor made about 500 r. p. m. Fig. 2 represents the magnetization with the poles on the horizontal diameter reversed, giving three north poles on one side, and three south poles on the other side of the vertical diameter. Excited in this way the motor made 1,600 revolutions. That it made more than 1,500 was due to the fact that the field casting used was designed for a regular six-pole machine and had not sufficient sectional area to carry the magnetic flux necessary for the full field strength.

From an inspection of Fig. 2 it is plain that in a machine designed especially for this method of speed control the yoke should be considerably thickened in the regions A and B. The draughtsman has essayed to show this construction in these figures. It is plain also that the armature core should have a greater cross-section than for a regular six-pole machine.

Mr. Blood may say that Fig. 2 is a bipolar machine, but he must remember that the armature is a multipolar armature, and if he will give the matter a little thought he will see that for a bipolar machine Fig. 2 would give the slow speed and Fig. 1 the high speed, while with my method, the opposite is true, as I stated in my communication which he criticises. I consider that my method possesses great advantages over the other, but I do not care to go into that here, neither do I feel warranted in further encroaching upon your space for the discussion of the originality of my invention. Since Mr. Blood has called this in queston I will add here that none of the patents he has cited describe my method of speed control.



FIGS. 1 AND 2. PROF. ANTHONY'S METHOD OF MOTOR REGULATION.

WM. A. ANTHONY.

New York City, April 10, 1897.

AN EARLY SPRAGUE ELECTRIC RAILWAY COACH.

The description of the experiments made with a motor car pulling four standard coaches at the works of the General Electric Company recently, which appeared in your last issue, omits a somewhat important point of historical interest.

The car used was one made for the Sprague Electric Railway and Motor Company in 1887, about a year before the Richmond trolley road was put into operation. It was built by the Gilbert Car Manufacturing Company at Green Island, near Troy, was a full-sized car body, and was provided with compartments at each end so that it could be used by smokers, which is the practice on the motor cars of the Metropolitan Railroad in Chicago to-day. It was designed as an experimental motor car to pull a full-sized elevated train. It had two trucks, with 42-inch Krupp steel wheels, and each axle was to be driven by a duplex motor of 75 horse-power capacity with single gear reduction, thus making an aggregate capacity of 300 horse power.

The motors were partly constructed in the old works of the Sprague Electric Railway and Motor Company on West Thirtieth street, New York, but they were never completed, the Richmond road and the active development of the trolley system proving of more immediate importance.

The car lay in the works of the Gilbert Manufacturing Company for a number of years, and now, equipped with the heavier type of railway motors, curious to note four in number, with single gear reduction, and of almost identically the same capacity as originally projected, is put to service in experimental work on identically the same projected loads, ten years after it was built. CHAS. M. SPRAGUE.

New York City, April 9, 1897.

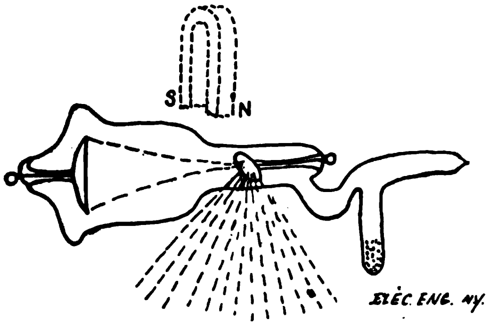
ROENTGEN RAY BURNS.

BY PROF. ELIHU THOMSON.

THE cause of the injury to the skin which follows an exposure to a source of Röntgen rays is still a subject for discussion. It is known that a comparatively short exposure at sufficiently small distances from the source will produce the effect. It has been claimed by some that Röntgen rays do not produce the mischief, but that the effect is essentially electro-static. Others have expressed the opinion that ozone and other substances present in the neighborhood of the excited tube are the real causes of the injury.

It has seemed desirable to set at rest, by experiment, these doubtful theories. The very peculiar nature of the injury itself, its course of development, the accidental circumstances under which it has occurred, have all tended to negative any theory except that which regards rays from the tube as the true cause. These rays might be either Röntgen rays, or rays so closely analogous as to be with difficulty distinguished therefrom.

The first effect after exposure is a slight reddening of the skin which is made more easily discernible by a little friction over the spot affected. This lasts two, three or more days and tends to fade. In the writer's experience, at the end of a week there has been an almost complete absence of any noticeable effect on the skin. On the ninth day, however, the affected part was found to redden, and this increased for a few days until blistering and sloughing took place with slow and tedious healing. These effects were noted in the case of the exposure of the little finger of the left hand and are at present writing in progress upon a portion of the third finger of the same hand, in consequence of an exposure for only twelve minutes to the rays from a special tube. This tube was made for the purpose of obtaining strong effects by lessening the working distance from the bombarded spot on the platinum, which is the source of the rays.



PROF. THOMSON'S X-RAY TUBE FOR POWERFUL EFFECTS.

The accompanying sketch shows the general form of the tube. It is narrowed around the platinum anode and the glass is also made thin around the same. It is thus possible to get the finger, the fluorescent screen, or the photographic film, very close to the bombarded spot on the platinum anode. The distance need be not over one-half an inch as a minimum. By the use of a magnet the spot on the platinum could be shifted so as to be very close to the glass and upon the edge of the platinum sheet. The intensity of the radiation per unit of surface was increased thereby, according to the law of inverse squares, which seems to hold in this case. This use of the magnet is indicated in dotted lines and is very convenient for directing the cathode rays upon any part of the platinum anode; which anode might in fact be faced with a variety of different substances, or have its surface differently formed, or curved at places while the cathode beam could be directed first to one part and then to another and the effects noted. If a platinum anode has been perforated by the beam at one point the tube is still useful, for a slight effect of the magnet puts the beam upon a new surface. Many a good tube may thus be made to do service even after several holes have been melted through the platinum sheet.

With such a source of rays as the tube shown it was easy to try an experiment the result of which seems to the writer to leave no doubt of the fact that Röntgen rays, or rays of the same general characteristics, do actually cause the burns and injury which may follow prolonged exposures to the Röntgen radiation. The left hand was covered with a lead sheet of over 1-16 inch in thickness and an oblong hole of about three-fourths of an inch long and about five-sixteenths inch wide, cut through it at the part just over the third finger between the first and second joint. This limited the passage of rays to the part of the finger under the opening.

But around the finger and under the middle of the opening was placed a strip of heavy tinfoil about 3-16 inch wide. This divided the exposed area into two parts. One of these parts in turn was covered with two layers of thin aluminum leaf gummed to the finger. Thus there were, in fact, three spots on the finger within the opening, one covered with aluminum foil or leaf, another with heavy tinfoil, and the third left entirely bare. The opening in the lead sheet was brought close to the platinum anode, so that the finger was about ⅝ inch distant from the bombarded spot.

The exposure was for a period of twelve minutes, which it was thought would be sufficient. The result at first was two faintly reddened spots, one having the outline of the part under the opening in the lead shield covered by the aluminum foil, and corresponding thereto, and the other corresponding to the bare spot. Under the tinfoil strip there was no action. These reddened spots, though scarcely visible, could be developed by slight friction, but gradually faded until, at the end of a week, from the time of exposure, they were with great difficulty distinguishable from the rest of the skin, even after the spot was rubbed. On the ninth day, however, they returned and the spots became painful and a little swollen. This has continued to increase and will probably end in blistering, sloughing and final healing. The part covered by the tinfoil is sharply marked from the others in being entirely unaffected. The effect produced through the aluminum leaf is about the same as on the bare spot, showing that thin aluminum does not stop the rays which produce harm.

It is needless to say that the effect is proved by the experiment to be neither electro-static, nor ozonic, but merely a result of certain rays reaching the skin surface, and such rays are probably those of the Röntgen rays not readily absorbed. According to the law of inverse squares an exposure of 12 minutes at ⅝ inch distance would require, at 10 inches distance, for equal effects, about 50 hours, or over two days. There is, then, no occasion for any alarm at the effects of Röntgen rays, as exposures of sufficient duration to produce harm are rarely if ever necessary.

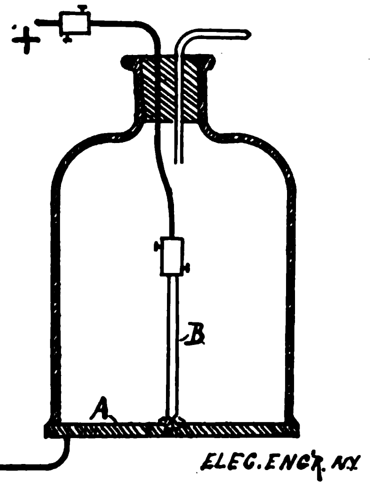
In regard to the claim which has been made that injury only follows exposures made by induction coils, while static machines do not produce the effect, it may be said that in the writer's former experiment, of which the little finger was made the subject, a large capacity static machine was used, and the result was severe enough. The present experiment was made with an induction coil as the source of electric discharges, and as yet there is no difference in the results. The effect is now, of course, limited to two small spots a little distance apart.

MR. TESLA BEFORE THE NEW YORK ACADEMY OF SCIENCES.

ON April 6, Mr. Nikola Tesla delivered before the New York Academy of Sciences an address "On the Streams of Lenard and Röntgen, with Novel Apparatus for Their Production." The lecturer began by stating that in 1894, in experimenting to determine the actinic action of phosphorescent light emanating from vacuum tubes, he had found that the actinic power of Crookes tubes varied greatly, and in the most anomalous manner. Thus some tubes emitting a strong light had very little action on photographic plates, while some showing a feeble light acted very strongly on such plates. A large number of these plates, made by Tonnele for the Century Magazine, were stored in Mr. Tesla's laboratory when it was destroyed by fire, and thus he was unable now to examine them for the Röntgen effects. He believed that he had just missed the discovery which made Röntgen famous and though he was thoroughly familiar with Lenard's work, he did not see far enough.

Mr. Tesla then reviewed his work in the direction of obtaining a reliable apparatus for generating high frequency currents, which he recognized as the keynote to the production of vacuum tube lighting. He told how he had met with difficulties at every point; how a small bubble of air would destroy the value of the coil, or how one-quarter of an inch of wire too much or too little would throw a coil out of balance; how one day a coil would run cold and on another day hot, etc. By finally calling to his aid the condenser, Mr. Tesla stated, he had succeeded in obtaining the desired action and now nothing stood in the way of securing millions of vibrations from ordinary circuits. The lecturer then briefly explained the principle of the condenser discharge as applied to high frequency currents, and pointed to various types of apparatus on the lecture table designed to utilize the principle.

In order to demonstrate the action of the high frequency currents Mr. Tesla attached a circular loop of heavy copper wire to the terminals of a high frequency generator and brought to brilliant incandescence a small lamp connected diametrically across the heavy loop; the illumination of the lamp could be varied by connecting it to various points on the diameter of the loop. Mr. Tesla also lit the lamp by the current induced in a second loop brought in proximity to the first. He explained that the coil accomplishing this work had a resistance of 600 ohms and an inductance of 6 henrys; the coil was connected to the circuit one-half the time and took from the primary circuit only 5 watts.



Tesla's Arc X-Ray Generator.

Mr. Tesla next showed a vacuum tube lit from the terminals of another high frequency machine. He also showed a coil consisting of a single turn of heavy wire which formed the core, as it were, of a small coil of a few turns wound on a paper cylinder surrounding the heavy wire. When connected to a high frequency generator, this apparatus gave a 4-inch spark with an expenditure of energy equal to that taken by one lamp. Mr. Tesla stated that his high frequency generators were so constructed that they could be connected to any existing circuits, direct or alternating.

Returning to the Röntgen rays, the lecturer stated that he had succeeded in discovering a new source of these rays, far more powerful than any heretofore available, though the difficulty of maintaining it was very great. This new source is the electric arc; not the ordinary arc, however. The arc required for the purpose is that maintained between a platinum terminal and an aluminum plate, as illustrated in the accompanying diagram, where A represents the aluminum plate and B the platinum, enclosed in a glass jar.

Mr. Tesla stated that he had also succeeded in deflecting the Röntgen rays by a magnet. He had proved this by deflecting the rays into a condenser placed a long distance from the source of the rays, and which in 5 seconds was charged sufficiently to throw a galvanometer needle off the scale.

ONE of the longest electrical patents ever issued has been granted to Mr. Thaddeus Cahill, of New York. It includes 175 claims for the electrical production and distribution of musical sounds. The apparatus is wholly electrical and bears little if any likeness either in structure on in mode of operation to a piano or organ, though the music produced is said to be similar to that of either. The principle involved is the translation of electrical vibrations into harmonious tones and chords. Mr. Cahill's ability as a maker of claims should render him valuable at election times.

ELECTRIC TRANSPORTATION

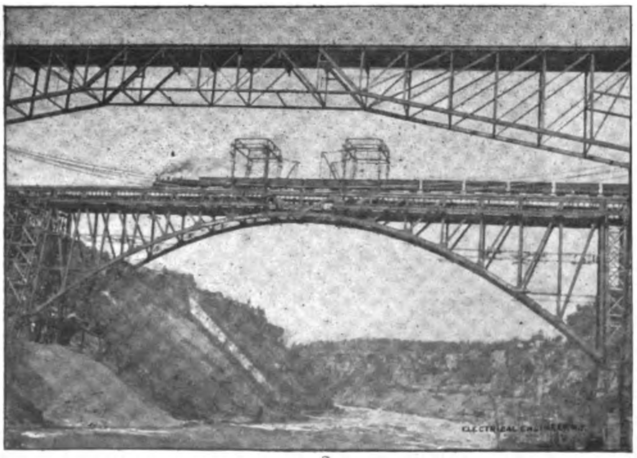
NEW STEEL ARCH TROLLEY BRIDGE AT NIAGARA.

BY ORRIN E. DUNLAP.

IN The Electrical Engineer of Dec. 2, there appeared some account of the new steel arch trolley bridge that is being constructed across the gorge at Niagara Falls. The work on this all-metal structure has progressed rapidly throughout the winter months and it is pleasing to record that, despite the dangerous nature of the work and the dangerous locality, not a single life has been lost, nor has a serious accident happened on the job. The large stone abutments for this bridge are located midway between the water's edge and the top of the high bank on the débris slope. Preparatory to the erection of the steel superstructure, great structures of scaffolding were erected between these abutments and the cliffs, and on these scaffolds the end spans and first panels were built. From this point on, panel after panel, was built in, the work progressing from both sides of the river simultaneously, and gradually the two sections approached one another at a point high over midstream.

It was on Sunday, March 28, that the last panel was placed, and this left the ends of the two great steel sections about two inches apart. To adjust this and allow the end plates of the sections to touch and come together required careful work, and Chief Engineer L. L. Buck was present in person to direct the task. This was commenced on the morning of Monday, March 29, when the men on the work took their stations and the work of adjustment commenced. From the center of the old railway suspension bridge to the great screws at either side of the steel arch at both the Canadian and New York State ends a line was formed, and at a given signal, which was passed along the line, the gangs of men on the screw levers began to turn. This allowed the great steel sections, weighing thousands of tons, to come together. First one corner was lowered and then another, until at last the four screws were operated simultaneously, and the sections met so exactly that the bolt holes in the plates of the two sections matched perfectly, the drift bolts being easily placed. This was indeed the climax of the work, and well displayed the engineering skill that made such an accurate meeting possible. It clearly told what extreme accuracy had been shown in making every member of the arch, and greatly pleased the Pennsylvania Steel Company, makers of the great structure.

It is expected that the arch will be completed in June. It will have a span of 550 feet, which will be connected at the ends to the cliffs by trusses 115 feet long. These dimensions afford excellent opportunity to compare the new arch with other all-metal arches in this country and Europe, the dimensions of which are as shown in the table below.



New Niagara Trolley Bridge.

All who are familiar with the railway suspension bridge, which the new arch will replace, will understand the immensity of the task of constructing this great arch, for it is being built beneath and about the suspension bridge, and this without interrupting the travel of trains or carriages. The illustration presented herewith shows the arch built about the suspension bridge, which it is intended to remove, and which will be a task of no small magnitude.

With the removal of this suspension bridge will disappear one of the most famous structures of its kind in the United States. It was one of the earliest, if not the very first, great suspension bridges ever erected in America. In its original shape the superstructure was of wood, which was renewed in steel in 1880. In 1886 the original stone towers were replaced by towers of steel. It was owing to the construction of the railway suspension bridge that the village of Bellevue changed its name to "Suspension Bridge," a name which is still retained on all railway time tables despite the fact that the village of Suspension Bridge became a part of the city of Niagara Falls in 1892.

EXPLOSION OF RETURN TUBULAR BOILERS AT THE ELMIRA, N. Y. RAILWAY POWER HOUSE.

BY M. C. D.

On March 29, two of the large horizontal boilers in the power house of the West Side Railroad Company, of Elmira, N. Y., exploded, killing the fireman and injuring the engines, besides completely demolishing the power house.

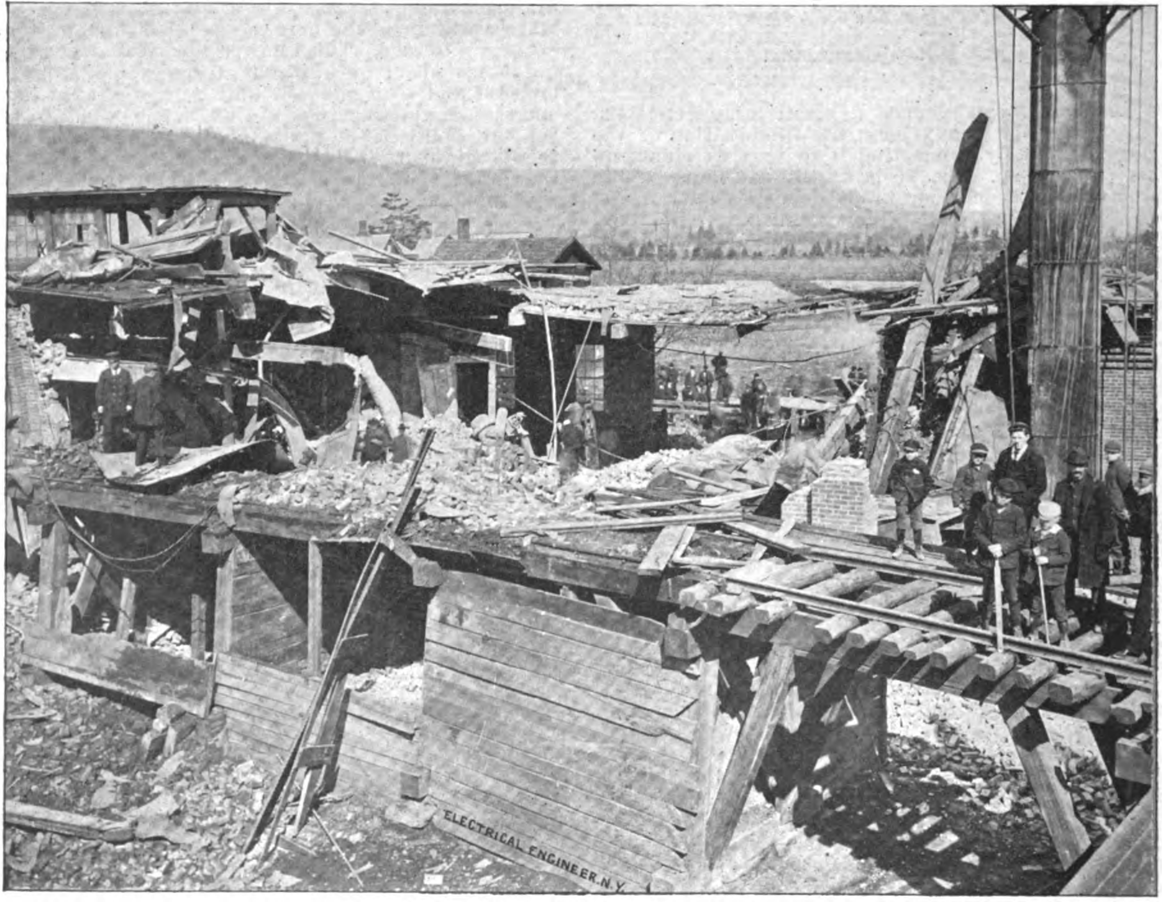
The above is a record that in these modern days of improved steam engineering, is by far too often staring us in the face in large letters in our morning papers. It is read by the public, but soon passes out of mind. While the above item of news applies to Elmira, N. Y., all the difference in preceding items of like news is the name of the town, but the boiler is the same type everywhere. It is persistently used by stubborn, unprogressive engineers or soulless corporations, who want the cheapest they can get.

And a most astonishing thing is that there are insurance companies whose representatives and themselves indorse and recommend such a type of boiler as is here reported. They cannot, no matter how much they try, make a fire tube boiler safe; that is, so that it will not destroy life and property. Then why the modern engineer should stoop to recommend such a magazine of destruction when, if he is up to date, he knows there are safe boilers in the market, with which such accidents cannot possibly happen, is more than the writer can comprehend.

A water tube boiler fills the bill; there is no question about that; the proofs are overwhelming. These Elmira boilers were running at a moderate pressure, being arranged to carry a working pressure of 80 pounds, and all the conditions so far as such a type of boiler was concerned were complete, and the appointments were alike thorough.

The boilers themselves were arranged as is usually done in power houses of this type in batteries of two boilers; the boilers themselves were of the most approved of their type, and according to the modern specification of our steam boiler insurance companies, braced as required by them. The boilers were 16 feet long and 72 inches diameter, with about 70 4-inch tubes arranged tube over tube, not staggered. The boilers were connected to an independent iron stack. The station was in the vicinity of a number of dwelling houses, and it is a miracle that more lives were not lost; but the direction of the explosion may account for that.

As has frequently happened in previous explosions, it was the boiler next the nearest engine that first exploded. The writer's opinion, which is based on many years' close observations, is that this accident, like many others, was caused by the opening of a valve, in a hurry, thus making a sudden draught on the boilers. The nearest boiler, getting the heaviest draught, thus caused the water to suddenly lift up to the steam outlet, uncovering the surface of the shell nearest and over the hot fire in the furnace, causing the surrounding water to immediately flash into steam, at a pressure that no such boiler could withstand; hence the explosion and the devastation and loss of life.



Wreck Caused by Boiler Explosion at Elmira, N. Y., Railway Power House.

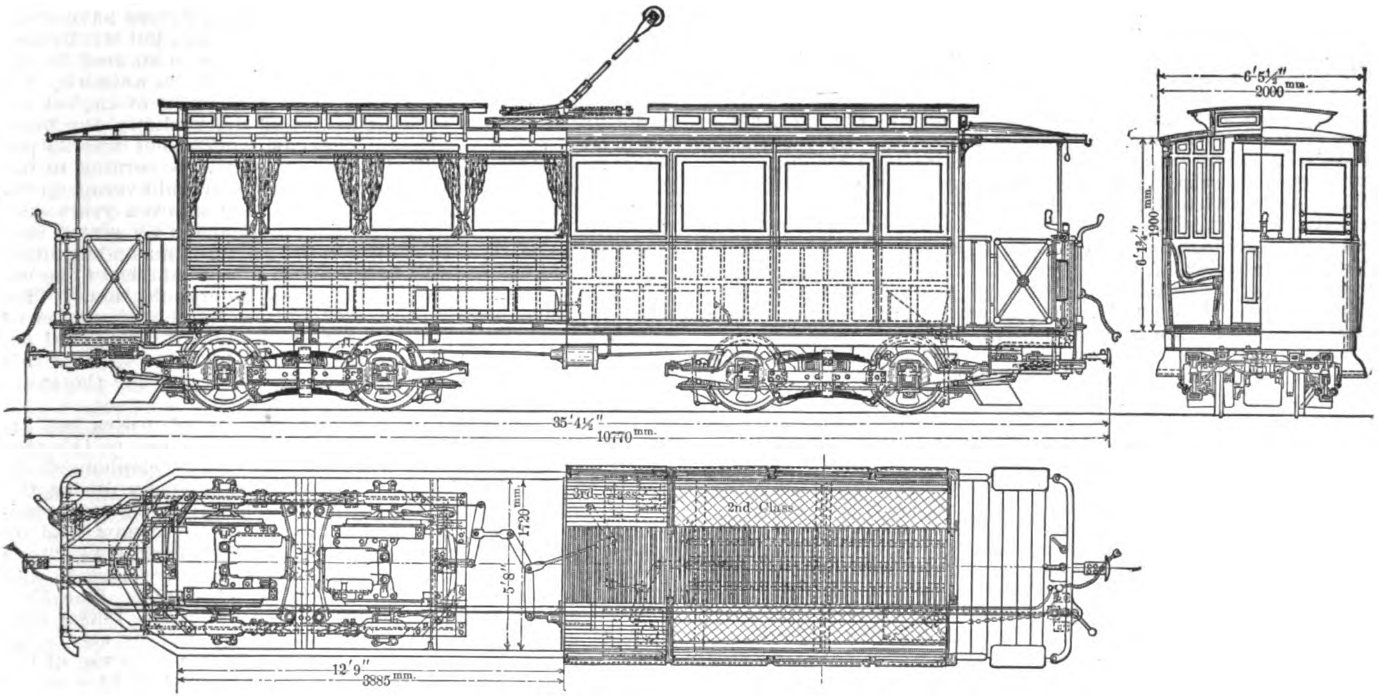
The boiler that exploded first parted on the girth seam, carrying the rivets and part of the outer lap on the rear half of the boiler. The boiler was built in two courses, hence there was only one girth seam riveted. The under side of the shell at the rivet seam in the center of the boiler was split about seven-eighths of the circumference. The top was split central on the rivet centers; one-half of the boiler was driven through the brick wall of the boiler room and for about 1,000 feet into the field, and was driven end on into the earth. At the center line of the rivets on the girth seam the tubes are broken or cracked; all are bent and twisted in every conceivable shape. The braces are broken through the center of the first rivet hole in palm of brace. The tubes in the back head are to some extent driven through. The tubes in this boiler on both ends are all beaded over, an old fashioned practice.

The front half of this boiler shows the force of the explosion. It was driven through cars and landed in a demolished wall a distorted, shapeless mass. In fact, everywhere around this plant the evidences of destruction are seen. I thought while viewing the destruction visible, of how valuable an agent the camera could be made in the hands of an engineer committee, who could have got subject matter of great importance to engineers in general, and proof of the modern needs in the boiler room, and more particularly the ability to convince the doubting that the only safe remedy against such possibilities was to put in a modern improved sectional water tube boiler.

GERMAN INTERURBAN ELECTRIC CAR.

GERMANY is rapidly converting her horse roads into electric, and statistics show it to be far ahead of any other European country in the number of electric roads. The success of the latter has even stimulated the adoption of electricity for interurban traffic, and at the present time a steam road, the Oberschlesische Dampfstrassenbahn, in Prussia, is actually being changed over to electricity.

The accompanying engravings show side and end elevations and a section of one of the cars, of which thirty will be equipped with motors and fifty will be trailers. As will be noticed, there are compartments for both second and third class passengers. The "Standard" air brake, of the Standard Air Brake Company, New York, was specified for the entire installation in view of the satisfactory results which had attended the use of this brake on the Grosse Leipziger Strassenbahn in Leipzig, Germany. On the latter road over 300 Standard brake equipments are in use. Full details of the motor to be used on this car were published in the January issue.



MOTOR CAR WITH AIR BRAKE ON OBERSCHLESISCHE DAMPFSTRASSENBAHN, GERMANY.

The Oberschlesische is a road of extremely narrow gauge, the track having a width of but 30 inches. In order to furnish adequate power, motors will be placed on each axle, that is, four to a car, these motors being of a specially narrow type. There was no room therefore on the axles or the car for the axle type compressor. On this account the gearless motor driven compressor will be used.

The hand brake staff is retained in addition to the air brake, and will operate in conjunction therewith if required. The brake rigging however is arranged to secure uniform pressure alike on all the wheels, and the train when filled will weigh over 50 tons. The steepest grade along the road is 5 per cent. and cars will maintain an average speed of 16 miles per hour. The motor compressor furnished in this installation occupies a space of 16 in. x 24 in. x 18 in.

FINANCIAL PRACTICE AND ENGINEERING METHODS OF AMERICAN STREET RAILWAYS.[1]—I.

BY E. E. HIGGINS.

I THINK it is a good plan in any discussion of this kind to glance at the field of investigation for a moment. There are some things here which have surprised me and possibly may surprise you. Referring to the map, in this very small section of the country covering New England, the Middle States, Ohio, Virginia and West Virginia, there are 64 per cent. of the cities of the United States of over 15,000 inhabitants, there being 215 in all in the Eastern and Central sections of the country, North of Mason & Dixon's line, covering perhaps one-fourth of the area of the United States, there are not less than 83 per cent. of the cities of the United States having over 15,000 inhabitants; south of Mason & Dixon's line, including Texas, there are but 11 per cent., or 24 cities in all; while in the great West, covering an immense area, there are but 6 per cent.

That means that primarily the street railway section of the country is necessarily in the East, because the population is there; and you cannot have street railways without population to support them. That that is true is seen from one or two other statistics. I do not propose to deal very much with statistics to-night, but there are two or three things which may possibly be brought out better in that way than any other.

In the eastern section 44 per cent. of the street railway mileage of the country is concentrated; and in a larger section still, the East and Central East, 76 per cent. is concentrated; while in the South there is but 8 per cent. and in the great West but 16 per cent. The capitalization also is divided in much the same way, 86 per cent. being in the East and Central East, 4 per cent. in the Southern States, and 10 per cent. in the Western States. Now there is another rather interesting feature in connection with this field of street railway operation. It follows from the fact that this immense number of cities is concentrated in this small area, that they must be close together; in other words, we have a network of cities, and the opportunities for suburban and interurban roads are of course very great. In Massachusetts, for example, the whole eastern part of the State is as much of a network in street railroads as in steam railroads, and that is saying a good deal. In New York State it is not quite so much at present, but indications are, if the present rate of growth in mileage is continued, there will be in that State a very large traffic earning power in the fields which have formerly been given over to steam railroads.

---

[1] Delivered before the New York Electrical Society at Columbia University, April 7, 1897.

Now, in the West, it is a matter of fact, and remotely follows from these figures, that the population centers are more or less isolated and the street railways have to rely very largely upon the purely urban traffic. There are of course, in a few of the cities, suburban sections not very far away. Denver, for example, contains numerous health resorts which go far to make up its lack of purely residential suburbs. San Francisco has resorts in much the same general way. But when you consider that there are in the great West but two cities having a population of over 100,000 inhabitants, that there is only one city between 50,000 and 100,000, six between 25,000 and 50,000, and four between 15,000 and 25,000, you can see that the chance for anything more than a merely urban traffic is small.

The same thing in a general way is true of the South. In that section there is only one large city of 100,000 inhabitants, four from 50,000 to 100,000, ten from 25,000 to 50,000, and nine from 15,000 to 25,000. From these figures it follows that we should not expect to find in the West, with one or two conspicuous exceptions, great street railway prosperity, and I shall speak in a moment or two of some of the special reasons why we do not, as a matter of fact, find very large prosperity.

Now just a little bit of history. History is always dry, and I shall not go into it at very great length. I do not know and do not care very much what was the first street railway to be built in the world. It is sufficient to know that between 1850 and 1870, or, limiting it a little more, between 1860 and 1870, was a period of very rapid growth of street railways, all built to be operated by horses.

In 1872 the first cable road was put in operation in San Francisco, and from that time until along in the '80's, cable railroading was a fad with the larger roads. Between 1880 and 1883 there was a great deal of uneasiness among street railway companies. Every one conceded the desirability of doing away with horses and adopting an improved motive power. The question as to what motive power was the real one. The cable was too expensive for most roads. Only a few of the cities of greatest traffic density could think for a moment of putting in a construction costing anywhere from $75,000 to $300,000 a mile. At the same time the municipalities were urging the improvement; the newspapers were calling upon the street railway companies to give better service into the suburbs; real estate syndicates which had property to sell were bringing the question up in every way possible, and the difficulties of the street railway manager could hardly be exaggerated. Compressed air motors, gas motors, ammonia motors, and perhaps more than all, the storage battery system were considered among the most hoped for possibilities.

At that time no one believed it possible that the roads could put in the overhead electric system, even if the overhead system could be proven to be successful, on account of the opposition to it on the part of municipalities. In 1888, the Richmond Road was first operated. The history of that road in its early fight of electric traction versus horse traction is interesting. I suppose that Mr. Sprague spent the greater part of six months on his back under the cars at Richmond trying to get his motors to work, and the fact that he succeeded was the result of one of the most indomitable and plucky fights that has ever been made in any department of industrial development. The original Sprague motors were single reduction, very light indeed, poorly constructed, easy to burn out, over-loaded under the usual conditions of traffic, particularly at Richmond. Later motors brought about a double reduction through the use of internal gearing.

The Thomson-Houston Company entered into the fight with its accustomed energy and during the next three or four years, there was one of the most remarkable "booms"—it is hard to find a word which expresses so much as this word—in electric railroading that could possibly be imagined. It would not have been believed possible in 1888 that so much mileage of the overhead system could be put in in three or four years.

In 1892 electric traction was practically determined upon by all street railroad managers. The cable system was no longer considered, and from 1892 until the present time, cable mileage has actually been cut down, not because cars cannot be operated more cheaply than by electricity, for as a matter of fact, in many cases where the traffic is very dense, the cable system is still more economical per car mile, but because the electric cars were more popular, insured smoother riding, better lighting, and, as a rule, between the two motive powers, electricity had so many points of advantage, so far as the public were concerned—the poles and wires being in—that the cable companies in some cases were forced to adopt electricity or go to the wall.

The result is that to-day out of 15,000 miles of street railroads in the United States, 85 per cent. are in operation by electricity as against 8 per cent. by horses (only 1,200 miles), 4 per cent. by the cable system, and 4 per cent. by miscellaneous motive power, chiefly steam dummy lines. So much for the history of electricity as a motive power for street railways.

TELEPHONY AND TELEGRAPHY

DISCUSSION AT ALBANY OF THE NEW YORK TELEPHONE RATES.—MR U. N. BETHELL'S ARGUMENT.

At the hearing, at Albany, on Thursday last, April 8, on the Brush bill to regulate telephone charges, the telephone side of the case was presented by Mr. U. N. Bethell, the general manager of the New York Telephone Company. In answering the arguments of the supporters of the bill he took up the statement made at a recent hearing that the Ainsworth committee report showed that in 1885 the Metropolitan Telephone Company made a profit of 116 per cent., in 1886 of 147 per cent., and in 1887 of 145 per cent. Such figures have often been quoted before in support of telephone bills, but Mr. Bethell showed by a full citation of the statistics contained in the Ainsworth report that there was absolutely no authority for them. By disregarding various important items of capital expenditure necessary to the conduct of the business, the highest percentage of profit that could be worked out was 33 per cent., and even this was a fictitious figure. According to the figures given in the Ainsworth report, the actual average profit of the Metropolitan (N. Y.) Company for the seven years ending with 1887 was 9.66 per cent. The report itself stated that "The evidence shows that the substitution of an underground for an aerial system will entail a loss of three-fifths of the entire net earnings of the company since its organization." This statement had always been disregarded by the advocates of telephone rate bills, and they had manipulated the capital account of the company to suit themselves; but even with all this there was absolutely no authority in the report for the exaggerated profits cited before the committee.

The present bill had been drawn, and its advocates had argued for it, said Mr. Bethell, with sole reference to the rate of $240 a year, as if that were the New York Telephone Company's only rate. The work done by the company during the past three years in modifying and reducing its rates was wholly ignored. As a matter of fact the $240 rate is now paid by a comparatively small proportion of New York subscribers and is paid by them because they use the telephone largely, and it is to their advantage to have unlimited service. The New York Telephone Company has at present some 18,000 subscribers, of whom about 4,300, or less than 25 per cent., pay the $240 rate. Of these 4,300, there are 2,500 whose use of the service is such that they can get all they require at a lower rate by contracting on the message rate plan at the schedule now in force. This leaves only 1,800 subscribers, or just 10 per cent. of the total number in the system, whose demand on the service is such that it is an advantage to them to take the unlimited service and to pay the $240 a year, which is the present price of it.

Consequently the proposed bill is aimed to relieve a class of large users of the telephone service, large firms and corporations doing an extensive business, at the expense of the large majority of the subscribers whose use of the service is limited, but necessary to their affairs or their comfort. This larger proportion of the subscribers contract on the message rate basis, and their actual average rate is considerably less than the uniform flat rate laid down by the bill.

The flat rate system of charging for telephone service was the plan naturally adopted in the early days of the telephone exchange, when the exchanges were small the service restrictd and the call on the service and on the plant about the same in the case of every subscriber to the exchanges. As the exchanges grew in size and spread out over large cities increasing the cost and complication of the plant, and as the demands of the subscribers on the service began to vary in natural proportion to the wide variance in their business activity and importance, the disadvantage of the flat rate began to be apparent. The steadily increasing cost of the plant and growth in the general use of the service could only be met by a corresponding increase in the general rate, an increase easily met by large concerns to whom almost any price for telephone service would be an insignificant item of their general expenses, but which bore heavily on the moderate customer who is the mainstay of every business. The cure for this situation was found by striking at the heart of the problem. Instead of taking the subscriber's line and station as the unit of value in the supply of telephone service, which has been generally done since the beginning of exchange telephony, the telephone message or connection was taken as the unit and a new system of rates for New York City was studied out on this basis.

A very short consideration of the subject would convince any investigator that the message rate system is the proper solution of the telephone rate problem in a large city like New York, even were there not the remarkable success of the system during the three years it has been in existence to point to as proof of its correctness.

In the early days of the telephone exchange a single exchange served each system and the amount of plant used for each subscriber and operating labor required for each subscriber was approximately the same. A uniform rate was naturally found satisfactory by all concerned and as time went on this rate was naturally considered to be for the hire of a telephone instrument and line, and the actual service performed was lost sight of. But as the telephone systems grew in number of subscribers and extent of area covered, it began to be apparent that the service and not the line and instrument was the main point. With larger areas to serve, numerous exchanges had to be established, and these exchanges had all to be interconnected by trunk lines to carry calls from one district to another. Hence in New York, although a subscriber's line to the exchange may be only half a mile or even a few hundred feet long, he often uses trunk lines five, ten or even fifteen miles long to reach his correspondent in another part of the city. This transfer of calls from one district to another, and in New York the great majority of calls are so transferred, greatly increases the cost and complication of the operating as compared with that of a self-contained single exchange system. The subscriber, however, never appreciated how it made any difference to the company whether he sent few or many messages. He was accustomed to think that he paid for the hire of a telephone—the telephone was there and might as well be used. The messages, however, were what really counted and a subscriber's line was profitable or the reverse to operate according as it gave origin to few or many messages—as it made a light or heavy demand on the operating labor and on the trunk line system joining the various central offices.

Working on this principle the Metropolitan Telephone Company evolved a schedule of rates based on the amount of service supplied. The message rate principle had been adopted years previously in Buffalo and had been heartily indorsed by the Ainsworth committee in its report. In dealing with this subject the report said: "With a fair minimum rate as an equivalent for the possession and right to use the telephone, and a reasonable scale of prices for connections, if used, the toll system seems to have for both customer and company marked advantage over the flat rate."

In adopting the message system the company was conservative and proceeded cautiously, after an extended study of the subject and a careful examination of the working of the system in Buffalo. The plan was offered to customers as an alternative to the flat rate and was in no way obligatory on old or new customers. The first schedule was adopted in June, 1894, with a minimum rate of $150, the style of equipment and grade of service being exactly the same as those supplied at the flat rate of $240. After a little experience in the working of the system a reduction of the minimum rate to $120 was made in November, 1894. In the light of still further experience with the new scheme of rates, which found immediate favor among both old and new subscribers, a revised schedule was put in force in May 1895, under which the minimum annual rate was $75 for a line shared with another subscriber and $90 for a direct and exclusive line. These rates include the right to send 600 outward local messages and to publication of the subscriber's name, telephone number and address in the company's quarterly directory. The charge for additional messages decreases as the number contracted for increases, ranging from 10 cents down to 5 cents per message. If the subscriber to secure the lowest price for messages contracts and pays in advance for more messages than he subsequently used, the unearneu portion of the advance payment is refunded. An adjustment is made at the end of each contract year so that the subscriber pays in exact accordance with his use of the service. When the subscriber guarantees to use a fixed number above 1,500 messages, liberal discounts are made. For payment of the yearly rate in advance, the number of messages covered by a given rate is increased by 10 per cent.

It should be borne clearly in mind that at these rates with their various attractive features to businesslike customers the highest grade of telephone service known to the world is supplied; and the $75 or $90 customer gets exactly the same style of line and instrument, switchboard facilities and the same command over the vast trunking system as his $240 neighbor. The only difference is that he doesn't use them so much. He also gets the same advantage from the technical improvements constantly introduced into the system and from the increase in the area and scope of the system. The only difference between one customer and another is in their respective use of the service.

Another feature of the liberal policy of the company in adopting this method of charging for telephone service—the practical result of which has been a large reduction of rates—is that the method was not aimed solely at acquiring new business, but the new rates were at once made available to all old subscribers paying the flat rate and new contracts were made with all those who found that they could make a reduction in their telephone expenses by coming under the message rate schedule and chose to adopt that schedule.

The message rates had been persistently advertised for the past three years in the daily and weekly press, in street cars and other public places and by means of numerous special circulars sent broadcast over New York. The message rates have been adopted by or are available to, at an economy, all but about 10 per cent. of the company's subscribers and under the message rates a majority of the company's subscribers pay an average rate considerably less than the rate named in the Brush bill.' Yet the advocates of the bill ignore all this, have heard nothing of any reduction in rates and persistently speak of the $240 rate as if that were the only price at which telephone service could be had in the city of New York.

The introduction of the message rates and the hearty support given them, as evidenced by an increase of 6,165 subscribers in the two years ending Dec. 31, 1896, brought the advantages of telephone service home to many who had been unable to consider its use when the flat rate was the only rate available. At the same time the company was enabled to accelerate the transformation of its system to complete metallic circuit working, for whereas in May, 1893, there were more than 5,000 subscribers or nearly half the system still using single wire grounded circuits with old style instruments, at the close of 1896 all this old-fashioned material had disappeared and all subscribers experienced the benefit of complete metallic circuit working. This extensive reconstruction of the plant has been accompanied by a marked improvement in the organization and discipline of the staff, the general result being a grade of service that is unapproached anywhere. Even the supporters of the bill testify to this and say they have no complaint to make of the service.

To put what has been explained above into figures, the following statement was offered. The New York Company operates about 1,500 public stations for the convenience of the non-subscriber and occasional user. At these stations charges are made by the message, but they are not included under the regular message rate subscriber stations. There are also about 1,500 stations at low flat rates averaging less than the rate fixed in the bill. This leaves in round numbers 10,700 stations receiving service at message rates. The average rate paid for service at these stations is less than $109 a year. This sum, the average rate of over 10,000 subscribers, is considerably less than the uniform rate named in the bill—$125—and this fact alone should be enough to show conclusively that it would be ill-advised and improper. If the bill were made a law it would benefit some 1,800 subscribers who already get more than they really pay for, while it would raise the average rate of 10,700 others by at least $16 a year.

The class of large users who hold to the $240 flat rate is not an increasing class. On the contrary, it is constantly diminishing. And those who are deserting it, strange to say, are the largest users who are taking up the message rate system in order to get improved facilities and a more elastic arrangement of their telephone facilities. A line that is used very largely is frequently reported "busy" to important incoming calls. Many lines in New York City are reported "busy" fifty times a day and some as often as 250 times. The only cure for this evil is additional lines, as its existence shows that the telephone facilities to a given point are insufficient for the traffic. Under the message rate plan extra lines may be had at the most economical rate and large users are adopting the plan and fitting up their premises with veritable miniature telephone exchanges on the message rate plan in place of the one or two flat rate lines they formerly had. A switchboard is placed in the subscriber's place of business and from this radiate lines connected to telephones placed at the different desks or in the different departments of the establishment. The switchboard is connected to the nearest central office by means of several, sometimes ten or a dozen, trunk lines. This makes a most flexible system for handling a large amount of telephone traffic and the charges are based on wholesale principles. The facility of using the service is much improved. There is no running to the telephone, no "holding the line" for each user has a telephone at his right hand. No waiting in turn, for there are enough trunk lines to the main system to avoid crowding. And above all, there are no "busy" reports to those calling for connection from without. These telephones—all long-distance instruments of the most improved type—are charged for at $24 a year each; the lines to the central office at $36 a year, the switchboard and 4,000 local messages at $160 a year, and additional messages at 3 cents each—cheaper than postage. Large concerns of all sorts are now taking advantage of this plan to provide themselves with adequate telephone facilities at a fair price. Under the same plan tenants in large apartment houses secure telephone service at a rate of $2 a month and a small toll on each message. All this, Mr. Bethell pointed out, had become possible under the message rate plan, which the Brush bill seeks to set aside.

A NEW AUTOMATIC ELECTRIC BURGLAR ALARM SYSTEM.

MUCH ingenuity has been displayed in contriving means for frustrating the efforts of burglars, and these efforts have yielded a variety of devices in which electricity plays a prominent part. The most recent work in this field is that now being brought out by the Bankers' Electric Protective Company, of Chicago. The system is entirely "local," and dependence is placed upon the integrity of circuits within the building containing the property to be safeguarded.

The engraving, Fig. 1, shows the cabinet which is used to surround the safe or other object to be protected. Where the safe is kept in a vault the vault serves the purposes of a cabinet. In either case an electric lining is used, consisting of strips of metal mounted in connection with thin metal sheets, so arranged that even a pin thrust through the cabinet and penetrating the lining will sound the alarm. The door cannot be opened, or curtain raised, until the time-lock has disconnected it from the alarm system.

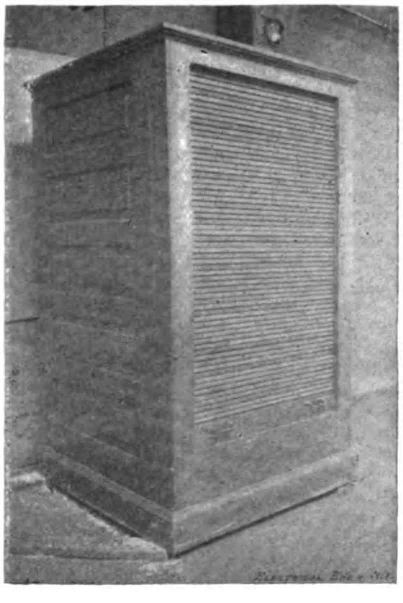


FIG. 1.—CABINET SURROUNDING SAFE.

Fig. 2 shows the current indicator which is used to guide in the opening and closing of the system and also to show the condition of the current during the day, at which time the needle should normally stand at number 5, and for the purpose of keeping a record of the system customers are furnished with addressed postals, one of which must be regularly mailed at stated intervals. After closing the curtain, the needle stands at the red mark or middle position. After pushing the button located on the outside of the cabinet, it will go to the "Shut" position, showing that the alarm has been switched onto the curtain, at which position it will remain until the chronometric switch throws the current off of the curtain, when it will again stand at red mark, showing that the curtain is in a condition to be opened without causing an alarm, and will again come to the open side after the curtain is raised.

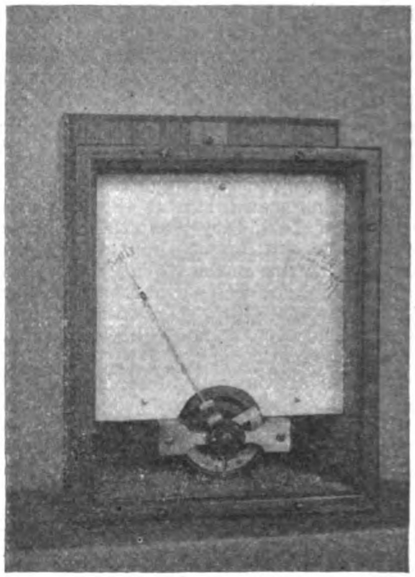

FIG. 2.—CURRENT INDICATOR.

The timer and controlling instrument, Fig. 3, of steel, is located inside of the vault or cabinet in a convenient and accessible place and contains chronometric switch, push buttons, galvanometer, resistance coils and terminal board. In the closing of the system, the chronometric switch is first wound for the number of hours the alarm is desired to be on, then the push marked "On" is operated, when the galvanometer needle will be deflected and prove that all switch instruments in the alarm box are on, then after closing the curtain the indicator on the outside of the cabinet shows that the proper contact is established on contacts and also that the alarm is on after pushing the button under it.

Fig. 5 shows the alarm box as it appears from the outside, provided with storm hood. It is made of steel; the front and back are constructed of heavy double angle gratings to provide for acoustic qualities for an 18-inch gong. The whole is lined in a similar manner to that of a cabinet, so that any attempt at tampering will cause an alarm to be sounded the same as would be the case if the cabinet were molested. The door is held closed by numerous heavy lag bolts, the partial removal of any one of which will cause an alarm, and in order for the door to be opened it necessitates the removal of all of them, which requires a considerable length of time.

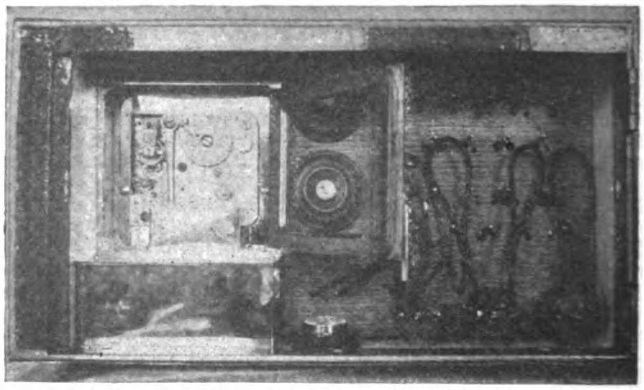

FIG. 3.—TIMER AND CONTROLLING INSTRUMENT.

The relay instrument, Fig. 4, is located in the alarm box, the batteries for operating and controlling it being inside of the cabinet or vault, and is so made and adjusted, combined with the strength of batteries and proportions of resistance coil, that just sufficient current flows through it to maintain its pointer or contact arm balanced between two local contact points, so that any disturbance in the way of an increase or decrease of this normal amount of current will cause the pointer to contact with one of the screws on either side of it and so close the local circuit and cause an alarm.

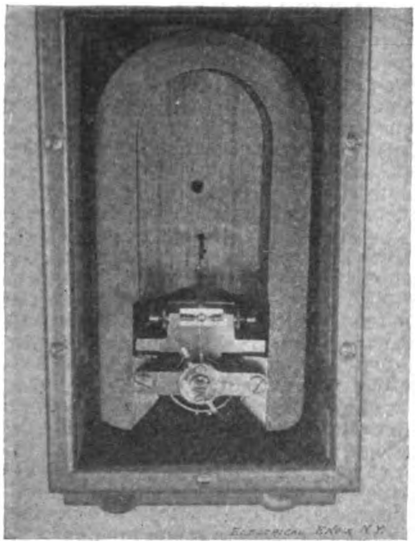

FIG. 4.—THE RELAY INSTRUMENT.

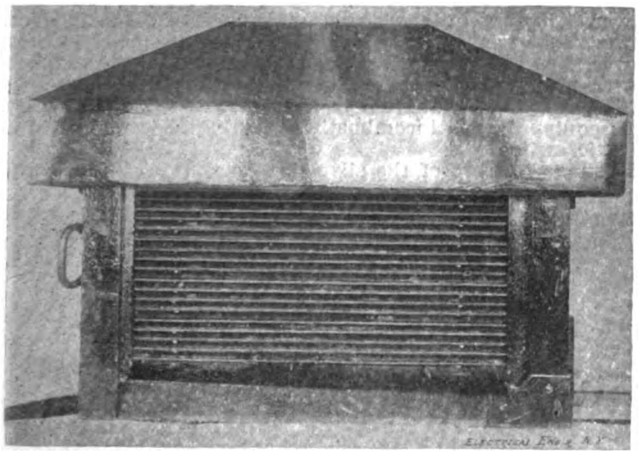

FIG. 5.—THE ALARM BOX.

OBITUARY

DR. HEINRICH VON STEPHAN.

Dr. Heinrich von Stephan, who died in Berlin on April 7, was for more than a quarter of a century the German Imperial Postmaster-General. He was born in 1830. Beginning in 1849, he devoted himself to the postal service, and his promotion from grade to grade, after entering in 1856 the general office in Berlin, was steady and rapid. He was identified with the establishment of the Universal Postal Union, which now includes in its benefits almost every nation. He introduced the telephone system into the German postal service and established the pneumatic system of postal transmission wherever possible. He was honored repeatedly by decorations and otherwise, as a result of his administration of his department.

MR. E. T. COGHILL.

Mr. E. T. Coghill, a former resident of Richmond and manager of the Southern Bell Telephone Exchange at Wilmington, N. C., died in that city on March 29, of a congestive chill very suddenly. Mr. Coghill was a son of the late William T. and Mrs. Hardinia Coghill. His age was about thirty-five years. He resided in Norfolk, Va., up to about eight years ago, when he went to Wilmington for the telephone company. He was a man faithful to every trust and held in the highest esteem by his many friends.

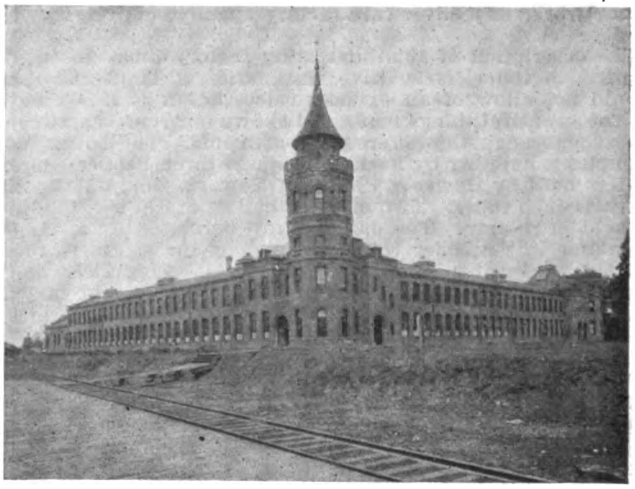
MR. G. LA F. MORRIS, president of the Birmingham (Ala.) Consolidated Electric Light Company, and a large shareholder in the Birmingham Railway and Electric Company has died, aged 48. He arrived in the city a poor man, but amassed a handsome fortune.

MR. H. E. JENNISON, superintendent of construction for Western Union Telegraph Company, was asphyxiated by coal gas on March 26 in the Burk railroad tunnel at Leadville, Colo., while directing some repairs to a cable. He was 60 years of age and a resident of Omaha.

POWER TRANSMISSION

MAKING TIFFANY SILVERWARE BY ELECTRIC POWER.

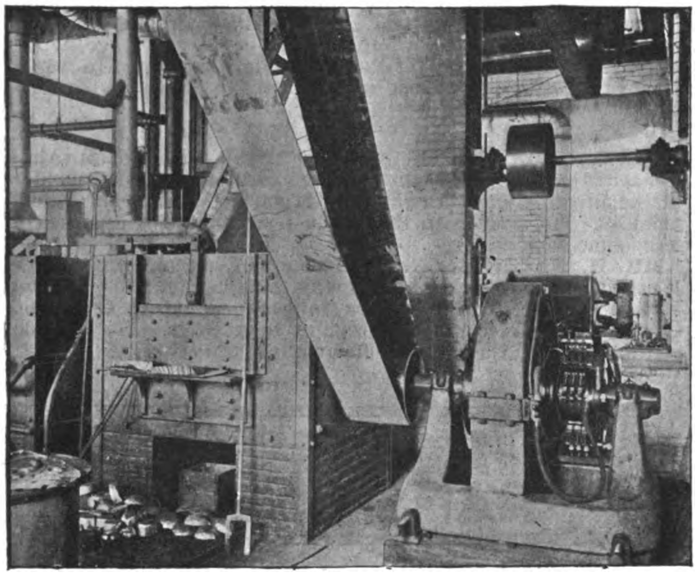
THE famous silverware factory of Tiffany & Co., so long located in the heart of New York, has been removed to Forest Hill, near Newark, N. J., where a new and spacious modern building has been prepared to receive this department of that great business, from which has come metal work of such a highly artistic character as to recall the glorious days of Benvenuto Cellini and the great artisans of the Cinque Cento. Here deft workers will handle the pale metal under better physical conditions, until it assumes manifold forms of ornamentation from the simple impression of the decorative silver spoon to the intricate colored silver and enameled work which vies with and rises superior to the creations of the best English and French silversmiths. This striking supremacy was acknowledged by the industrial and art papers of England and France during the last two great French exhibitions, when Tiffany & Co. secured the medal of honor—the highest award. Tiffany & Co. is an American institution and in no way is this more forcibly demonstrated than in the practice adopted in that part of it now located at Forest Hill.



TIFFANY & CO'S FACTORY AT FOREST HILL, N. J.

In this factory, everything with but few exceptions is modern—the building, the machinery, and, last, and most up to date, the method of driving it. The entire steam engine plant is confined to one room, the power is distributed by electricity over a two-wire 250-volt direct current system carefully laid out and as carefully executed. The entire electrical apparatus is of General Electric Company make, installed by the New York office, and is of the most recent manufacture.

The factory consists of a main front looking southeast and three wings extending northwest, built of brick and stone, two stories high with a spired tower on the south corner. It is 350 feet long by 300 feet wide and is divided into fifteen fireproof compartments. The first wing running along the side of the Erie Railroad, and part of the front was constructed some two years ago. To this building was removed the plated ware department, the motive power for which was furnished by a 50-horse-power engine. On the adoption of electric drive this was superseded by a 4-pole 50-horse-power 850-revolution motor.



50 H. P. Motor in Plated Ware Department.

The other two wings of the factory have been built during the past year and run parallel with the first, but are closed at the northwest end by the engine room, forming a large two-story building around a spacious central court yard. In this building the entire silverware manufacture of Tiffany & Co. is now carried on, under the superintendency of Mr. Parsell, to whose kindly courtesy we are indebted for data and facilities. This factory is the first instance, so far as we are aware, in the world of a silverware factory operated entirely by electricity.

The description of this interesting factory must, for us, be limited to the electric drive installation. Time and space would not allow of an extensive description at this time of all the beautiful things made and shown our representative on his trip through the different departments. The boiler room occupies a building by itself. It houses three 100-horse-power boilers built by Hewes & Philips of Newark, 66in. x 16ft., with 96 three-inch tubes. Two of these boilers are in use, the third is held in reserve. The dampers are regulated by a damper regulator in the boiler room operated by the steam pressure. All the feed water is filtered through a Blessing filter, and a special meter is provided for any boiler trials that may be necessary. The boiler room also contains a Worthington fire pump of 1,000 gallons capacity, connected to fifteen fire stations, one to each of the fireproof compartments. The steam piping is in duplicate, and is covered with Johns asbestos packing.

A covered passage leads from the boiler room to a handsome engine room which is a model of its kind. The main engine is a 250-horse-power 490-revolution Corliss, also built by Hewes & Philips of Newark. It is belted by a 28-inch belt to a countershaft running the entire width of the room, to which is also belted as an auxiliary the horizontal Ball & Wood engine of 50 horse power. This engine formerly drove the machinery in the plating department, but since this department was included in the electric drive scheme, the engine has been removed to the engine room proper. It will be used as an auxiliary in cases of light load when the factory is running overtime.

All the bearings are of the Hyatt roller type. Standing beside the main engine is a Phole air lift drawing the water from the artesian well, and a steam pump forcing it up into the tank on the corner tower.

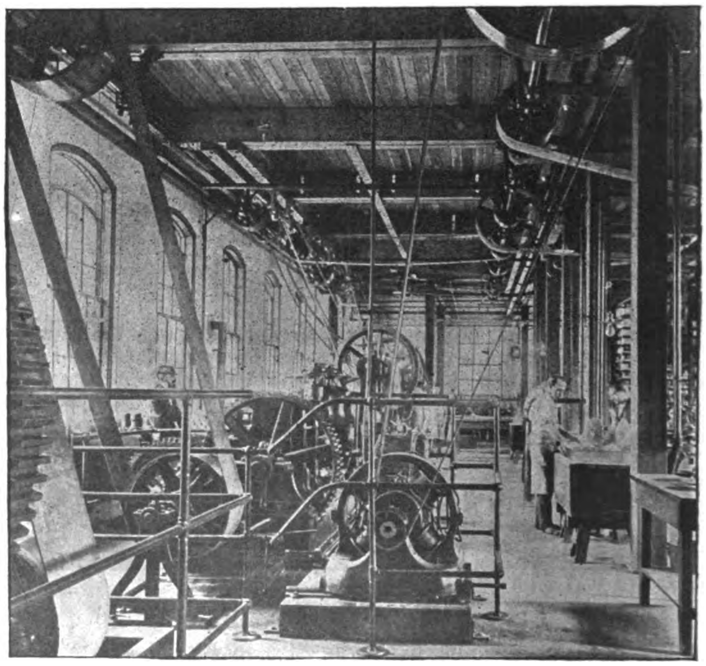
The countershaft is equipped with Worrall cut-off couplings by means of which either or both of the generators may be driven. To it are belted two General Electric moderate speed multipolar generators, each four pole, 100-kilowatt 750-revolution machines, delivering current at 250 volts. These generators are of a type which has recently come into extended use. The frames and pole pieces are of special soft steel. The armatures provided with air ducts are thoroughly ventilated, and the coils of copper wire made on forms before being placed on the core are bound down solidly at both ends on cylindrical flange extensions of the spider. The bending of the armature coils is thus avoided and they can be removed and replaced easily and speedily. The insulation used is similar to that employed in the G. E. railway motors, and is both tough and impervious to moisture. The brushes are of carbon set in specially constructed holders to give proper contact on the commutator.

The blue Vermont marble switchboard is composed of five panels. The center panel carries a voltmeter and voltmeter switch, and twelve knife switches, six for the lighting feeders and six for the power feeders. The two panels on each side are generator panels and each is equipped with ammeter, main switch, field switch, rheostat, pilot lamp and a G. E. automatic magnetic blow-out circuit breaker. The two outside panels carry four switches; on the right panel two for lighting and two for power in the case factory; on the left panel two for lighting and two for power in the plating department. All the switches are of the G. E. quick break single pole pattern.

The leads from the generators are carried to the switchboard beneath the floor. From the switchboard the feeder circuits rise to the ceiling of the engine room, and, carried on porcelain insulators, in lines as straight as possible, pass to the various points of utilization in this interesting factory. In all passage ways on the floor of the engine room corrugated rubber is laid down, and all the machinery, both steam and electrical, is surrounded by polished brass railings.

The motor equipment consists of three I. B. motors, 2-pole, 3 horse power, 1,800 revolutions; two I. B. motors, 2-pole, 5 horse power, 1,700 revolutions; one M. P. motor, 4-pole, 8 horse power, 1,600 revolutions: four M. P. motors, 4-pole, 10 horse power, 1,350 revolutions; three M. P. motors, 4-pole, 15 horse power, 1,200 revolutions; one M. P. motor, 4-pole, 20 horse power, 1,050 revolutions; two M. P. motors, 4-pole, 30 horse power, 975 revolutions; one M. P. motor, 4-pole, 50 horse power, 850 revolutions, allotted to the different departments, and each equipped with incombustible starting rheostats with automatic switch.

The manufacture of the silverware may be said to start in a room on the first floor of the central wing, separated from the engine room by a driveway, and known as the smelting and refining room. This contains a cupola and cupel in which the refuse of the factory is treated. All the dust and refuse from the benches, floors and polishing tables is collected either by a powerful exhaust fan in a huge receiver or is carefully swept up, and moulded into cakes, is introduced into the



20 H. P. Motor in Spoon Making Room.

cupola and melted down. The hand washings are all collected into huge tanks and filtered to collect the metal dust. Nothing is wasted. Every scrap of the precious metal is recovered and turned back into the factory.

Next to this room is the moulding room, containing melting furnaces, casting machines, sand mills and boxes, etc. Here the casting is effected. This room contains a 4-pole 15-horse-power 1,200-revolution motor, belted to overhead shafting operating blast blower, moulding machinery, etc. In the next room, known as the stamping and rolling room, it drives a series of drop presses under which the silverware is stamped into the beautiful designs, which are associated with the mere mention of the name of Tiffany. This room also contains a large rolling mill, where sheets of silver one yard long and more, by two feet wide are rolled down to required thickness, toggle press and a hydraulic press of 1,000 tons capacity with its pump, all driven by a 4-pole 30-horse-power 975-revolution motor, also belted to ceiling countershafting.

The next room occupies the remainder of the length of the wing and is known as the spoon-making room. Here the plain sheets of silver pass through the various processes to emerge in the shape of spoons of all patterns ready for the polisher's table. The heavy machinery in this room consists of two large rolling mills; the light, of five presses, four spoon mills, four filing lathes, four drop presses, one shears, one saw lathe, one reversible mill and one burr lathe. All this is driven by a 4-pole 20-horse-power 1,050-revolution motor also set upon the floor and surrounded by a brass railing. The only device not driven by electricity in this room is the steam hammer.

Mounting a spiral staircase in the corner of this room we emerge upon the second floor, and find ourselves in a large L-shaped room occupying almost the entire front and the southeast corner of the new building. This is devoted to the silversmith's small work, mounting, etc., and is driven by two motors both mounted on small platforms. That in the long leg of the L is a 2-pole 3-horse-power 1,800 revolution motor; that in the short L is a 2-pole 5-horse-power 1,700-revolution machine. As its name indicates, the work done here is of a small character, and from this room come the delicately worked articles such as boxes, buckles, brushes, mirrors and other articles for the boudoir, writing desk, etc. The greater part of the work in this room is bench work. The machinery driven by the smaller motor consists of emery wheels, burr lathes, drills, etc. That driven by the larger motor comprises one circular saw, one jig saw, one burr lathe and one turning lathe, one shears, one rolling mill and a grindstone.

The next room is the stock room, in which blanks are cut and wire drawn. This is equipped with a 2-pole 5-horse-power 1,700-revolution motor mounted upon a stand, driving a wire draw bench and five mills in which silver borders for teapots, coffee pots, cups, etc., etc., are rolled.

Adjoining this is the spinning room, in which are eleven spinning lathes, three turning lathes, a large and a small circular saw, an emery wheel and a grindstone. All this is driven by a 4-pole 8-horse-power 1,600-revolution motor, set upon a low table and belted to ceiling shafting. The remaining length of the second floor on this wing is devoted to silversmith's work. In this room, as in that given up to the silversmith's smaller work, a great part of the work is done at benches. The machinery is small and consists of two swedges, one saw and drill and one burr lathe. The motive power is a 2-pole 3-horse-power 1,800-revolution motor, mounted upon a raised platform.

Following this room is the gilding room, in which the machinery consisting of the three plating dynamos and two scratch brushes is driven by a 4-pole 10-horse-power 1,350-revolution motor. One of the plating dynamos is a Wilde machine imported many years ago, but still active. From this room entrance is gained to the etching, enamelling and fancy finish room. This room contains a series of polishing wheels, scratch brushes and drills all driven by a 4-pole 10-horse-power 1,350-revolution motor. Here the exquisite enamelling and niello work is done.

The next room is the chasing department in which as the work is done by hand no motor is required, and adjoining this is the engraving and die sinking department, in which light machinery is driven by a 2-pole 3-horse-power 1,800-revolution motor. The remainder of the second floor in that wing is the designing room.

Descending to the first floor, and passing through a door behind the engine room countershafting brings us to the machine shop, in which all machinery repairs are made. The machinery in this room consists of lathes, planers, shears, shapers, milling machines, cutters, etc., all driven by a 4-pole 10-horse-power 1,350-revolution motor, mounted on a stand and belted to ceiling countershafting. A second motor set on the floor is a 4-pole 15-horse-power 1,200-revolution machine belted to a shaft running through the wall into the brushing and bobbing room. This room contains another 4-pole 15-horse-power 1,200-revolution motor, also belted to ceiling countershafting. From the ceiling countershafting two belts are brought down to shafting running beneath the brushing and bobbing benches. To the uninitiated "bobbing" is smoothing off irregularities on the silverware by means of a walrus hide disc; "brushing" is the polishing operation, after the silverware has been "bobbed."

At the side of the brushing and bobbing rom is a small room containing a Sturtevant exhaust fan and an exhaust tank, a McKenzie blower and a large Root blower driven by a 4-pole 30-horse-power 975-revolution motor. The exhaust fan draws all the dust from the brushing and bobbing tables into the tank, where it is collected for reduction in the smelting and refining room.

The polishing in the brushing room is the preliminary polishing of the silverware. From this room it passes to the finishing and polishing room, when the final polish is given to it. The rouge lathes are enclosed in a glass chamber and an exhaust opening faces each wheel. This department has a 4-pole 10-horse-power 1,350-revolution motor for its machinery, which in addition to the rouge lathes consists of a burnishing lathe, a grindstone and a scratch brush.

The last work room of the factory is the repairing department, where all repairs to costly silverware, in many instances impossible to duplicate, are made. This is equipped with a 2-pole 5-horse-power 1,700-revolution motor driving monitor and turning lathes, drills, saws, and presses, emery wheels, etc. Through a window in the side of this room all the finished work is passed into the office whence it is shipped to the store in New York.

The new building is lighted by 1,190 250-volt 16-candle-power lamps, the old building or plating department by 199 250-volt 16-candle-power lamps, all furnished from the generators which supply the current for the motors.

SOCIETY & CLUB NOTES

CINCINNATI ELECTRICAL CLUB DINNER.

The Cincinnati Electrical Club spent Friday evening, April 2, at dinner and a social meeting at the Gibson House. The addresses of the evening were delivered by Mr. T. J. Creaghead, Mr. Bert Baldwin, Mr. C. E. Jones and Prof. Thos. French, Jr. Mr. Jones' history of the beginnings of electricity in Cincinnati, and Mr. Baldwin's recountal of the developments of electricity in street railway work were full of value to men of the electrical fraternity and elicited an animated discussion.

Among the gentlemen present were: Messrs. Wm. M. Venable, Hugo Diemer, G. J. Smith, Alfred Knight, David Hall, L. E. Bogen, Wm. B. Hubbell, E. M. Lawton, P. H. Trout, Geo. Hafer, Jr., E. A. Sarran, W. G. Reuter.

ELECTRICITY AT THE NEW YORK ACADEMY OF SCIENCES.

THE fourth annual exhibition of the New York Academy of Sciences was held on April 5 and 6 at the American Museum of Natural History. The Department of Electricity, in charge of Mr. G. F. Sever, contained a number of interesting exhibits. Mr. M. K. Eyre, of the Edison Lamp Works, exhibited a historical collection of incandescent lamps, showing the development of the lamp and its component parts, from the first crude forms to the present 220-volt, high-frequency lamp.

Mr. W. H. Meadowcroft exhibited a complete X-ray outfit in operation, as well as a variety of Röntgen ray tubes and fluoroscopes made by the General Electric Company. The Thomson inductorium employed gave a 14-inch spark, and was provided with the new hammer break.

Among other X-ray apparatus shown was a 20-inch spark coil and tubes, by Mr. M. O'Connor, who also showed a number of excellent X-ray photographs. Dr. Pupin showed an induction coil and circuit breaker, and Mr. M. Osterberg some German X-ray tubes and an electrical igniter for gas engines. Prof. R. O. Doremus exhibited one of the two original Henry induction coils. The Electric Arc Light Company showed one of their enclosed arc lamps in operation and various parts of the regulating mechanism. Among the battery exhibits was a small model of a Jacques carbon battery and the carbon cell used by Mr. W. E. Case in his lecture experiments before the New York Electrical Society. Both these were exhibited by the Electrical Engineering Department of Columbia University.

Messrs. C. M. Clark and C. W. MacMillen, senior students at Columbia University, exhibited in operation an apparatus devised by them for obtaining the maximum value of a direct current in any circuit and the time elapsing between the make and break of the circuit. They employ for this purpose a circuit breaker and the timing is done by a disc saturated with an iron solution and speeded at a known rate upon which the current leaves a trace. The Cutter circuit breaker employed, set at 40 amperes, broke the current in one-fiftieth of a second, the maximum current recorded on short circuit being 225 amperes.

There was also shown a 1-horse-power Fort Wayne self-starting synchronous motor, the construction of which is familiar to our readers. One of the insulators of the 10,000-volt Niagara-Buffalo transmission line was also on view.

In the Chemical Section there was quite an array of electric furnaces at work during the exhibition. Dr. R. O. Doremus, of the Department of Chemistry of the College of the City of New York, exhibited the electric furnace used by Prof. Moissan in his lecture before the Academy last fall. Another furnace was shown in operation by Messrs. Pellew, Tucker and Van Gelder, the quartz fused being condensed on a glass tube inserted in the top of the furnace. Mr. C. F. McKenna exhibited a "double arc" electric furnace. In this three carbons are used, placed at right angles, the two outer being connected to the positive and negative sides of a three-wire system, and the central carbon to the neutral conductor. Prof. Charles A. Doremus exhibited in operation an electric furnace arranged for lantern projection after a model of Roberts-Austen.

In the Physics Section Prof. O. N. Rood showed a set of photographs demonstrating the regular reflection of the X-rays, and Prof. C. C. Trowbridge two X-ray detectors or fluoroscopes of new form especially adapted to research. Prof. Wm. Hallock showed a hydraulic illustration of the Wheatstone bridge and a variable graphite-asbestos resistance, operating by pressure. Mr. H. C. Parker exhibited a set of graphite high resistances and a set of low resistance shunts. Mention must also be made of the electrical gyroscope of Prof. A. G. Compton which showed in an admirable manner the phenomenon of precession and other actions of the heavenly bodies.

INTERNATIONAL ITALIAN ELECTRICAL EXHIBITION OF 1898, AT TURIN.

On the occasion of the Italian National Exhibition, which will be held from April to October, 1898, to celebrate the Fiftieth Anniversary of the Proclamation of the Italian Constitution, exhibitors from all countries will be admitted to the special department of electricity.

The electrical exhibition will be divided into the following classes: 1. Equipment of electric and magnetic apparatus for schools. 2. Materials and fittings for electric wiring and distributing systems. 3. Electrical and magnetic testing apparatus. 4. Telegraphs and telephones. 5. Railway signalling and block apparatus; application of electricity to train lighting and heating. 6. Dynamo-electric machines and electric motors. 7. Mechanical applications of electricity—electric traction. 8. Electric lighting. 9. Electro-chemistry and electro metallurgy. 10. Miscellaneous applications of electricity. 11. Historical apparatus.

In issuing a general invitation to the electrical firms of all countries to participate in the Turin exhibition of 1898, the promoters are moved by the desire of presenting to visitors a complete display of exhibits from the best-known Italian and foreign manufacturers, including all the latest and most interesting inventions and improvements. The promoters are convinced that so far as electricity is concerned nothing but an exhibition where manufacturers and specialists of all countries are represented will prove efficient in assuring progress both in science and industry. Italy, where unemployed hydraulic power is still abundant, affords a large field to the enterprising spirit of electrical engineers. The success which crowned the International Electrical Exhibition held in Turin in 1884, where, besides many other practical results, the advantages of transformers were first brought into notice, justifies the hopes of the promoters that foreign electrical engineering firms will accept the invitation and take part in the exhibition of 1898, thus contributing with their specialties to make it a display worthy of this branch of industry.

The executive committee of the exhibition has appointed a representative of each nation to act as a member of the organization committee. Mr. J. W. Lieb, Jr., general manager of the Edison Electric Illuminating Company, of New York, has been appointed to represent the United States, and full information can be obtained from him.

LITERATURE

UNSERE KENNTNISSE IN DER ELEKTROLYSE UND ELEKTROSYNTHESE ORGANISCHER VERBINDUNGEN. (Our Knowledge of the Electrolysis and Electrosynthesis of Organic Compounds.) By Dr. Walter Loeb. Halle a. S., W. Knapp. 42 pp., 8 vo. Paper. Price, $1.50.

This work gives some interesting information on the progress of electro-chemical investigation in organic chemistry and describes a number of successfully executed electro-syntheses of organic compounds.

KALENDER FUR ELECTROCHEMIKER FUR 1897. With supplement. By Dr. A. Neuburger. Berlin, M. Krayn. 682 pp. Pocket size. Flexible covers. Price, $2.

This compact reference book gives besides the great mass of useful information, tables, formulas, etc., generally contained in such works, a great amount of specific information for the electro-chemist, which is not to be found in any larger work in so compact a form.

Besides the tabulated figures of the resistance and conductivity of solid, liquid or molten bodies, it furnishes calculations for the efficiency of electric central stations, directions for quantitative electro-chemical analysis, and a general treatise on secondary batteries. In connection with the latter it gives a tabulated review of nearly 70 pages of the capacity etc., of the secondary batteries in general use in Germany.

The supplement of 320 pages furnishes complete information as to the suitable arrangement of an electro-chemical laboratory, and a review of the patent laws, of most countries, laws and ordinances regulating the installation of boilers and electric power plants, insurance underwriters' rules, etc.

POCKET HANDBOOK OF USEFUL INFORMATION, PRICE LISTS, ETC.—By Joseph W. Marsh. Pittsburg, 1897. The Standard Underground Cable Co. 182 pp. Pocket size, with flap.

The long expected handbook of the Standard Underground Cable Company is now ready for distribution, and a careful investigation of the material contained between its covers will be time well spent.

The present edition contains 182 pages and is an amplification of the handbook published in 1890 with necessary additions to bring its contents up to date in every respect. From a perusal of the volume it is apparent that the purpose kept in mind in preparing this revised edition has been to give all useful information relating to electric wires and cables, and the installation of the latter, in as brief a form as possible consistent with a proper understanding of the subject discussed, and also to provide convenient rules, tables, etc., for ready reference and for use by practical men.

The first 110 pages contain the price lists of all material sold by the company, with complete descriptions of all such articles in detail, and a handy telegraph code for the use of customers.

The question of electrolysis is thoroughly discussed in an article by the company's electrician, giving the results of actual tests made in the laboratory and in actual commercial practice.

Complete instructions are given for installing all classes of cables and accessories, including conduit laying, cable laying and jointing, application of protective devices, etc. Methods of testing cables, locating faults, etc., are carefully discussed and explained with diagrammatic figures, and will prove valuable to those having such work to do.

The remainder of the book contains many tables of general and electrical information, among them complete data as to the diameter, weight and resistance of solid and stranded copper wire. These are especially accurate, and very complete.

The information on the "Effects of Alternating Currents," and "Changes of Electrical Properties with Change of Temperature," are of particular value at this time.

The general appearance of the book is very satisfactory by reason of the neat binding and the high grade of the typographical work. The volume will make a valuable addition to any technical library and its compact size renders it especially convenient for a pocket handbook.

PERSONAL

MR. N. W. PERRY has a careful historical and critical review of electric railway work in the April Cassier's Magazine, with many illustrations.

MR. G. H. STOCKBRIDGE begins in the April Engineering Magazine a series of articles on epoch making events in electricity. The first is on Volta and the electricity of tension succeeded by that of motion.

MR. A. A. CARY contributes to the Engineering Magazine another installment of his excellent article on boiler water and its purification. We are glad to note that Van Nostrand & Co. announce the appearance of these later in book form, from their house.

MR. ASHLEY W. COLE, recently appointed a member of the New York State Railroad Commission, has now been elected its chairman.

DR. S. S. WHEELER, president of the Crocker-Wheeler Electric Company, has returned from his March trip to Bermuda, fully restored in health.

MR. C. W. PRICE, editor of the Electrical Review, who went recently to the West Indies to shake off lingering traces of the grip, has returned home looking as though he had accomplished his purpose very successfully.

MR. MARTIN INSULL, of Sargent & Lundy, Chicago, has been in the East on professional work.

MR. G. F. NOXON, representing the Mayrhofer Electric Stage Lighting Company, has sailed for England, to put in the electrical effects for the play, "Shaft No. 2," which is to be produced at the Imperial Theatre, Newcastle.

MR. H. B. SWEET, lately of the Memphis (Tenn.) Electric Light and Power Company for some three years, has been appointed electrician for the Utica Electric Light Company, of Utica, N. Y.

MR. W. F. HAM has been appointed secretary of the Nassau Electric Railroad Company, of Brooklyn, N. Y.

COUNT ALEXANDER HADIK DE FUTAK, a gentleman hitherto unknown to fame, will, it is announced by the New York Press, "return to this city in June and go into business with Dr. Tesla."

MR. GARDINER C. SIMS, who has been staying at Lakewood, N. J., was in New York last week looking much better in health. He is still lame, however, from his accident.

LEGAL NOTES

INCANDESCENT LAMP LITIGATION.

The Westinghouse Company informs us that it has brought the following suits under its incandescent electric lamp patents against parties who have refused to take licenses: The Beacon Lamp Company, under the Stanley & Thompson patent, for process of manufacturing silk filaments; the Globe Electric Lamp Company, under the Weston tamadine or cellulose filament patent; the Warren Electric Specialty Company, under the Weston tamadine or cellulose filament patent; also under the Packard pump patent, and the Maxim patent for automatic cut-out used in the treating apparatus. The suit which was brought against the Davis Electrical Works is to be discontinued, as that company has now taken license.

MINNESOTA LICENSE LAW FOR ELECTRICIANS.

The substitute for H. F. 731, introduced by the committee on municipal legislation of the Minnesota Legislature, reads as follows:

Section 1. It shall be unlawful for any company, firm, corporation or individual, in a city of this State having a population of over 50,000 to install or repair any electrical wire or device for the transmission of electrical currents for arc or incandescent lighting, house annunciators, burglar alarms, telephone or telegraph systems, messenger call services, lighting fixtures, or other electrical apparatus, unless first licensed so to do by the city council of such city.

Sec. 2. The city councils of all such cities are hereby authorized and empowered to grant such licenses, and to require bonds from the licensees for the faithful performance of their duties.

Sec. 3. Any company, firm, corporation or individual who shall violate any of the provisions of this act shall be deemed guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not more than $500 or by imprisonment not more than six months in the discretion of the court.

SERVITUDE OF STREET RAILWAYS—A CONNECTICUT DECISION IN THEIR FAVOR.

THE Connecticut Supreme Court, after several months of deliberation, has decided the case of the Canastota Knife Company against the Newington Tramway Company, involving the question of the additional servitude of the trolley roads on highways as entitling the abutting landowner to damages. Two of the judges, Chief Justice Andrews and Judge Hamersly, hold unqualifiedly that the trolley road is an additional servitude. Three of the judges, Baldwin, Fenn, and Torrance, held in effect that the trolley road is not in itself an additional servitude but may become such by abuse. The effect of the decision, apparently, is to compel the landowner to prove such exceptional abuse before obtaining damages; and practically the decision seems a victory for the trolley companies, though the result is somewhat indecisive, and the main question was not squarely met by the court.

It is stated that the principle on which the court divided was the question of the priority of private rights on the Connecticut highways, the two judges who favored the trolley servitude, holding to the antecedent and fundamental character of such private rights, while the three other judges held that public and private rights are equal.

The question of the additional servitude has a number of times been raised during the last few years before the Supreme Court of Connecticut, but each time the decision has been evaded. The only previous decisions date back for about a third of a century. They are two in number. In the first the Supreme Court held that a steam road was an additional servitude on the highway, and in the second case a Supreme Court judge, sitting in a lower tribunal, denied the additional servitude of a horse railway. Up to the decision just rendered the Supreme Court of Connecticut has not passed, as a body, on the question of servitude in connection with a street railway.

THE ROOSEVELT TELEPHONE SWITCH PATENT DEFEATED.

Judge Grosscup, in the U. S. Circuit Court at Chicago, on April 5, decided against the Roosevelt patent, in the suit between the Western Telephone Construction Co. and the Western Electric Co., dismissing the bill of the latter company for want of equity. This patent, No. 215,837, was granted to H. L. Roosevelt May 27, 1879, and covered broadly the gravity switch telephone patents, viz., those in which the relations and conditions of the circuits are changed through the action of the weight of the receiver, when on its support, against a spring. The circuit is in one condition, open or closed, as the case may be, when the telephone has been taken off its hook, and in another condition when it has been hung up again. The patent had eight strong claims. The normal expiration of this patent is understood to have been May 27, 1896, but there are many others subsidiary to it.

WESTERN UNION TELEPHONE ROYALTIES IN THE U. S. SUPREME COURT.

At Washington, on April 12, the Supreme Court of the United States denied the petition for a writ of certiorari in the case of the American Bell Telephone Company vs. the Western Union Telegraph Company, to compel the Circuit Court of Appeals for the first circuit to certify the case to the Supreme Court. The case involves the question of royalties claimed from the Bell Company by the Western Union Company and was originally brought in the Circuit Court for the district of Massachusetts, to secure an account of these royalties. It is alleged that about $5,000,000 is involved, though that seems an extreme amount.

After instituting the suit the Western Union sought to have it dismissed, and after it was dismissed the Bell Company appealed to the Circuit Court of Appeals, when the decision of the Circuit Court was reversed.

The Western Union Company sought to have the case reviewed by the Supreme Court, but the opinion rendered denies this petition. This has the effect of taking the case back to the Circuit Court for further proceedings in accordance with the decision of the Circuit Court of Appeals.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 30, 1897.

Alarms and Signals:—

ELECTRICALLY CONTROLLED RAILWAY SIGNAL. F. McBrien, Newark, N. J., 579,929. Filed Sept. 3, 1896.

The signals are controlled by track circuits alone.

SIGNALING. J. G. Schreuder, Edgewood Park, and J. P. Coleman, Swissvale, Pa., 579,933. Filed Aug. 26, 1896.

Means whereby signals may be operated by operator or automatically by train movements.

Batteries, Primary:—

ELECTRICAL GENERATOR. S. V. Essick, Yonkers, N. Y., 579,707. Filed May 14, 1896.

For description see last issue.

BATTERY COVER. H. J. Brewer, New York, 579,916. Filed Oct. 2, 1896.

Means for removing the cover from the jar, and also for taking out a battery element which is supported by the cover.

Batteries, Secondary:

MOLD FOR MANUFACTURING SECONDARY BATTERY PLATES. F. King, London, England, 579,877. Filed April 10, 1896.

Details of construction.

Conductors, Conduits and Insulators:—

INSULATOR AND HOLDER FOR ELECTRIC RAILWAYS. W. C. Keithly, San Francisco, Cal., 579,725. Filed Nov. 27, 1896.

Means for securing the insulator within a protecting cap and removably locking it thereto, and suspending the whole device from the posts.

SUBWAY JUNCTION BOX. G. C. Deake and G. N. Moore, New York, 579,864. Filed June 30, 1896.

A subway box having an inner lower water-tight cover, loose top cover, and a duplex gas-relief valve in the lower cover, the valve adapted to first open a vent into a valve chamber, and later open the vent from the chamber.

Distribution:—

MULTIPLE SERIES SYSTEM OF ELECTRICAL DISTRIBUTION. —F. B. Badt, Chicago, Ill., 579,556. Filed Jan. 25, 1897.

Comprises a generator from which the main conductors only are led, and electromagnetic means adapted to respond upon'a variation in potential between a compensating and a main conductor to reduce the electromotive force of the generator.

Electro-Metallurgy:—

APPARATUS FOR HEATING BLOOMS OR OTHER ARTICLES OF METAL. A. J. Moxham, Johnstown, Pa., 579,597. Filed Nov. 4, 1890.

Consists in directly surrounding the article to be treated by a conductor adapted to carry the electric current.

PROCESS OF TREATING AURIFEROUS AND ARGENTIFEROUS ORES. J. H. Haycraft, Adelaide, South Australia, 579,872. Filed Sept. 29, 1894.

Process of extracting gold and silver from finely divided auriferous and argentiferous ores.

Measurement:

ELECTRIC METER. G. Hookham, Birmingham, England, 579,582. Filed Sept. 18, 1896.

For continuous currents.

Miscellaneous:—

METHOD OF OVERCOMING ELECTRIC PHENOMENA IN GOODS, ETC. B. W. Child, Boston, Mass., 579,738. Filed July 26, 1893.

Means for rendering normal the electric condition of paper, consisting in directing upon it a current of atmospheric air and bringing into close proximity with the surface of the material, electric conductors.

ELECTRICAL GOVERNOR FOR MARINE ENGINES. G. A. Tower, Richmond, Va., 579,780. Filed March 18, 1896.

Details of construction.

MOTOR PROPELLED VEHICLE. H. G. Morris and P. G. Salom, Philadelphia, Pa., 579,890. Filed June 20, 1896.

Employs two electric motors so mounted side by side on the axle that the two driving wheels are independently driven.

ELECTRIC HEATER. W. R. Smith, Manchester, N. H., 579,611. Filed June 11, 1896.

Employs an electrical resistance composed of a single jointless piece disposed in two helices of opposite pitch.

REFLECTOR FOR FOCUSING CATHODE RAYS. R. M. Russell, Birmingham, Ala., 579,808. Filed Sept. 15, 1896.

Consists of the outer concavo-convex shell of lead and an inner shell of tin.

Railways and Appliances:—

TROLLEY WHEEL FRAME FOR TROLLEY CARS. W. Grunow, Jr., Bridgeport, Conn., 579,576. Filed May 8, 1896.

A tangential trolley wheel frame adapted to be connected with the trucks of a car.

TROLLEY SYSTEM. W. H. Walker, Pittsburg, Pa., 579,728. Filed June 26, 1896.

Details of construction.

ELECTRIC RAILWAY. F. Mansfield, New York, 579,759. Filed Aug. 4, 1893.

Comprises a car having double trucks, a contact device suspended therefrom, consisting of a short conducting bar supported horizontally beneath and between the axles of each truck, and an intermediate conducting bar hinged between the short bars.

ELECTRIC RAILWAY. F. Mansfield, Philadelphia, Pa., 579,760. Filed Aug. 13, 1895.

Contact device for third-rail system.

Switches, Cut-Outs, Etc.:—

SWITCH BOX FOR FLUSH SWITCHES. J. W. Poole, Chelsea, Mass., 579,894. Filed Dec. 28, 1895.

Details of construction.

Telegraphs:—

TELEGRAPH TRANSMITTER. C. L. Buckingham, New York, and J. Gardam, Brooklyn, N. Y., 579,633. Filed Sept. 2, 1896.

Comprises a motor, a train of gear, circuit controlling apparatus for directing suitable signals to line, a phonic governor, consisting of a toothed wheel connected to and driven by the train of gear, and a tuning fork spring, whose vibration is maintained by the teeth of the wheel.

PRINTING TELEGRAPH. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 579,634. Filed Aug. 28, 1896.

Comprises a stationary support having circumferential grooves, inclined grooves, gear wheel, feed wheel, an escapement wheel and a train of gearing for positively connecting the wheels togther.

PRINTING TELEGRAPH. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 579,635. Filed Sept. 3, 1896.

Similar to above.

PRINTING TELEGRAPH. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 579,635. Filed Sept. 3, 1896.

Similar to above.

PRINTING TELEGRAPH. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 579,636. Filed Jan. 5, 1897.

Similar to above.

STOCK PRINTER. F. A. Graham, New York, 579,676. Filed March 11, 1896.

Comprises a single belt provided with printing characters, a series of paper strips, and electromagnetic mechanism for causing an impression to be made upon any one of the series of strips.

Telephones:—

MICROPHONE. A. W. S. Davis, Lowell, Mass., 579,699. Filed April 30, 1896.

Consists of a casing having a central aperture and a transverse groove, and a diaphragm, a button, an adusting screw for the button and a covered flat spring lying in the groove, for supporting tthe button.

MOUTHPIECE FOR TELEPHONES. C. L. Cohn, Boston, Mass., and M. Martin, Malden, Mass., 579,790. Filed Dec. 11, 1896.

Embodies a frusto-conical mouthpiece lining, comprising a liquid-proof external section, and an absorbent inner section secured to the interior of the outer section.

THE STOCK MARKET

LITTLE ADVANCE IN THE BUSINESS SITUATION.

Plague in Asia, war in Europe and floods in America present a trinity of adverse conditions, and the need of a Mark Tapley spirit is much manifest in these days. Still, things in trade and industry do hold their own with remarkable firmness. Business failures remain at the lower level already noted, bank clearings show a gain of 20 per cent. over the corresponding week in 1896, and gross railway earnings are larger for the first time since July last year. Seeing that tariff uncertainty ties up many wheels, this is an obviously good retrun.

Western Union on sales of 19,025 shares rose from 79¾ to 81½; and General Electric on sales of only 2,100 hovered around 31 and 32. American Bell Telephone declined from 222 to 218½.

REPORTS OF COMPANIES

GENERAL ELECTRIC BALANCE SHEET.

The General Electric Company has filed this abridged balance sheet as of Jan. 31, 1897:

ASSETS.	
Buildings	$444,437
Cash and debts receivable	10,176,755
Merchandise, etc.	3,988,757
Patent rights	8,000,000
Debenture in treasury	512,132
Miscellaneous	11,787,681
Profit and loss deficit	12,697,685
Total	$47,607,448
LIABILITIES.	
Capital stock	$34,712,000
Debts and reserve	12,895,448
Total	$47,607,448

The General Electric's profit and loss deficit of $12,697,685 compares with $13,917,071 Jan. 31, 1896; $14,794,716 in 1895, and $12,454,967 in 1894.

TRADE NOTES & NOVELTIES

THE NEW POWER WHEEL—THE CAZIN WATER AND STEAM WHEEL.

THE subject of the utilization of water power, which is becoming of such importance, and which might be said to be still in its infancy, so far as this country is concerned, has received additional matter in the shape of a pamphlet just distributed among civil, mechanical, and electrical engineers, generally throughout the United States, by the American Impulse-Wheel Company of New York.

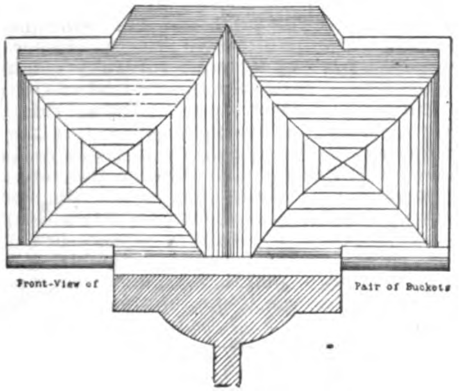


FIG. 1.

The invention described in the publication referred to, is a wheel of the free jet or percussion type (operated by either steam or water) which is claimed to go beyond anything of the sort hitherto known to the mechanical world, in developing maximum efficiency of the motive power.

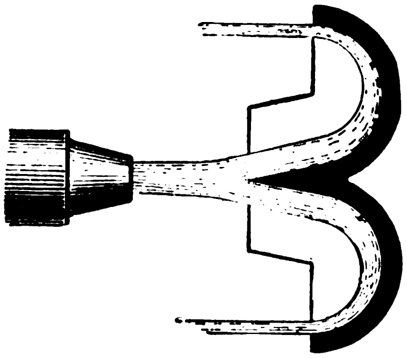

FIG. 2.

It is an established fact in hydraulics that the jet of water must be completely inverted by the vane or bucket of a wheel, traveling at half the velocity of the jet, in order to obtain the best results in transmitting the inherent power of the jet. It is unnecessary to quote authorities in support of this theorem, but it is of interest to note the claims of this new wheel company in complying therewith. The accompanying engravings indicate more clearly than verbal explanations the basis for the assertion, that the wheel actually performs the work theoretically required.

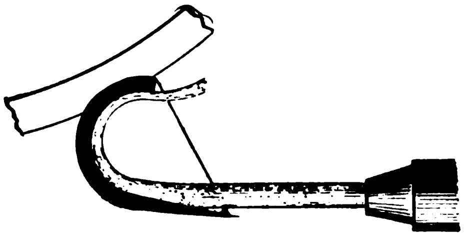

FIG. 3.

Fig. 1 shows a front view of a pair of buckets in which the curves of the receiving lip and vanes are indicated by the shaded lines.

Figs. 2, 3 and 4 show sections of the vanes showing not only the true curves but also the course of the jet in contact therewith.

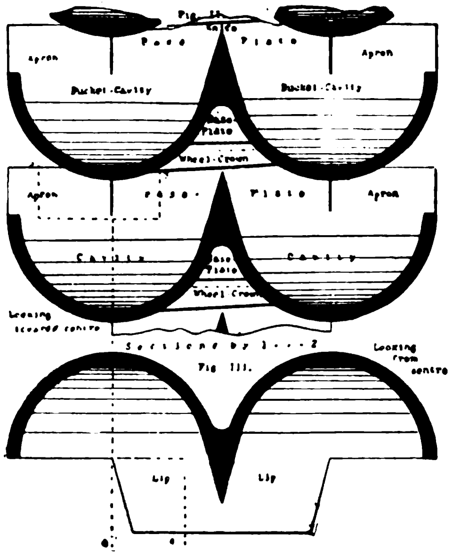

FIG. 4.

Fig. 5 finally shows the positions of the vanes on the wheel crown and also the diagonal nozzle tip intended to provide against loss of power between the time the jet leaves the nozzle and contact with the buckets.

These diagrams show the pertinent facts of the merits of the device, and it is claimed and demonstrated, in the pamphlet referred to, that the jet is not only inverted while the bucket is in its best positon relative to the jet, but also completely and permanently in all positions taken by the bucket while receiving the jet impact—a necessary condition to highest efficiency frequently overlooked by wheel manufacturers. In addition to these brief items, the book contains considerable information relating to power calculations, hydraulics, water rights and other matters, part of which has appeared in the Journal of the Franklin Institute and various engineering publications. The invention is covered by patent rights issued to F. M. F. Cazin, inventor, and is offered for sale by the American Impulse-Wheel Company, 120-122 Liberty street, New York, who will furnish copies of the book upon application.

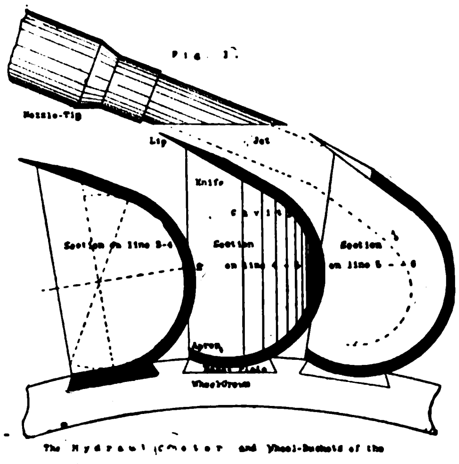

FIG. 5.

A CORRECTION.—An error was made in our notice of a pole sale made by S. C. Strock, New York, to the American Telephone and Telegraph Company. Instead of 3,000 poles, Mr. Strock informs us that the sale comprised no fewer than 8,000 poles, and that the lengths were from 25 to 55 feet. This in itself makes the transaction a decided record breaker in manufactured yellow pine poles. If a larger order has been given lately, we would like to note it.

THE NEW YORK DYNAMO AND MOTOR CO.

This active young concern, under the management of the enterprising Mr. A. Farina, has secured the New York agency of Messrs. Roth Bros. & Company, of Chicago, who manufacture a complete line of motors, dynamos and fan outfits. The fan motors are well designed, mechanically and electrically. The fields are of wrought iron and all parts of the field and armature coils are readily accessible. The bearings are self-oiling and do not "throw" or drip oil.

The company make a specialty of designing isolated plants for private installations for city or country use. The offices of the New York Dynamo and Motor Company are at 257 Broadway.

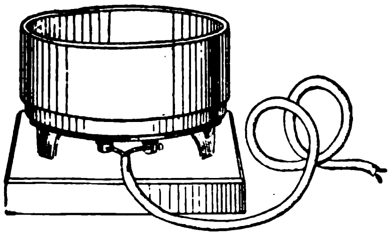
COLUMBIA INCANDESCENT LAMPS.

IT gives us pleasure to announce that Mr. R. B. Corey has recently taken charge of the sale of the Columbia incandescent lamp in the eastern territory, in addition to his other electrical lines, with offices in the Havermeyer Building, New York. Mr. Oscar Hoppe, New York manager of the Columbia Company during the past year, is associated with Mr. Corey.

The Columbia Company have just issued a circular describing their different styles of street railway lamps. A feature of their new railway lamp is the double coil filament without an anchor. Practice has shown that the filament in this lamp does not droop and come in contact with the glass, and that the lamps give very satisfactory service and a beautiful light.

The company also manufacture a round bulb lamp which is now in extensive use on street railways, for head lights. This lamp consumes the same amount of energy as the lamps in the cars, so that it can be used in series with them. This lamp is also admirably adapted for decorative illumination in cars used by trolley parties. It is furnished either plain, frosted, or colored. The bulb of this lamp is round and a trifle over two inches in diameter, setting directly into the base, without a neck. This construction gives it great strength and compactness.

ELECTRIC SOLDERING POTS.



The American Electric Heating Corporation, of Boston, announce as ready for market electric solder pots in two sizes, one to hold four pounds using 1¾ amperes at 110 volts; a larger size holds ten pounds. They are easily portable and are by far the best device for this work ever offered. It is clear that neither gas nor gasoline heated pots can compare with them for cleanliness, convenience or close regulation of temperature. These pots are especially useful in electrical repair shops for tinning wire and similar uses. They are fully guaranteed.

FERRACUTE DIES AND PRESSES FOR ASIA,

A remarkable example of the promptness with which many branches of American industry are capable of responding to the new developments in export trade is afforded in the factory of the Ferracute Machine Company, of Bridgeton, N. J. A few days ago, a number of the officials of the Philadelphia mint, and other engineering experts, were invited by Mr. Oberlin Smith, the president and engineer of the company, to inspect a notable consignment of presses, dies and other apparatus which have been ordered by an Asiatic government. This machinery is intended to supersede European appliances, which have hitherto been the only ones virtually available. The foreign trade of which this order is a noteworthy evidence, has sprung up within the last twelve months, during which the Ferracute Company has received commissions from many distant corporations, mostly in Europe. The specialty of this company is cutting, stamping, embossing and coining presses. It is now doing a great deal of electrical work. Among its recent orders were a number of presses for stamping armature plates, for the General Electric Company. Similar presses have been sent to Berlin and Buda-Pesth. Some of these presses weigh 15,000 or 16,000 pounds. The larger sizes are capable of stamping armature plates of five and six feet diameter. All these machines have been designed by Mr. Oberlin Smith, whose name, for many years, has been a household word in engineering circles. Bridgeton, where the works of the Ferracute Machine Company are located, is a lively manufacturing city of some 13,000 inhabitants, in the "wilds" of New Jersey, 38 miles south of Philadelphia.

FOSTORIA INCANDESCENT LAMP CO.

The announcement was made recently of the formation of the Fostoria, O., Incandescent Lamp Company. The capital is $50,000, all of which is paid in by the subscribers. The directors are: J. B. Crouse, Rosswell Crocker, H. A. Tremaine, B. G. Tremainé, and Ira Cadwallader, each of whom subscribed for $10,000 of stock. The officers are: J. B. Crouse, president; Rosswell Crocker, vice-president; H. A. Tremaine, secretary and treasurer. It will be noted that the men prominent in the enterprise are those so well known in connection with the Crouse-Tremaine Carbon Company, the manufacturers of electric light and other carbons at Fostoria.

THE PAINT FOR 1897.

Prof. Spennhath, Director of the Technical School of Aix-la-Chapelle, lately won the $2,000 prize offered by the Society for the Advancement of the Industrial Arts for the best essay on Protective Paints. The prize was not won simply by theoretical demonstrations, although the professor furnished scientific reasons also, but by most carefully conducted practical experiments with various pigments and oils, covering several years' time. The results demonstrated that a properly made paint of graphite and boiled linseed oil is the most suitable for protecting structural iron work, roofs, etc., exposed to the destructive agencies of heat, cold, storms, etc.

Running parallel with these results are the facts demonstrated by those who have used Dixon's Silica Graphite Paint during the past 30 years. Roofs and iron work properly painted with Dixon's paint have not required repainting in 15 to 20 years. As the season for painting is now close at hand it may pay those interested to write to the Joseph Dixon Crucible Company, Jersey City, N. J., for circulars.

ENCLOSED ARCS IN FRANCE.

The United States has always held a high place in the world's record of practical inventions, and the success of the enclosed arc lamp here, followed by its adoption in France after the lecture of Prof. Louis B. Marks, before the Société Internationale des Electriciens in Paris, on January 20, 1897, is another feather in the eagle's wing of ingenuity and progress. We understand that whilst at first the new system was viewed with incredulity and indifference, a total change came over th French scientific world after the explanations and demonsrations of the lecture above referred to, which has appeared in full in our columns. We congratulate Mr. Marks on his phenomenal success.

CASTINGS FOR THE BERLIN, CONN., POWER PLANT.

The Sessions Foundry Company, Bristol, Conn., have recently made nearly all the castings for two large engines for the Berlin power house for running cars by electricity on the steam railroad track from New Britain to Hartford and other points; and among the other castings were two heavy balance wheels weighing complete and finished 50 tons each. The Sessions Company cast each wheel in two sections, making each casting about 26 tons each; and they have facilities for making even larger castings than that.

NEW RAILS FOR THE B. & O.

The recent purchase of 58,000 tons of 80 lb. steel rails by the receivers of the Baltimore and Ohio Railroad Co. at a cost of about $1,000,000 is another evidence that Messrs. Cowen and Murray intend placing the B. & O. in first-class physical condition. It is understood that these rails will be placed in the track as soon as possible, and that by fall the tracks between Baltimore and the Ohio River will practically be entirely relaid with new steel and new oak ties. As fast as the old rail is taken up it will be relaid on the less important branches, or used in extending much needed side tracks.

LALLY'S ELECTRIC LIGHTER FOR FIRE ENGINES.

John T. Lally, of Wilmington, Del., has invented an electric lighter which has been placed in the engine house of the Reliance Fire Company. The lighter is fastened to the floor about 18 inches in front of the engine and as the engine strikes the lever the electric spark lights the gas which throws a flame to the height of 14 inches and about 4 inches in width, so as to light the kindling in the engine. There is no waste of gas. The arrangement is very complete. The lighter and the box that contains the springs which open and close the valves controlling the supply of gas are handsomely nickel-plated.

THE BANGOR ELECTRIC CLOCK COMPANY is being organized at Bangor, Me., with Gen. Joseph S. Smith as general manager. One of its clocks is the invention of W. J Dudley and is said to run three years without attention.

NEW YORK NOTES.

AMERICAN WAX AND PAPER COMPANY, 199 Franklin street, New York, have recently received two carloads of pure ozokerite which they are now offering to the electrical trade at reasonable figures.

BAYSHORE, L. I., is to have an entirely new electric lighting plant. Messrs. Osterberg & Sutton, who are the consulting engineers for the company, have sent out plans and specifications. The 2,000 volt single phase system will be used, and the streets of Bay Shore will be lighted up by about May 15 for the first time in several years.

MR. T. E. HUGHES will hereafter represent in New York the wire department of the Standard Underground Cable Co., as distinguished from its cable business, the growth of its trade necessitating bifurcation. Mr. G. L. Wiley informs us that April 20 the company will move to Rooms 506-8-10, in the Telephone Building, 18 Cortlandt street.

THE STANDARD OIL COMPANY are about to erect at Bayonne, N. J., a boiler shop 300 feet long and 105 feet wide. The main portion of the shop is divided into three bays. The central bay, about 50 feet wide, is served with a 15-ton electric crane supported on heavy girders about 40 feet above the floor. On either side of this main portion is a wing about 30 feet wide. The walls of the building are brick and the supporting frame work is steel. The roofs are to be covered with corrugated iron. The main columns of the shop are 25 feet apart and all arranged so that jib cranes of suitable size and capacity can be attached at any point, which, together with the traveling crane in the center, will enable them to cover the entire floor surface of the building. One end of the building for a distance of about 75 feet in length is supported by clear span trusses which gives a clear floor space over this entire area. The steel work was designed and will be erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

THE CONDUIT WIRING CO., 12 West Twenty-ninth street, has gone out of business and has transferred its operations to Davis & Brussel.

ELECTRIC CARRIAGE AND WAGON COMPANY is now licensed to operate twelve storage cabs and hansoms, and now has six in service. Its stables are in West Thirty-ninth street, off Broadway.

THE IMPERIAL ELECTRIC COMPANY, 140 Washington street, and the M. & M. Co., of same address, have combined their interests. The business will be continued under the firm name of the Imperial Electric Company.

J. W. FERGUSON, 253 Broadway, general contractor, is building the new plant of the Edison Electric Illuminating Company, of Brooklyn. The foundation is already started and, it is expected, will be completed by him about August 1. This plant is to be the main station of the company on Long Island. Mr. Ferguson has been identified for a number of years in the electrical trade as a general contractor for the building of power plants, factories, mills, shops, etc. A few of the plants built by him are the Edison Electric Illuminating Company, Paterson, N. J.; the Bergen County Traction Company, Fort Lee, N. J.; the Steinway Railway Company, Astoria, L. I.

JAMES L. ROBERTSON & SONS, 204 Fulton street, New York, have brought out a new edition of their excellent catalogue as to their Robertson-Thompson indicators, and other instruments. It also includes descriptions illustrated and in detail as to their Hine eliminator, Robertson pump governor, live steam separator, exhaust oil extractor, shaking and dumping grate bars, exhaust pipe head, waste oil filter, Kellam's steam damper regulator, safety water columns, and other necessary apparatus for central stations and isolated plants. It is a very useful catalogue for all steam users to have around the house.

CLIMAX BOILERS.—The Clonbrock Steam Boiler Company, Brooklyn, N. Y., have issued an admirable catalogue in regard to their boiler. It is in effect a handsome book and a manual of steam data, full of useful information, and contains in addition a number of views and other details illustrative of the numerous electrical and other plants in which their celebrated vertical boilers have been installed. A copy will be sent to any address on application.

ELMER P. MORRIS has removed his office to the Smith building, 15 Cortlandt street, New York, where he will be pleased to see his friends. Mr. Morris is manufacturers' agent for several well-known concerns and is in excellent shape to furnish at short notice anything in the line of arc lamps, measuring instruments, railway specialties, and general electric supplies.

WESTERN NOTES

THE ELECTRIC APPLIANCE COMPANY report that they are rapidly closing agency arrangements in different parts of the country for their 1897 line of fan motors and ceiling fans. They are offering a full line of direct and alternating fan motors, and also a full line of direct and alternating current ceiling fans, and are prepared to offer attractive arrangements to good live agents.

THE CENTRAL ELECTRIC COMPANY is carrying in its Chicago stock a complete line of snap, flush and push switches of the following makes: Hart, Perkins, Xntric, Stevens and C. S., and is prepared to furnish these goods made up in gangs with any particular finish, to match special hardware. This company is publishing a four-page folder price list of the Stevens push button switches, which it states will be gladly mailed to any one in the business, upon receipt of a communication requesting the same.

WEBSTER CHEMICAL COMPANY, 400 Sibley street, St. Paul, Minn., are selling a crystal chemical coloring for incandescent lamps, which costs but little and of which the users speak in the highest terms. One pint will color 300 lamps and give them a brilliant, durable, clear color. They will be glad to hear from those who need colors of any hue.

J. H. SIEGRIST, JR. COMPANY, 13 Laclede Building, St. Louis, who have placed 197 of the "Ideal" automatic engines in St. Louis, have now taken the agency for the new "National" electric apparatus, both alternating and direct current, direct connected and belted to handle in connection with the above engines. As a "starter," they have sold a 50-kilowatt "National" direct connected generator and 13-in. x 12-in. "Ideal" engine to the Koken Iron Works, St. Louis, to be used for running motors on the machine tools to be installed in their new shops. The above company have been in the engine business since 1886, and are well and favorably known among the prominent steam users of the West.

THE METROPOLITAN ELECTRIC COMPANY are sending out to the trade a comprehensive catalogue covering electrical and combination fixtures which they manufacture. This catalogue is complete in every detail, and a great many of the fixtures are now shown to the public for the first time.

THE WESTERN ELECTRIC COMPANY have just issued an illustrated booklet of their various types of 1897 fan motors. The matter is very descriptive; full details of the different styles of fans which they manufacture, are given as well as the prices. This little book is gotten up in a most tasteful manner with a green paper cover on which is shown a cut of one of their newest desk fans printed in gold relief. The interior is also a very creditable specimen of the printer's art, the reading matter being set up in red and black type; and the handsome half-tone cuts which are also shown serve to add to the attractive appearance, and usefulness of the publication.

AMERICAN ELECTRIC TELEPHONE COMPANY, hitherto of Kokomo, Ind., should now be addressed at 171-173 South Canal street, Chicago, where they have now established their office and factory with increased facilities and first-class modern appointments.

KINLOCH TELEPHONE COMPANY, St. Louis, Mo., claims to have 4,000 prospective subscribers under contract and is now busily engaged laying its conduits.

CHAS. E. GREGORY COMPANY, Chicago, announce that owing to the constant increase of work in their repair department, they found it necessary to have larger space, and have secured commodious quarters at 47-53 South Jefferson street, beside their old stand, where they have an equipment suitable for turning out work promptly. The additional space which has been acquired will supply a long-needed want of room for suitably displaying and handling their large stock of machinery, apparatus and general electrical goods.

THE GARTON-DANIELS ELECTRIC COMPANY, Keokuk, Iowa, report that business has begun picking up with springlike activity and sales for the first three months of this year are over double those of last year. Orders are coming in from all parts of the United States, as well as from foreign countries. Many of the largest street railways and central stations, have adopted Garton arresters and will use no other. The company consider prospects as brighter than ever before, and very encouraging for a steady good trade.

THE DEARBORN ELECTRIC COMPANY, Chicago, have removed from their old quarters at 19 Quincy street, to 330 Dearborn street, where they have fitted up a very nice office and store. Since the reorganization of this company a few months ago, and the infusion of new blood into the concern in the persons of Messrs. Charles Messer and A. W. Dee, the business of the concern has shown quite a healthy increase, and its energetic managers are very hopeful of being able to secure a good share of the electrical supply trade in the near future. They report that they have had some very nice orders for Dearborn long-distance telephones, in addition to regular electical supplies. This company has also got the agency for New England switches, which are meeting with considerable favor in the Western territory.

PHILADELPHIA NOTES

A. W. FRANCE, Tacony, Pa., reports having received an order from Sayre & Fisher Co., Sayreville, N. J., for a large alternating and 500-volt direct current switchboard, to be equipped with his patent non-arcing switches; also one from the Suburban Electric Company of Tacony, Philadelphia, for an 8-circuit board for the 2,200-volt alternators to be equipped with non-arcing switches. The Suburban Company made a very thorough test with these switches before placing their order, shifting very heavy loads from one machine to another, without a sign of an arc. They have pulled the switches on dead short circuits without a spark. He is also very busy filling orders for fuse boxes and grease cups, the demand being so great that the factory is kept running day and night.

PHOSPHOR-BRONZE SMELTING COMPANY, LTD., 2200 Washington avenue, Philadelphia, have issued a new brochure with regard to their excellent Delta metal, an alloy of copper, made in various relations of combined qualities in adjustment to the demands of different characters of work. There are many uses for it in the electrical field.

THE SAWYER ELECTRIC COMPANY, Lippincott building, Philadelphia, have taken the agency for Eastern Pennsylvania of the Royal alternator, built by the Royal Electric Company of Peoria, Ill.

CUTTER ELECTRIC AND MFG. CO., of Philadelphia, have appointed Mr. A. D. Chandler, of 1114 the Marquette Building, Chicago, Western agent for their well-known make of switches and circuit breakers. Mr. H. B. Cutter, president of the company, made quite a prolonged visit to Chicago while completing the new arrangements for conducting the Western agency of his company, and at the same time had an opportunity of meeting some of his many friends who reside in that city.

KEYSTONE ELECTRIC INSULATION COMPANY, of Philadelphia, find that they are enjoying a large increase of business in New York City and need better facilities in that region. They have therefore secured a suite of offices in the Smith Building, 15 Cortlandt street, where they will be glad to see friends and show samples. Their interests at that place will be represented by the ever energetic Elmer P. Morris.

NEW ENGLAND NOTES

THE BOSTON ELECTRODUCT COMPANY is, it is stated, building a new factory at Versailles, near Pittsburg. The main building will be 122 by 43 feet.

NATIONAL RUBBER COMPANY, Bristol, R. I., request that in future all communications in regard to general office business be addressed to W. De F. Brown, secretary, Bristol, R. I.

ADVERTISERS' HINTS

THE WARD LEONARD ELECTRIC COMPANY, Hoboken, N. J., offer to send on trial (they paying expressage both ways) one of their new type motor-starting rheostats to those requesting it before May 1.

A. L. BOGART, 22 Union Square, New York, advertises frictional machines and a full line of gas lighting supplies.

THE STANLEY ELECTRIC MANUFACTURING COMPANY have removed their Chicago office from 305 Dearborn street, to 1506 Marquette Building, where they will be glad to take care of the Western trade as of old.

THE BURT MANUFACTURING COMPANY, Akron, O., agree to send any prospective buyer one of the Cross oil filters for thirty days' trial in order that it may prove it saves 50 per cent. And if it does not prove it, it may be returned at the company's expense.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., have experienced such a demand for their apparatus as to necessitate running their works day and night.

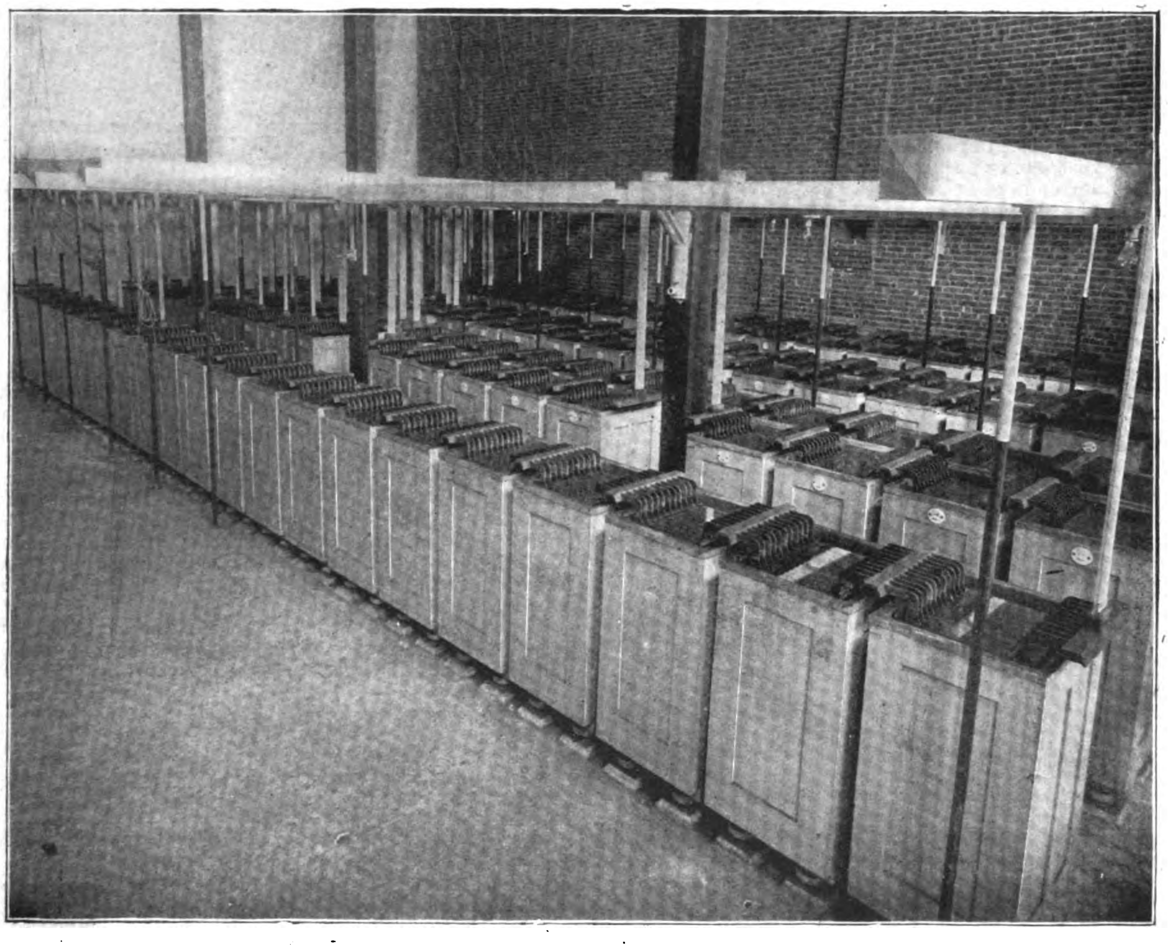
ELECTRIC LIGHTING

THE SCOTIA STREET STORAGE BATTERY STATION OF THE BOSTON EDISON CO.

THE Edison Illuminating Company, of Boston, were one of the very first companies in the United States to install storage batteries as auxiliaries to their generating plant; and to their two battery plants which have been operating for the past few years they have now added a third plant. This latter, known as the Fourth or Scotia street station, is distinguished from its predecessors in that it is purely a battery station and has no generators.



Battery Room in Scotia Street Storage Battery Station, Edison Electric Illuminating Co., Boston, Mass.

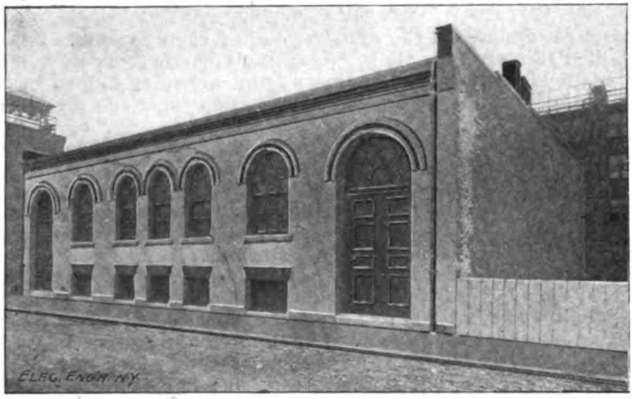
The problem which presented itself was that of supplying light and power two miles from the nearest generating plant. The district supplied by the Fourth station is the Back Bay or fashionable residence district of Boston. It was, of course, impracticable to put in a steam plant in such a district, to say nothing of the poor economy which such a plant would give. The company had been refusing to supply power in the district for several years, because of the variation which it caused in the lights, being so far from the generating station. They also had the problem of extending their system in order to take in customers who were constantly applying for light. The district seemed too far from the generating plant to run new feeders, so that it was finally decided that a storage battery plant would solve the problem in the most satisfactory way, as this would enable the company to take light and power customers on the extreme end of their system. It also enabled them to take their generating current from their most economical station on the water front and also helped to improve the economy of that station by increasing the night load on it.

After deciding upon the battery plant, and foreseeing that this would be the probable future means of extending the system, it was determined to put up a battery plant thoroughly equipped to give the best possible results, but to be put up at a reasonable expense, with a view of determining what would be the cost of constructing such stations.

The station is located a little to one side of the Back Bay district and is 7,000 feet from the First or Head Place station, which, in turn, is 3,800 feet from the Third or Atlantic avenue station on the water front. The Fourth station is, therefore, a trifle over two miles from the generators which charge the battery. The current is sent from the Third station to the First and from there to the Fourth, being generated at a high potential, the same generator charging the First station battery as well as the Fourth and the current being boosted to make up for the drop in potential between the First and the Fourth stations.

The building is of brick, quite plain, covering an area of 60 by 65 feet, the roof being about 25 feet above the floor. The walls are 20 inches thick, so that the building can be run up to any height desired in case a use should develop for upper stories in the shape of apartments or a store house. The roof is placed at such a height that iron work for two more floors can be put in under it. As the battery only takes up half of the space it is possible, by putting in an extra floor, to install a battery of four times the present capacity.

The front of the building is divided off into a room about 12 feet wide and the full width of the building, which is used as a regulating room, the battery occupying the other portion of the building. There are three monitors in the roof for ventilation and there are also three ventilating ducts in each of the side walls. The floor is composed of 12 inches of concrete, with a regular cement finish, it being the company's experience that it is unnecessary to make a battery room floor so that it can be flooded with acid or water, it being a very simple matter to keep acid off the floor.

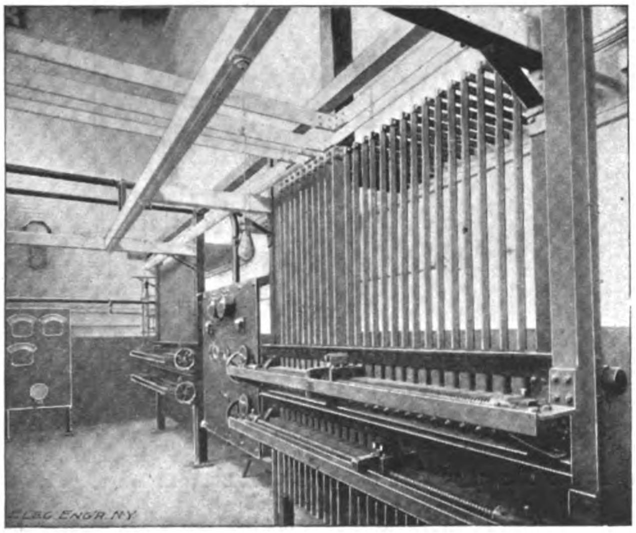


THE SCOTIA STREET STORAGE BATTERY STATION, BOSTON, MASS.

Each cell sets on four petticoat insulators, resting on tiles 6 x 6 inches, bedded in cement on the floor. The battery consists of 140 cells, each consisting of a hard pine tank, 18 x 22 x 38¾ inches, inside measurement, lined with 5-pound lead. The tanks are of ample size to allow plenty of room on both sides of the plates. In each cell there are 10 Manchester positive plates and 11 chloride negative plates. Of the 140 cells, 70 are on each side of the three-wire system. Of the 70, 24 are connected to the regulating switches. The discharge rate of the battery, which was installed by the Electric Storage Battery Co., is as follows:

Rate of Discharge. Amperes.	Capacity of Each Cell. Ampere Hours.
400	3,000
560	2,630
800	2,250
1.600	1,500

The regulating cells are connected to the regulating switches by 3 x ½ inch and 1½ x ½ inch drawn copper bar. The bars are supported on porcelain insulators resting on wooden hangers. The latter are supported from the floor by iron pipes, but so arranged that when the intermediate story is put in, the bars will be supported from the ceiling. There are at present two regulating switches in multiple on each side of the system, so that the batteries can be discharged at two pressures at the same time. The bars, however, are so arranged that two more regulating switches can be put on each side, giving a possibility of discharging at four different pressures. The regulating switches are operated by hand.

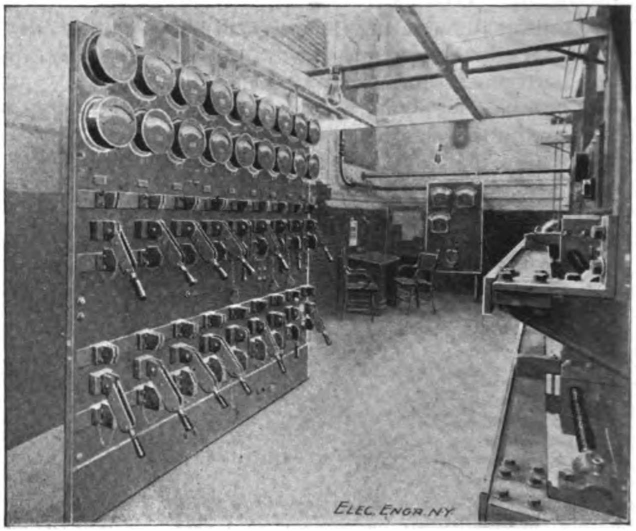


THE CELL REGULATING SWITCHES.

Immediately opposite the regulating switches is the feeder board, which has two brushes on each side of the system, and to the apparatus and feeders are connected two double-throw switches, thus permitting of the connection of any of them to either bus. This switchboard is equipped with round pattern Weston ammeters with composition shunts. The switchboard is of slate, and quite plain.

Between the two regulating switches is a slate regulating board about five feet square, upon which are mounted two Weston round pattern galvanometers with plug switches, two Weston portable voltmeters, reading to three volts, connected to the two circular cell switches, the latter being connected to the 24 regulating cells on each side of the system. On this switchboard are also mounted two booster field regulators.

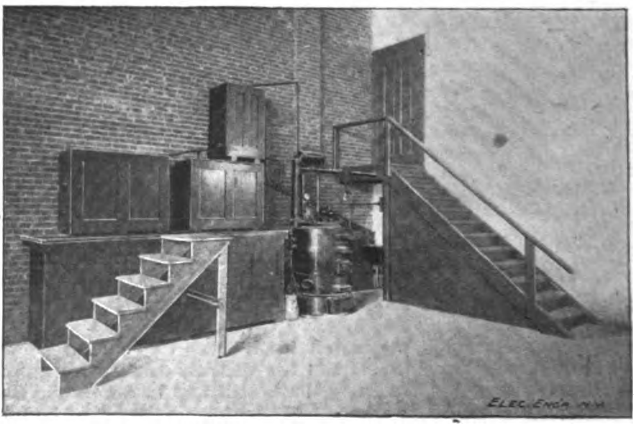
At the end of the room and at right angles to the feeder board and the regulating board is a slate indicator board, on which are mounted four Weston illuminated dial volt meters, a pressure testing switch, connected with all the feeders and busses in the station, and a Bristol recording voltmeter. On the back of this board is a switch controlling the disconnective junction box.



THE MAIN BATTERY SWITCHBOARD.

The booster set in this station is made of four 60 k. w. Edison bi-polar dynamos, the booster armatures having been rewound. On the neutral end of the battery there is an Aron meter on each side of the system and also a single-throw knife blade switch. The cables connecting the various switchboards and the feeder switchboard with the street are run in iron-armored conduit.

The fourth station is connected to the first by a one million circular mils cable feeder, which meets two of the old feeders supplying the district from the first station. At the junction of the new tie line with the old feeders there is a disconnective junction box, so that it is possible to disconnect the outer end of the feeders and make them a portion of the tie line or to supply the feeder ends from the first station or the fourth station, as may be desired. It is also possible, by the use of a booster at the first station to run these feeders from the



THE WATER STILL, SCOTIA STREET STORAGE BATTERY STATION, BOSTON, MASS.

fourth station and at the same time send current back to the first station to help over the maximum load.

Thus far, the working of the station has fulfilled all expectations, and elevators are now being run in some of the large apartment houses without in the least affecting the lighting service. The company are pretty well convinced that it is in this direction that future extensions of the system at a distance from the generating stations will be carried out.

FUSES FOR BRANCH CIRCUITS.

BY S. H. SHARPSTEEN.

THERE is much appearing in the electrical papers in relation to electric wiring, but the writer thinks that there are some points of fundamental importance that have not been touched upon.

The matter of fuse lengths for circuits of about 100 volts entering buildings for incandescent work, has never been considered as it should have been by the fire underwriters. The underwriters' inspectors will enforce many matters of no importance and will allow a small house to be connected by service wires to a circuit from a 300 or 500 light transformer. If the lightning punctures the insulation of the transformer, or if the insulation gets broken down from other causes which are common and happen every day, the house wiring is, or may be, subjected to 1,000 volts or more pressure. A weak place in the insulation of the house wiring gives way, the current goes through to the ground, the fuse blows in the fuse block on the branch, since it cannot be above 6 ampere capacity, and comply with the rules, but the 1,000 volts pressure crosses after the 6 ampere fuse has gone; since the gap will not open a 1,000-volt circuit the branch block burns up and possibly the building is fired before a fuse goes somewhere to relieve the trouble.

Until recently it has been the practice to place a fuse in bracket or fixture just large enough to carry current for the lamps on bracket or fixture. In case of a combination bracket with one 16-candle-power 100-volt electric light, a fuse of 1 ampere capacity would be large enough. If the primary current of 1,000 volts should start through the wiring of this fixture to the ground, its fuse would be very apt to be the first one blown, but the fuse gap would not be sufficiently large to open the 1,000 volt circuit; hence the porcelain would crack and fall to pieces and the wire be set on fire.

If the transformer be 500 light the primary fuse may be all the way from 25 to 40 ampere or even a piece of No. 12 copper wire. It is not absolutely necessary for the transformer insulation to break down since, either by a bare wire drawn across a service wire and 1,000-volt main or by the service wire coming in contact with a 1,000-volt main, the house wiring may get a 1,000-volt current.

The average person will suppose that the main fuse at the entrance block will go on such an occasion, but for a building of 100 lamps the main fuse would have to be at least a 50-ampere, and a 50-ampere fuse would hold for a long time on many of the 1,000-volt circuits where they run for miles and are of pretty small wire.

Many persons engaged in the electrical business may have their doubts as to getting the proper combinations for such trouble but the writer had two cases come under his notice, both in the same house and both cases only a few months apart. The house was the home of J. M. Johnson, Binghamton, N. Y.

In the first case there was evidence to convince one that the mica insulating joint and the insulation of the wire in a bracket had broken down and the rubber-covered wires that came through the porcelain tubes in the plaster were burned up for one and one-half inches into each tube; the arc had burned the tubes away somewhat. The tubes came through lath and plaster and the ends running out into the canopy had been very hot. If the outlets had not been run through porcelain tubes one can imagine what the result would have been as the cross occurred in the night.

Mrs. Johnson complained of smelling rubber burning, but no search was made. There was a black place on the wall about 14 inches in diameter, the horse shoe cut-out was in many pieces and the insulation was almost all off the insulating joint. The writer was the first one to remove the burned canopy and he asked if all the lamps in the house did not refuse to burn the next day, and the answer was, "Yes," and they also said "that another house did not have any light until after the transformer was changed."

The second case occurred in the daytime and was quite amusing. For some reason there was a gas tap in the kitchen outside of a canopy of an electric bracket. The help about the house had been in the habit of hanging some kitchen implement on the gas tap and it seems that the implement while hanging on the gas tap got against the canopy of the electric fixture and the conditions were right to ground the primary circuit of 1,040 volts. The kitchen help on seeing the fire between the gas tap and the bracket ran out in the back yard.

The fuses controlling the various branches were in a closet on the second floor and when the cross occurred one set of fuses went off, but the arc held and roared so that some of the occupants of the house who were on the floor became frightened and ran into the yard to join the others. The transformer was burned out again and another was put in its place. The branch block that was in circuit with the trouble was broken all to pieces and if it had not been on plaster might have set the building on fire. In neither case did the main fuse blow.

The writer has a lamp and socket in which the filament was burned up in the lamp and the socket gear and case are badly burned. This was on a 104-volt circuit and was the cause of trouble either in the transformer or from service wire coming in contact with arc or power circuit.

Not long since the writer called at an electric railway power house and found some men trying to pound a brass bearing off from the armature shaft of an old VanDepoele motor that had been used to drive some iron working machinery. It seems that it had been running the night before when the power house was shut down and was not disconnected from the switchboard. The generator switches had all been thrown but this shop machine had been left connected with bus bar, and bus bar connected with trolley wire and mains.

Some time after midnight the watchman heard this motor running at a tremendous speed and since all the generating machinery in the power house was shut down he concluded that the shop motor had become bewitched, and would not go near it to throw the switch to disconnect it. The result was that it kept on running and it seems that it received its current from an arc wire that had got crossed with the trolley wire and having a good big voltage ran at a tremendous speed. For the want of proper lubrication it got a hot bearing and ceased to go even the next day when it was wanted to run the shop again.

Some electricians, purely theoretical, may wonder where the current from the opposite side of the 1,000-volt circuit is going to get into the ground; this is a good subject for an article of a number of columns. But suffice it to say that in practice if there is a good ground on one leg of a high pressure circuit, the circuit being made up of weather proof wire and being strung for miles in every conceivable direction oftentimes through the leaves on trees, the current will get through on the other side, although the amount might be small. Two amperes is all that is necessary to make serious trouble and the fact that only a few amperes being able to pass might make the trouble all the more serious as the arc would hold longer without some larger fuse blowing of a greater fuse gap. This leakage might occur much easier during a rainy season. It is amusing to hear some insurance inspectors tell how secure they know circuits to be against this kind of trouble.

There is no question that it is a common thing to get the primary current of an alternating system, into house wiring or wiring intended for a pressure of about 100 volts, and since such a thing is liable to happen at almost any time, does it not seem strange that the fire underwriters will allow branch blocks with small gaps to be used? The wires are crossed when they are put into the branch block and when the branch block is cracked to pieces the wires lie one across the other.

The fire underwriters will allow as a rule but a few lamps on one branch circuit distributing current to lamps; for safety from fire each one of these branch circuits should have a pair of fuses long enough to break a current coming from the highest voltage circuit in the city.

PLAIN TALK ON ELECTRIC LIGHT AT GRAND RAPIDS, MICH.

THE Grand Rapids Electric Light Company, through Mr. W. T. Powers, its president, and Mr. J. W. Spooner, its secretary, has issued the following pithy and pertinent appeal to the local public: We desire to offer a few suggestions in regard to a municipal lighting plant, and while we may be accused of being an interested party, we want the citizens of Grand Rapids to understand our position.

We have had several years' experience in lighting the city, and know that the city could not reap any benefit from running their own plant. And at this time, when over 2,500 descriptions of real estate are advertised for sale for taxes in every Wednesday's Herald, it seems a poor time to add anything to the taxes, which are already a burden.

There is a strong competition in the electric lighting business here, and on a long contract the city could obtain a proposition from three different plants, two of them operated by water power. There is also a fourth party that has a very reliable water power within reaching distance, which is ample to give all the power that the city would need for some years to come, and we understand this party would also bid on a long contract, and could afford to do the business at a much lower rate than the city could make lights for, with coal. The claims that have been made that we were anxious to get the city into a corner and charge $150 per light is a pure falsehood, and right here it might not be out of place to let the public know how we came to charge that price for lighting. When the council determined to light the city with towers they passed a resolution specifying a certain tower, upon which we had to bid to get the contract. These 40 towers cost us $38,000, which was $14,000 more than we could have purchased just as good a tower for.

Our contract provided that at the end of three years the city could purchase the towers from us for $20,000. Consequently we were obliged to add that portion of the towers to our bid.

We are now getting from the city $107 per light for 380 lights of 2,000 candle power each, and for all lights in excess of 380 we get $97 per light, and we have made the city a proposition on a contract for $97 per light for all they need.

We have also offered to duplicate the prices obtained by the city of Detroit in their new municipal plant.

We do not pretend to say that the city could not do even better than this. The only way to find out would be to advertise for bids.

MECHANICAL

THE WELLINGTON SERIES ENGINE.—A NEW SYSTEM OF DEVELOPING POWER FROM HEAT.

THE new type of engine described below is the invention of the late A. M. Wellington, who devoted the last years of his life to its development, but who, unfortunately, was not permitted to carry out to their complete fruition the remarkable ideas embodied in his invention.

At the outset, it may be said that the Wellington series engine is an apparatus designed to convert heat into power with a greater efficiency than is obtained in the best existing forms of steam engine. For example, the very best existing steam engines convert into mechanical work some 10 per cent. to 12 per cent. of the total heat generated by the fuel burned in the boiler furnace. A thermodynamic analysis of the Wellington engine shows that it should effect this conversion with much greater efficiency; and if made commercially successful should convert into power from 25 per cent to 40 per cent. of the total amount of heat generated by the fuel which it consumes.

In general it may be described as an arrangement of several ordinary steam engines in a series, with their respective boilers and condensers arranged in such a manner that the wastes of one engine are utilized in the next. In other words, the heat discharged from one boiler is utilized in the next one of the series, and the heat accumulated by passing the cooling fluid through the several condensers in series is also utilized to economize the fuel consumption.

The general principle of operation of the engine is illustrated in the diagram plan, Fig. 1. Here A, B, C, D, E, are a row of ordinary steam engines, each supplied with steam from a boiler on one side of it and exhausting into a surface-condenser on the other side. The liquid which accumulates in the surface-condenser is pumped back into the boiler by a pump attached to the engine.

The boiler, engine and condenser, marked B, are exact duplicates of those marked A, and the same is true of the set marked C, the set marked D, and the set marked E. Evidently now if a furnace were attached to each boiler and a suitable supply of cooling water were piped to each condenser, we would have five complete working steam power plants, each independent of the other.

But now suppose that instead of burning fuel under each boiler we place a single furnace at the right hand end of the row, and pass the hot gases from it first through the tubes of boiler A, then through the tubes of boiler B, then through boilers C, D and E. Also suppose that we connect the several condensers so that the cooling water flows first through condenser E, then through D, and so on till it finally leaves condenser A. It is evident that each separate set, consisting of boiler, engine and condenser, will still be operative, and that we may expect a greater total output of power from a given consumption of fuel and condensing water than before, for by the successive passes the heat will be pretty thoroughly extracted from the furnace gases by the boilers, and likewise the condensing water will be heated up to about the point at which it is no longer efficient by the time it leaves the last condenser.

Of course, with the arrangement above described boilers A and B would make a surplus of steam, while boilers D and E would make very little. On the other hand, the condenser E would be very efficient; condenser D would be somewhat less efficient, and so on until condenser A would probably have difficulty in maintaining a proper vacuum.

If the above simple discussion is plain to the reader, he will have no difficulty in understanding the Wellington engine. In this engine, as illustrated by diagram in Fig. 2, we have a "circulating fluid" which takes the place of the hot gases from the furnaces and the cold condensing water in the mechanism just described. This circulating fluid may be either a liquid or a gas, but for the present purposes, let us consider it a liquid, which fills all of the piping in the entire circuit from the heater at the left hand end, through the tubes of the several boilers from A to E, then through the tubes of the cooler, then through the tubes of the several condensers from E to A, and finally into the heater again. The liquid is caused to circulate by any suitable form of pump. It will be seen at once that by the use of a continuous circulating fluid, all the heat which is accumulated as the fluid passes through the several condensers is not lost as in the example first cited, but is directly utilized and lessens by just so much the fuel consumption in the heater.

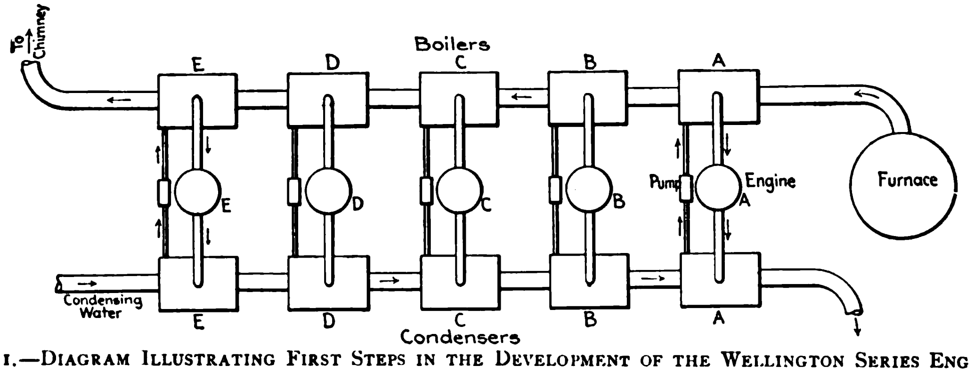


FIG. I.—DIAGRAM ILLUSTRATING FIRST STEPS IN THE DEVELOPMENT OF THE WELLINGTON SERIES ENGINE.

Now, finally, to avoid the inequality of operation noted in the first example, and to make every engine, boiler, and condenser perform the same amount of work with the same efficiency as every other one in the series, a uniform "heat interval" is adopted for each boiler and for each condenser. By the term "heat interval" is meant the number of degrees difference of temperature between the water in any boiler or condenser and the circulating fluid which is imparting heat to the water in the boiler, or absorbing heat from it in the condenser. These various temperatures are marked upon the diagram, Fig. 2.

Suppose also that the pressure of the steam in each boiler is that due to a temperature 10 degs. less than that of the circulating fluid leaving that boiler, and that a similar difference of temperature exists in each condenser between the temperature of its contents and the temperature of the circulating fluid laving it. Then the temperature in boiler A will be 434 degs., and in condenser A, 278 degs. Then the absolute pressure of steam in boiler A will be 355 pounds and there will be a back pressure in condenser A of 48 pounds. In a similar way we find that boiler B will work at a pressure of 192 pounds and a back pressure of 21 pounds will exist in condenser B. In boiler E a pressure of 14 pounds absolute will exist and the condenser E will have a vacuum of 28 ins.

It will be evident that under these conditions with water and its vapor used as the working substance in each engine, as we have assumed, the engines toward the right will do a much larger amount of work than those toward the left. But now suppose that instead of using water as the working substance in each engine, we use it for one or two engines only, say for engines A and B, and for the engines C, D and E we adopt a working substance which will evaporate at a lower temperature, so as to give approximately the same amount of work with the same drop in temperature that occurs in boilers A and B. The progress in refrigerating machinery has given us quite a list of substances which are now extensively used under conditions similar to those which would obtain here. We may mention, for example, ammonia and carbon-dioxide.

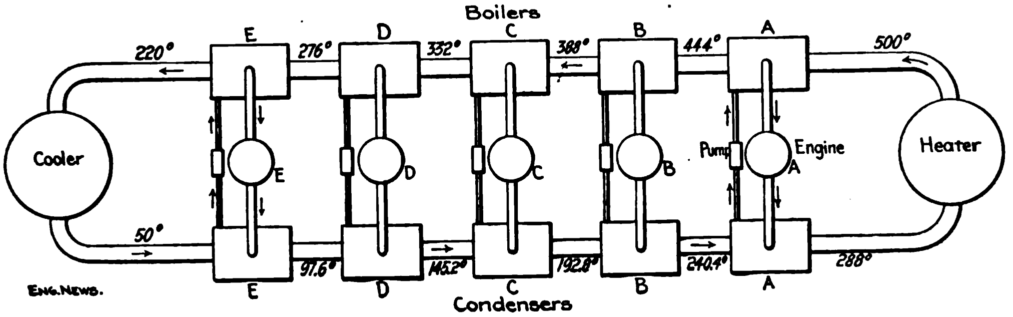

FIG. 2.—DIAGRAM ILLUSTRATING OPERATION OF WELLINGTON SERIES ENGINE.

On the other hand, it is not essential that different working substances be used in the different engines: on the contrary, the advantages of simplicity due to the use of steam alone as the working substance may cause that to be adopted except in cases where so large an amount of power is to be generated as to make the greater economy due to the use of different working substances an important object.

It will be seen, for example, that with a series of five engines, as shown in Fig. 1, we could use water as the working substance in all, and by varying the amounts of heating surface in the different boilers and condensers, we could secure the same output of work from each one of the five engines. More in detail, we would give boiler A a small heating surface, boiler B a greater amount, and so on till boiler E would have the most of all. On the other side of the circuit, condenser E would have the least surface and condenser A the most.

Turning now to the boilers and condensers to be used with this new form of engine, it is apparent at once that an entirely different structure from the ordinary boiler is required, and upon the successful design of such a structure the practical success of the invention as a whole is doubtless dependent. If a series engine were to be built with boilers of the ordinary externally fired type, their bulk and the loss of heat by radiation would alone be sufficient to make the apparatus impracticable and inefficient as a heat engine.

In the boilers of the Wellington series engine the heating surface is no longer acted upon by a hot gas, but by a hot liquid, which can convey heat to the surface many times as rapidly as hot gases from a fire. Thus a square foot of heating surface in the Wellington boilers will transmit many times as much heat as in boilers of the ordinary type. Besides, in the Wellington boilers there is nothing to cause any deposit on the heating surface, either of scale on the one side or soot on the other.

It will be apparent from the above that in point of bulk the boiler belonging to each separate engine in a Wellington series set is not to be likened to an ordinary boiler at all. It would be much more nearly like a surface condenser, though much smaller still, and every engineer knows that a surface condenser for even an engine of large power is by no means a very bulky apparatus.

Mr. Wellington in his study of this feature of his invention became convinced that it was possible to construct boilers for his engine which should have an enormous power in a small space. Practically the entire experimental work which was done upon the invention was in this field, and that it was in some degree successful will be evident from the fact that a 2-horse-power steam engine was actually operated at full load by steam from a boiler with a bulk of less than 1-10 of a cubic foot. This boiler was only 9 inches long and 5 inches in diameter, giving a volume of only one-tenth of a cubic foot. Yet in an actual test it developed 1½ horse power when evaporating a petroleum distillate with a boiling point of 80 degs. Fahr., and heated by a stream of water at 212 degs. Fahr.

The second boiler of this type is shown in Fig. 3, the tubes and tube plates being removed from the boiler shell.

The fact that a boiler of this type has actually been built and worked which generated 40 horse power with a weight and bulk only one two-hundredth as great as the ordinary stationary boiler of that power is certainly one calculated to command the attention of engineers.

Very soon after this larger boiler was built, however, Mr. Wellington hit upon an entirely new plan of boiler construction by which he hoped to go even farther in the direction above noted in the reduction of weight and bulk for a given power, and at the same time to make a boiler which would be constructed at a far less cost than the tubular boiler. Space forbids us to do little more than describe the general principles of this boiler.

It consisted of a series of copper plates about 15 inches in diameter, which are covered with peculiar corrugations or channels. These were joined together in pairs, the edges of each pair being brazed so that the two plates facing each other formed a closed chamber. A number of these pairs are placed in a tubular case and are so connected to pipes at the top and bottom that fluid can circulate through them. Pipes are also connected to the case in which these sections are placed, so that the circulating fluid which heats the working substance will pass through the narrow channels which are left between each pair of plates. In this manner an enormous amount of heating surface is obtained in a very small space. In fact, this type of boiler is far superior even to the tubular boiler shown in Fig. 3 in this respect.

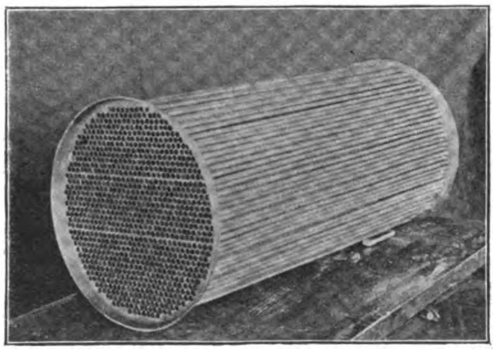

FIG. 3.—MULTITUBULAR BOILER FOR WELLINGTON SERIES ENGINE (TUBES REMOVED FROM SHELL).

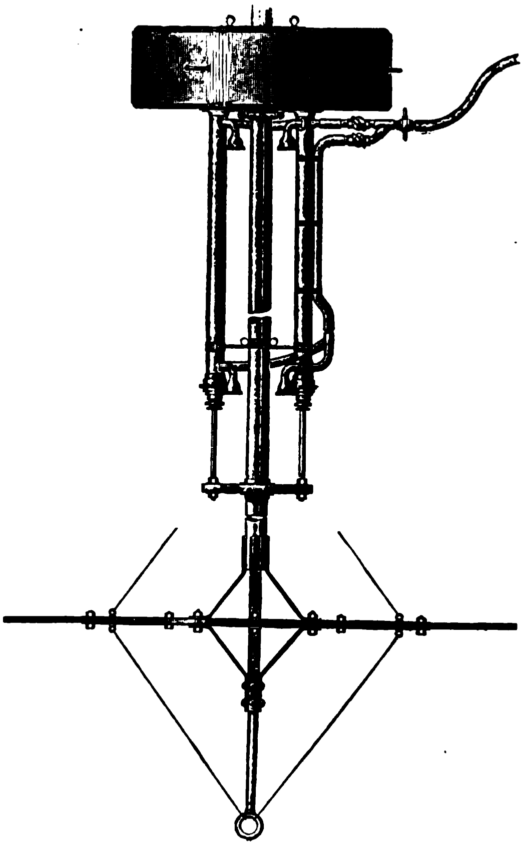
So promising did this invention appear as a means of solving the problem of the transfer of heat in small space with a small temperature interval, that a great part of the work done in the development of Mr. Wellington's invention was devoted to the design and perfection of this plate boiler. A boiler was actually built made up of 26 sections, with plates 16 inches in diameter and containing 208 square feet of heating surface and a great amount of experimental data was accumulated respecting the best methods of manufacture of boilers of this type.

Of course, in the development of this invention a great variety of details were worked over and developed; but space does not permit their description here. Our readers who desire to study the invention in more detail are advised to secure copies of U. S. patents Nos. 549,981, 549,982 and 549,983, issued Nov. 19, 1895, which cover the invention and various modifications in detail. These patent specifications form really an elaborate treatise on the series engine, including an extended discussion of its theory.

FLETCHER'S DEVICE FOR THE UTILIZATION OF WAVE POWER.

ENGINEERS have long endeavored to devise a practical plan whereby the power of the action of waves and tides may be conserved, and the energy either utilized immediately, or accumulated and stored for future usage. Granted that an efficient apparatus can be devised whereby even a tithe of the energy can be made available, it is obvious that the purposes to which it can be applied are almost without limit.

We are indebted to Industries and Iron for a description of an ingenious apparatus, invented by B. Morley Fletcher, A. M. Inst. C. E., of Westminster, which would appear to utilize ample power at a practically nominal cost. Briefly, the essence of Mr. Fletcher's invention is the provision of a point of resistance which is fixed in relation to the up and down motion of the waves. This is attained by means of a submerged horizontal plane or disc, which is anchored to the sea bottom by powerful and efficient moorings, chains, bridles, etc., due provision being made for the rise and fall of tides. This plate is placed at such a depth below the surface of the water that it is entirely unaffected by the action of the waves. The motor itself consists of two parts; first, a cylindrical tube or hydrometer at right angles to and firmly secured to the upper surface of the plate alluded to, and rising a few feet above the surface of the water. And, second, a cylindrical or other shaped buoy, which floats on the waves around the tube, and which has attached to it a pump barrel, which in its turn works around the tube immediately below the buoy. The motion of the barrel is therefore synchronous with the movement of the waves, in a vertical, horizontal, or angular position. In other words, the pump barrel moves up and down in the direction of the waves, and the fixed tube provides a piston-rod; that is, instead of the piston-rod moving in the barrel, the barrel moves up and down the piston-rod. The water pumped can, of course, be conducted by suitable means to the shore, and there used or stored for hydraulic purposes, or it can be conducted on board lightships, piers, harbors, etc., and employed in generating mechanical force in connection, for instance, with the generation of electricity, for lighting, signaling, and other purposes. The condition of the sea and weather in no way interferes with the effective working of the apparatus.



Fletcher's Wave Power Motor.

A demonstration with an experimental plant in Dover Harbor, has given results which are regarded as fully warranting the further expenditure necessary for the construction and laying down of a much larger and more powerful plant. The Dover plant, illustrated in Fig. 1, when in full work, is capable of developing about 3.7 i. h. p. with a maximum stroke of 4 feet, the diameter of the floating buoy being 4 feet, and the size of the pump barrel only being limited by the size of the buoy. A larger plant is now being constructed. This apparatus, which has an inner tube 12 in. in diameter, is designed to develop 300 i. h. p. when working at full stroke. When it is working at one-half stroke the same pressure of 150 lbs. per square inch is obtained.

Not the least ingenious portion of the design of the apparatus is the controlling gear, which is to be employed when the sea is rough. As a further precaution, the buoy is so designed and placed as to be always from one-half to two-thirds immersed, so that heavy waves will pass completely over it without in any degree interfering with the efficient action of the pump, or causing injury to other portions of the plant. Where necessary, the plant can be readily duplicated or triplicated, its low cost being an additional inducement.

One of the first uses which suggests itself for a practical invention of this kind is in contributing to safer navigation around sea coasts, in channels, the entrance to dangerous estuaries, and the like, during foggy weather. By fitting to the plant apparatus for actuating and sounding foghorns or sirens, the restless action of the sea would at once enable the navigator to ascertain his true position. A system of colored electric lights, flash lights, etc., might also be fitted on the buoy in a similar manner, and worked continuously, or at will, both by night and day, regardless of the condition of the prevailing weather, thus appreciably reducing the loss of life and property through collisions and wrecks.

TELEPHONY AND TELEGRAPHY

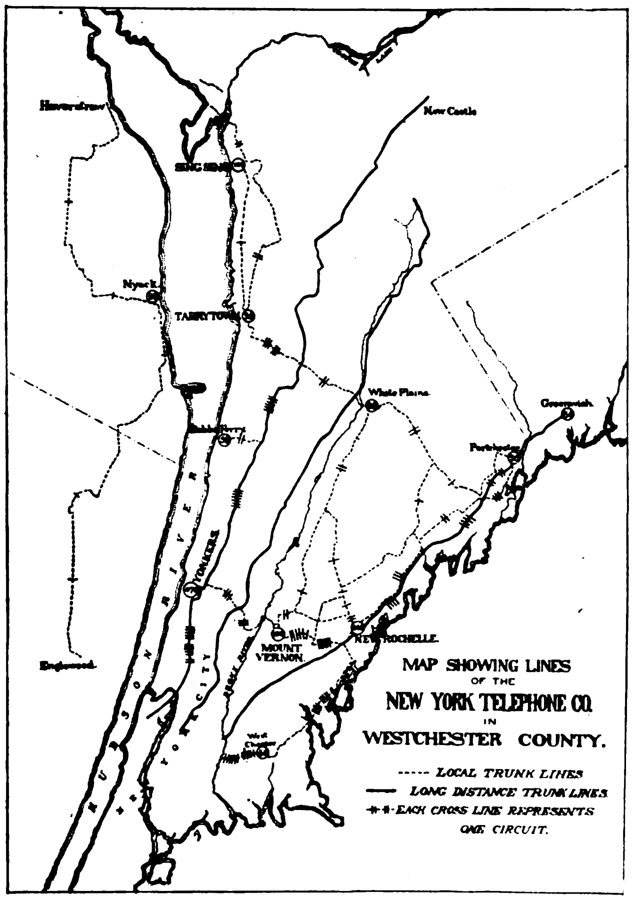
RECONSTRUCTION OF THE TELEPHONE LINES IN WESTCHESTER COUNTY, N. Y.

THE overflow of a large part of the population of New York City into the adjacent county of Westchester, rendered the annexation of a slice of that county necessary long ago; but the process of expansion still goes on, and literally the whole of what remains as Westchester is New York, all its interests being so closely and indissolubly connected with those of the metropolis. The region by its extent, beauty and rolling character, is curiously like that which stretches away southeast from London down through Surrey and Kent, and it bids fair at no distant date to afford yet another resemblance in its dense population. To meet the needs of this suburban district, the steam roads have multiplied their service, the trolley lines are reticulating it in every direction, and now the telephone system has come in for an enormous development and thorough reconstruction. For some time past the New York Telephone Company, having gathered all the people in Westchester under its wing—not overlooking a bit of affiliated territory at Greenwich, Conn., and a big strip across the Hudson in Rockland County, encircling Nyack—has been steadily improving its facilities with notable results. But just as a new hall carpet or a new piece of furniture in the parlor requires that the whole house shall be keyed up in its other appointments, so the work done has made the company resolve to equip afresh throughout and the result is that a sum in excess of $250,000 is now being spent by it in bringing the entire telephone system in that region up to its ideas of what is fit and proper.

It will surprise many of our urban readers to learn that the New York Telephone Company has in Westchester County no fewer than 1,500 subscribers, and that of these no less a proportion than 75 per cent. are on metallic circuits. The exchange groups at the time this data was collected (March 27) ran as follows: Dobbs Ferry, 53 subscribers; Greenwich, 84; Mount Vernon, 122; New Rochelle, 248; Nyack, 99; Port Chester, 95; Sing Sing, 109; Tarrytown, 95; Westchester, 46; White Plains, 88, and Yonkers, 475, making a total of 1,524. Some notion of the expense of maintaining and reconstructing telephone systems may be formed from this single case, which shows that at least two years' total receipts will be required to cover the new outlay, the bulk of the old lines, and a great deal of the old apparatus being at the same time converted into mere junk.

To descend to details, it may be stated that all the trunk lines connecting the offices named are to be reconstructed. This involves rebuilding all the pole lines between central offices, substituting larger poles, and providing copper wire everywhere. Every inch of iron trunk wire in the territory is now being taken down. In several places, the exchange lines not now in good condition, through wear and tear, are being overhauled and in many cases aerial cables will be substituted, where the number of lines permits. The general appearance of the streets will be greatly improved.

When we come to the exchanges, a great amount of work is visible. At Yonkers, a great deal of new equipment is necessary. The switchboard is being enlarged, more underground cables are being placed, and all the overhead wires will be thoroughly renovated. At New Rochelle, the company will replace the present office with an entirely new one, and put the principal lines underground. Unless suitable quarters can be obtained, the company will build its own exchange, after the plan of the admirable one-story telephone substation buildings in Buffalo and Rochester. At Greenwich, Conn., the office was completely overhauled when it was transferred from the Southern New England Telephone Company, but it is proposed to add to the facilities. Territory along the Long Island Sound will be opened up, and arrangements are now being made for the benefit of beautiful Bellhaven, which may be regarded as the Newport of Greenwich. Through all this region and elsewhere in the territory new offices are to be opened, and the pay station service is to be greatly extended.



At Port Chester, there will be an entirely new office equipment, and at Mt. Vernon, White Plains, Sing Sing, Tarrytown and Nyack, new or added equipment will expedite the service. In some of these places, the growth is relatively slow; in others it bids fair to proceed at an accelerating pace, and it is no mean difficulty to decide just what the provision for the future should be. The map we present affords an interesting basis for speculation or calculation in this respect.

The organization of this large territory is a matter of some interest. In point of fact, the center of the district is Yonkers, where the divisional superintendent is in charge of all ordinary operation, repairs, addition of new subscribers, and current maintenance. To this superintendent all the managers at the different central offices report. When we come to heavy construction and large reconstruction, all this is found to be done in accordance with elaborate plans prepared by the New York Telephone Company's city engineering department, and carried out under its direct supervision.

This article would not be complete without some reference to the charges obtaining in the district under discussion. We are therefore glad to append schedules which will show what the conditions are in this respect:

Flat rates for exchange service.—Metallic circuit.—Wall set within one mile of central office.

YONKERS.

	Annual.	Season of six months or less. Payable in advance.
Business—Direct line	$90.00	$67.00
Two-station line	75.00	56.00
Three-station line	60.00	45.00
Five-station line	50.00	37.00
Residence—Direct line	75.00	56.00
Two-station line	60.00	45.00
Three-line station	50.00	37.00
Five-station line	40.00	30.00

OTHER PLACES.

	Annual.	Season of six months or less. Payable in advance.
Business—Direct line	80.00	60.00
Two-station line	70.00	52.00
Three-line station	60.00	45.00
Five-line station	45.00	34.00
Residence—Direct line	70.00	52.00
Two-line station	60.00	45.00
Three-station line	45.00	34.00
Five-station line	36.00	27.00

Cabinet set $10 per annum, or season, extra. Extra mileage, $40 per mile, per annum, actual line measurement; $10 for each one-quarter mile.

Measured exchange service.—Metallic circuit—wall set. Within one mile of central office.—Message rates.—Sent local messages. (With the right to receive any number of messages.)

YONKERS.

	Direct Line.		Two-Station Line.		Three-Station Line.	
Messages per annum.	Rate per annum.	Excess messages.	Rate per annum.	Excess messages.	Rate per annum.	Excess messages.
500	$60.00	10 cts.	$50.00	10 cts.	$40.00	10 cts
600	70.00	10 "	60.00	10 "	50.00	10 "
700	78.00	9 "	68.00	10 "	58.00	10 "
800	86.00	8 "	76.00	9 "	66.00	9 "
900	93.00	8 "	83.00	8 "	73.00	8 "
1,000	100.00	8 "	90.00	8 "	80.00	8 "

OTHER PLACES.

	Direct Line.		Two-Station Line.		Three-Station Line.	
Messages per annum.	Rate per annum.	Excess messages.	Rate per annum.	Excess messages.	Rate per annum.	Excess messages.
500	$50.00	10 cts.	$40.00	10 cts.	$30.00	10 cts

1,400	98.00	6 "	88.00	6 "		
1,500	102.00	6 "	92.00	6 "		

Extra Mileage—$40 per mile per annum, actual line measurement; $10 for each one-quarter mile.

SUBMARINE CABLES AND SUBMARINE EARTHQUAKES.

A break in the cable laid between the Senegal coast of Africa and Pernambuco in Brazil five years ago has led to an extraordinary discovery, related recently by Mr. Benest to the English Institution of Electrical Engineers. The cable was as fine a one as modern methods could devise, yet after three months it broke about 150 miles from the African coast; it was repaired and broke again. It was then found that at the place where the break occurred there was a great deal of vegetable growth resembling river weed; that the color of the sea was a dirty brownish green, indicating the presence of fresh water, and birds' feathers, pieces of orange peel, scraps of carpet, and bits of driftwood were drawn from the bottom of the ocean. The phenomenon was purely local, as the nearest river was seventy-five miles away and discharged its waters in a different direction. It was surmised that it meant the sudden breaking through of a submarine river, and the cable was moved to a distance; after two years it broke again and was moved once more, and engineers are waiting to see what will happen. Submarine rivers are known to exist in other parts of the ocean, off the mouth of the Congo and in the Gulf of Carpentaria, for instance. This explanation, however, does not account for the carpet and the orange peel.

THE B. & O. TELEGRAPH SYSTEM.

Superintendent Charles Selden, of the B. & O. Telegraph, said the other day that the average number of messages handled every day on the B. & O. system was 53,000, exclusive of train orders. The B. & O. have 22,252 miles of telegraph wire, of which they use 7,240 for company's business and the balance is leased to the Western Union. There are 384 telegraph offices on the line, of which 234 are reporting Western Union offices. Mr. Selden employs in his department 750 men, exclusive of linemen. He also has charge of the Block Signal offices which east of the Ohio River average one to every six miles. The service of the company's plant is considerably augmented by the use of several multiplex systems.

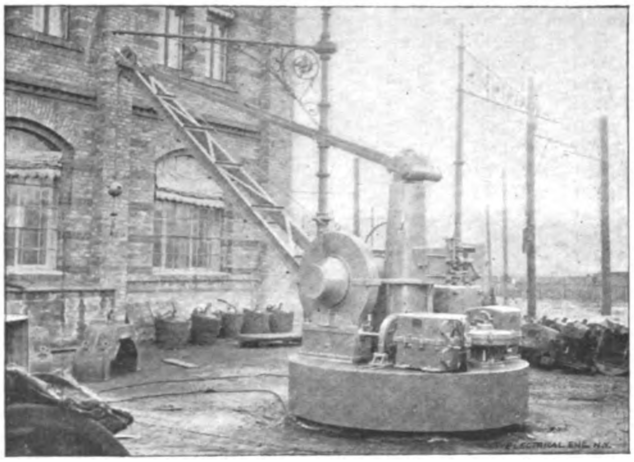
HIS OWN TELEGRAPH MESSENGER.

A drummer who travels in Maine is not greatly impressed with the rapidity of the telegraph service in that State. Recently he was in the upper part of a county and wanted to reach another town that night. He telegraphed the hotel keeper in the latter place early in the day to send a team to the station for him. When he reached the station at night no team was there, so he started to walk to the village, which was quite a little distance off. No sooner had he started than the station agent said to him: "Are you going to the village?" "Yes." "Then I wish you would take a dispatch up to the hotel." It was the dispatch ordering the team.—Boston Record.

POWER TRANSMISSION

NEW ELECTRIC SHIP CRANE ON GERMAN DOCKS.

ONE of the large German transatlantic steamship companies has recently been investigating the question of electric cranes for use on shipboard and our illustration shows a type selected for the work. It is shown standing in the yards of the factory of the Union Electricitäts Gesellschaft, Berlin. The construction of this crane is of the most substantial character necessitated by the hard usage it is likely to receive on shipboard. It is so designed that the load can be transported from hold to dock or to another boat without interfering with the bulwarks or moving the load first to the deck. This crane is both lifting and rotary and the entire construction is so simple that one man can operate it without difficulty.



Ship Hoist Built by Union Electricitæts Gesellschaft, Berlin.

The design of the gearing is such that the moment the load is raised to the requisite height, an automatic brake is applied. The raising motor is connected to a cast steel gear running in oil and driven by a pinion; a second motor serves to rotate the crane. The crane is started, the speed regulated and the motors revolved by special controllers completely enclosed. The resistances are set underneath the platform in cast iron compartments readily accessible. The two controllers as well as the two motors are operated by means of one lever and the movements of this coincide with the movements of the crane itself. Raising the lever raises the load; turning it to the right turns the crane to the right, and if the lever is raised and turned at the same time, the load is raised and turned coincidently. To guard against the action of sea water, bad weather, etc., the electrical mechanism is entirely enclosed and is water-tight. A special brake operated by the foot is used to check the movement of the motors in case of necessity.

The capacity of the crane is about 5,200 pounds and the speed of lift under full load 68 feet per minute; at no load 108 feet per minute and with shunted fields 148 feet per minute. The raising motor has a capacity of 25 horse power and the rotating motor 7.5 horse power. The length of the boom is 18 feet and the speed of rotation at the end of the crane 13 feet per second.

In a recent competition for the construction of large shipping cranes, the Union Electricitäts Gesellschaft's apparatus was selected on account of the simplicity of construction and operation of the machine. It will be seen that the electrical equipment is practically American and was selected in competition against the best European manufacturers.

In view of the satisfaction given by the crane above described the North German Lloyd has decided to equip its new ship, the Bremen, entirely with electric hoisting apparatus. This vessel will receive 16 cranes similar to that shown in our illustration, and four direct connected, six pole, 75 kilowatt, 210 revolutions, 104-volt generators. Two of these will be devoted to the operation of the cranes, a third will serve to light the ship, the fourth being held in reserve.

ELECTRIC POWER FROM A NEW MEXICO COKING PLANT.

MESSRS. H. WHIGHAM and S. A. Schomburg, of the Raton Coal and Coke Company, are now installing at Blossburg, N. M., three miles from Raton, a new coking plant, embracing about seventy-five three-foot ovens in double banks. In the center will be erected a large battery of boilers, to which the waste gases of the coal will be conducted through central flues. The power thus generated will be converted into electricity to furnish power for the whole plant inside and outside of the mine. About one and one-half miles from the coke ovens will be situated the Robinson washing and crushing plant, which is now in process of construction. It will have a capacity of 800 tons each ten hours. The waste coal from the washing plant will be taken down a larry line by a small steam locomotive in seven-ton larry cars, each car carrying a charge for an oven and delivering it directly over and into the oven. All of the machinery, from tipple to mine opening, will be driven by electric motors and in the main entry a trolley line is being built on which an electric locomotive of 150 horse power will bring the pit cars to the tipple. The latest improved mining machinery run by electricity will drive all of the entry work.

A CURIOUS POWER SCHEME.

A BILL recently introduced in the New York State Legislature is exciting considerable comment as to what the promoters of the project propose doing should they secure the rights asked for. On its face the bill incorporates the "Columbia Electric Power Company," the promoters of which are three men named Wild, residents of Columbia County. Further, the bill authorizes the formation of a company with a capital stock of $10,000,000 for the purpose, ostensibly, of damming Kinderhook Creek, a small tributary of the Hudson River, and thereby generating electric power. One remarkable fact is that the company does not seek to be incorporated under the general incorporation act, and this is in part explained by the several peculiar features of the bill, one of which is that the bill gives permission to extend the lines of the company to all parts of the State, subject only to local ordinances in cities and towns, and another which allows the taking of additional power wherever and in whatever manner it may be necessary for the business of the company. The company would also have the right to take lands by condemnation proceedings. It is pointed out that under these broad provisions the Columbia Electric Power Company could, for example, erect a plant at Niagara Falls to compete with the companies now located there, thus securing a franchise to do business at a point where the granting of further power rights is strongly opposed by the commissioners of the State reservation. Under such a franchise the company could also dam the Hudson, but the bill is being closely watched, and if it becomes law its provisions will likely undergo a great change.

LETTERS TO THE EDITOR

FIRE TUBE STEAM BOILERS.

UPON reading the article by M. C. D. in your magazine, we are prompted to enter a plea for the return tubular boiler, which he seems to think little short of a dynamite bomb.

There are to-day thousands of these boilers in use to every water tube boiler, and there is no difficulty to get them passed by the Hartford Boiler Insurance Company, who are certainly the recognized authority on steam boilers. Can the same be said of all water tube boilers?

For efficiency the return tubular will give, if properly constructed, as good results, if not better than the other class, and requires far less attention.

It is true that very little property damage is done by the bursting of a water tube, and seldom direct loss of life, but can we overlook the hundreds of cases where employés have been scalded or otherwise injured, and thus bring a loss to the company through lawsuits?

The tubes of a return tubular boiler are never subjected to the direct heat of the fire as are water tubes, and consequently are not subjected to the same strains. To this may be credited the comparatively few explosions of return tubular boilers as compared to the total number in use.

To many engineers the article would seem to prove the superiority of the water tube, which is distinctly untrue. We do not wish to run down the water tube boiler, but think the author shows great injustice to the ability of makers and users of other boilers. The explanation of the Elmira explosion may be correct, but could also be charged to other causes which would have produced the same results on a water tube boiler. After all is considered, the cause of nearly all explosions is directly due to carelessness on the part of the maker or user of a boiler, no matter of what class.

Would M. C. D. kindly let us know what make of water tube boiler he is interested in? BINGHAM HOOD,
Egg Harbor Elec. Lt., Ht. & Pr. Co.
Egg Harbor City, N. J.

ARC LIGHT CARBONS AND THE NEW TARIFF.

THE appeal of a "Central Station Man" to the consumers of arc light carbons to take up the question of the proposed rate of duty on this article, is encouraging. There is no doubt of the consumer's being not only the party to suffer from the proposed duty, but he is also the only party whose protest will have any weight at Washington, for, as correctly stated in the "Central Station Man's" letter, neither the manufacturer nor the importer of foreign carbons feels disposed to do anything in the matter, believing they will have no chance as "interested parties." The consumers of imported carbons should, however, not hesitate to unite in order to oppose the measure, as the home industry will certainly not benefit through the same. Or, do the home manufacturers—who, I am told, are the instigators of the proposed higher rate—intend to derive any benefit? They could only do so either by raising their prices—in which case the consumer would again have to pay the "piper"—or by an attempt to compel the consumers of arc-light carbons to go back to the domestic product, which so far has stood in the way of efficient arc lighting.

It is a well understood fact that the present prices of the domestic carbons are due to competition caused by over-production, which, as far as the home manufacturers are concerned, becomes more serious as the public demand for efficient arc lighting increases.

Whether the domestic manufacturers have a right to appeal to the high protectionists with a view to stop progress in arc lighting, remains for the electrical fraternity to decide.

I agree with "A Central Station Man" that American manufacturers are sufficiently protected under the present rate of 30 per cent., and it is my opinion that the preposterous rate of 50 per cent. proposed by the new Dingley tariff bill will greatly injure the electrical industry which depends upon the better article that can not be made here.

"ANOTHER CENTRAL STATION MAN."
New York, April 16, 1897.

LITERATURE

A NEW BOOK ON SUBMARINE CABLES.

A WORK entitled "A Treatise on Submarine Telegraph Cables: Their History, Construction and Working," has been prepared by Mr. Charles Bright, C. E., F. R. S. E., and will be published by Messrs. Crosby, Lockwood & Son, 7 Stationers' Hall Court, London, provided that a sufficient measure of support can be obtained beforehand. The size of the proposed book is super royal 8vo., and it will contain about 600 pages, fully illustrated with drawings and diagrams specially prepared for it. The price to subscribers will be two guineas ($10.30), but after publication the price to non-subscribers will be three guineas.

Mr. Bright has been continuously occupied in submarine cable work for over fifteen years, so that he is amply qualified from extended experience to deal with the subject from the practical point, while the papers of his father, the late Sir Charles Bright, have provided him with unequalled material for the historical section.

Mr. Bright's work contains a complete history of submarine telegraphy, treating the subject from the financial and political as well as from the technical side; it deals with the science and practice of cable laying and working in all their engineering and electrical details, including description of the latest improvements in high speed machine transmission. The subject of insulation is dealt with exhaustively and the methods of manufacture in producing gutta percha and India rubber covered core are completely described. A valuable feature of the book, too, is the section devoted to patents in which all master patents are described fully and categorically. The book is one, in short, that an electrical library will scarcely be complete without, while it will specially appeal to the specialist in telegraphy, telephony and insulated wires. Orders for copies may be sent to this journal, or directly to the publishers at the address given above.

THE LIVING AGE.

The publishers of the "Living Age" have purchased the serial rights to the publication of "In Kedar's Tents," by Henry Seton Merriman, author of "The Sowers." "In Kedar's Tents" is an attractive story of adventure in Spain during the Carlist war. It is said to be full of incident, and to contain some clever sketches of character. The first chapters of this work appear in the "Living Age" of April 3, and continue through fifteen numbers.

The early April issues will contain some other papers of striking and timely interest. Among them, Mr. Gladstone's pamphlet on the Eastern question, which has so aroused the attention of the English people; Max Muller's Literary Recollections; Francis de Pressense on the Cretan Question; Leslie Stephen on Gibbon's Autobiography; and a reply by Sir Frederick Pollock to the article on the Hidden Dangers of Cycling which appeared in a March number of the magazine.

ANGEWANDTE ELECTROCHEMIE (Applied Electro Chemistry). In three volumes. Vol. 1., Primary and Secondary Batteries. By Dr. F. Peters, Vienna, A. Hartleben. 338 pp., 5 x 7 inches. Paper. Price, $1.60.

This is a new volume of the well-known popular series of the Electrotechnische Bibliothek. It gives descriptions of the more important primary and secondary batteries, proposed or used up to June, 1896. The work is made specially valuable by copious references to original sources of information.

Vol. XXIII. NEW YORK, APRIL 21, 1897. No. 468.

Notice of Removal.

THE ELECTRICAL ENGINEER.

is now occupying its handsome and commodious new suite of offices, entire south wing, eleventh floor, of the Beard Building, 120 Liberty street, New York City. It is not only thus most advantageously situated at the heart of the machinery and electrical district, but enjoys an increase of several hundred feet floor space. The offices are convenient to all railroads and ferries, and an invitation to visit them is cordially extended to all friends and patrons of the journal.

SMALL MARGINS OF PROFIT.

MARGINS of profit are generally small in these days, and depend to a great extent on economies. The recent meeting of street railway accountants has its value in helping to bring out the necessity of standardizing accounts, for only in that way can the operating of one road be compared with that of another or a group of others. We believe it possible to effect economies in almost every department of railway or lighting plants as they exist to-day, without lowering the salaries of competent men or lessening the efficiency of the system. But the managers and engineers must get together to find out how to do it, and this is the main raison d'etre of the great national associations of the local companies. The statement is quoted in regard to steam railroads, by Mr. J. H. Maddy, press agent of the B. & O., that the difference of one mill per ton per mile on freight carried by all railroads in the United States makes a difference of $80,000,000 in revenue. In a recent article in Scribner's Magazine, Mr. P. G. Hubert, Jr., mentioned a number of very curious and suggestive facts bearing upon the nature of the margin of profit in various industries. A girl who uses the left hand in adjusting a certain movement of the spindle instead of the right, does it about a fifth of a second faster than the girl who uses the right hand. When this apparently insignificant period of time is multiplied by millions it will be seen that the mill in which the faster method is enforced will forge ahead of the one in which it is not. In a flour mill in Indiana, the year's profit once came from using ten hoops on its barrels instead of twelve, as in former years. A large match manufacturer saved $8,000 in one year by the use of a machine which pasted the labels on the match boxes. Before that the work was done by girls—who put on 20,000 labels a day, and got 80 cents for doing it, or at the rate of 250 for one cent. If any of our readers can match these figures with corresponding items from electric lighting or street railway experience, we shall be delighted to give them the wide publicity of our pages; and we seize the opportunity of advising our central station friends to get ready for the interchange of ideas on economical practice at the Niagara Falls convention of the National Electric Light Association in June.

WATER OR FIRE TUBE BOILERS?

ELECTRICAL distribution has stimulated the steam engineer in many directions, and next to the steam engine, the boiler has come in for a good share of the attention of manufacturers of that still indispensable adjunct to central stations not fortunate enough to be situated in the vicinity of a water power. But while the battle of competing steam engine men has been waged along rather narrow lines of differentiation in details, a broad line of demarkation has separated the boiler men. The old return tubular boiler, which has done good service for many years in the well established manufacturing industries, has found itself hard pressed by the water tube boiler in electrical work, in spite of the fact that its cost has thus far been greater than that of its predecessor. It must, we believe, be accepted as an established fact, adduced from the experience of the past, that any piece of apparatus fetching a higher price in the market must possess advantages of some marked character to lead to its general preference over another of less cost. As regards the two types of boilers, the question is still open to debate, whether, properly managed, the efficiency of one over the other is such as to make this factor the predominating one in the choice. There must then be other points of superiority which have given the water tube boiler its present ascendancy in electrical work, at least in America. Its greater immunity from destructive explosions; the readier mode of cleaning and inspection; its greater efficiency in unskilled hands; its quick steaming qualities; its greater capacity for forcing without undue priming—all these are points which the advocates of the water tube boiler have urged successfully and no doubt justifiably. The recent explosion of a set of boilers in the Elmira, N. Y., railway power house called forth a communication in our columns last week from an eye witness who ascribes the disaster directly to the employment of the return tubular boiler. In reply to this criticism a correspondent this week comes to the aid of the older type, but fails, in our estimation, to make a very strong case. We agree with our correspondent that with due precautions, a return tubular boiler may be made as safe as such a type of boiler can be made, but unfortunately that type of boiler carries within it elements of deterioration and danger not found in its rival. It is just here that the precautions usually taken fail of accomplishing their ends. As to the other causes which have made the water tube boiler the favorite in up-to-date electric central stations, we need not enlarge upon them, preferring to leave this to the manufacturers. We are firmly convinced, however, that the water tube boiler has come to stay, and that with the tendency to lower prices which has manifested itself of late, it will make the return tubular boiler a rarity in electric central stations of the future.

TELEPHONIC HOODOOS.

A CURIOUS report comes from Alabama, on good authority, as to the objection of some of the farmers to the long distance telephone wires, on the ground that they are directly responsible, by their physical presence, for the low price of cotton. The craze or superstition has spread even in districts which not long ago voted solidly against gold on the same grievance. Poles and wires have been freely cut down, and one line from Gadsden to Walnut Grove has been badly damaged half a dozen times. It is stated that one farmer has devised a new way of "hitching his wagon to a star" by tying one end of a broken wire to the tail of his cart and then tearing down a consecutive seven miles of the circuit. It does not yet appear, however, that cotton goes up as the wires go down. Perhaps the prevalence of this superstition is exaggerated. We hope so. It reminds us of the prejudice of the Chinese, who pull down the telegraph poles and wires because their shadows are likely to be cast across the cemeteries where their dead relatives lie and because that is prejudicial to happiness in the next world. A similar prejudice prevails among West Indian negroes, but they overcome the hoodoo by hanging empty bottles on the fence of their yam patches.

THE WELLINGTON SERIES ENGINE.

ELECTRICAL engineers have always been as alive to any promised improvement in the utilization of steam as to any advance made in electrical apparatus or its application, and for obvious reasons. The coal bill of an electric light station, while not the largest item of expense, is always of sufficient magnitude to make any reduction in it desirable, and cases could probably be cited in which reckless use of steam has been the millstone which has ground the dividends down to an impalpable condition. Modern steam engineering has made such progress that nothing but crass ignorance or carelessness can account for such a state of affairs in the absence of other factors, but none, we believe, would be more ready to admit the possibility of improvements in steam utilization than steam engineers themselves. Indeed, the very fact that their best energies are devoted to this end is sufficient evidence of the present state of the art. Aside from the general progress in details of construction of engines and boilers, the great advance in steam engineering standing out most prominently is the steady rise in the steam pressure used. The introduction of higher steam pressures has already effected remarkable economies in coal consumption and the highest authorities on steam look for still further advances, so that 300 and 400 pounds pressure per square inch may be expected. As a matter of fact such pressures were used by Perkins many years ago and with success, only minor difficulties having been encountered with it. But it would seem that in connection with high steam pressures, methods of working can be employed which have not thus far been contemplated; or, indeed, that lower pressures can be worked to advantage in a way to increase their thermodynamic efficiency. A noteworthy system of this kind is that embodied in the Wellington series engine, to which we devote considerable space in this issue. In the absence of an actual test of a completed engine, or rather engine system, of the Wellington type, it would be difficult to express an opinion on the merits of this radical departure. Theoretically it unquestionably presents advantages, but even if the cost of the system did not exceed that of the present system of equal capacity, the multiplication of apparatus on the engine side might lead to collateral disadvantages which would militate against it. Thus the question of relative area occupied, cost of attendance, repairs, etc., would have to be taken into account before a final answer could be vouchsafed as to the practicability of the new idea. Nevertheless there is such evident merit a priori in the Wellington system that it is to be hoped that the experiments already begun will be carried out to conclusion.

THE handling of crowds on trolley roads is not a small problem, and at far-famed Coney Island it presents itself in a very pronounced form. The Nassau Electric Railroad Company, in building a new station, have proposed a unique plan, the adoption of which will enable visitors to dispense with the cost and formalities of a regular ocean bath. Last year it was customary to use several gates in order to let incoming passengers off before those leaving the Island could reach the cars. The company was not satisfied with the arrangement, although at the time it could not very well be obviated. President Johnson's plan, however, will attempt to remove the difficulty. It consists in a canal about sixty feet long and eighteen inches deep, which will be constantly kept filled with water up to the level of the tracks. Incoming cars will discharge their passengers on the far side of this canal, and, when empty, will cross to receive passengers leaving the Island. Any passenger who attempts to cross the track before the outgoing car reaches its proper place will do so at the risk of wading through this sheet of water. President Johnson is firmly convinced that this plan will be capable of producing all the good he had in view when he conceived it. All that is necessary is to use salt water, and the 5-cent fare to or from the Island can be advertised as including a dip in the sea gratis.

ONE'S notice is often attracted by handbills and "dodgers" stuck on poles, and it would seem that the advertiser who adopts this method secures a part of the publicity he seeks. But the practice has various disadvantages, not to say dangers, and should be forbidden generally, as it already is locally, in some cities. The practice is very annoying to the men whose duty it is to climb up and down the poles, tearing their garments and scratching their clothes on the nails and tacks which are put in to hold the bills and cards. The companies cannot object to the use of their poles as hitching posts, but cover them with strap iron to prevent them being injured by the horses. That has resulted once or twice in the throwing down of a weak pole by a restive horse, and occasionally a bad ground has added a litle stray excitement; but a further objection to the advertising card nuisance is that it gives a very ragged and disorderly look to the poles.

INDIANAPOLIS is just now very much interested and excited over the new three-cent-fare law which the street railway company refuses to recognize. All along the lines last week were enacted lively scenes in the boarding of the cars by determined three-centers and their ejectment by the company's men when the full five-cent fare was not forthcoming. The act provides for the recovery of civil damages not to exceed $100 for a refusal to accept the fare; and all employés collecting in excess of that amount for a single ride are subject to fine. The company holds the law to be invalid and has retained ex-President Harrison to ask for an injunction against it, in the Federal Court. Savannah, Ga., by the way, has just returned to five-cent fares.

JUDGE BUNDY, an Indiana jurist, ruled a few days ago that he would admit a telephonic talk in evidence. He admitted that he could find no authorities in the books, but was quite willing himself to establish a precedent. A somewhat similar question came up in Boston recently, when it was sought to prove that previous to the terrible gas explosion in the subway, the gas company had been called up and notified from the scene of the trouble. The gas manager said it was not so, but a little blue strip was produced, showing time, places and names of caller and callee. That settled it. It would be an easy thing with the aid of a device like the calculagraph to verify with fair approximation all conversational episodes about which it was desirable that no doubt or question should arise later. Even the body or topic of the conversation could be noted down with little trouble.

HITHERTO thieves on breaking into an empty house have contented themselves with stopping short at the removal of the plumbing pipes. From Dayton, O. it is now reported that some professionals have entered a vacant residence and carried off the electric bells and the wiring. It should not be difficult, and would be highly proper, to connect such a house with the local burglar alarm system, if any exists. A protection of that kind for vacant houses might pay pretty well. Even now it is not unusual.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—VI.

BY JOSEPH APPLETON.

[Copyright, 1897.]

INSTALLATION, CARE AND MAINTENANCE.

(Continued.)

THE capacity of a battery will naturally decrease as the rate of discharge increases; the curve, Fig. 19, shows the capacity of a battery at various rates of discharge. There is one point in connection with the capacity of a battery which is often misunderstood, namely, when discharging a battery at excessive rates, and, consequently, obtaining a smaller capacity, it is thought that the efficiency is correspondingly reduced. Take, for example, a cell having a capacity of 1,000 ampere hours at normal rate; at the maximum or one hour discharge rate the available capacity is about one-half the normal, or 500 ampere hours. It is frequently assumed that the loss in efficiency is in the same proportion as the loss in capacity, namely, 50 per cent., whereas the battery is not really empty, the active material being only partly discharged, but unable to give more effective capacity on account of polarization.

In charging a battery after a discharge at excessive rates it will be found that only the capacity of the discharge plus the usual 10 per cent. excess is required to bring the cell back to a fully charged condition. If during a discharge at excessive rates the discharge is occasionally interrupted for a short period it will be found that the cells will give practically the same capacity as at normal rates, as the rest gives the cells time to recuperate and so avoid polarization.

The use of a recording amperemeter is advantageous during a discharge to indicate what charge will be required, but unless it records not only the amount of current taken out during discharge but the rate at which it is taken out it is of little value to show what capacity remains in the battery. For the same reason it is difficult to construct an automatic switch which will cut out the battery when the voltage during discharge has reached the limit, as the voltage per cell varies with the rate of discharge, and a switch of this type operating entirely by voltage, irrespective of the rate of discharge, would cut out a battery when discharging on high rate long before the capacity had been obtained, simply because the voltage had reached the limit of normal rate.

It is quite as important to take occasional readings with low reading voltmeter and hydrometer on individual cells during discharge, as in charge, in order to ascertain if all the cells are in normal condition. This is preferably taken towards the end of a discharge, when the cells have done considerable work. A battery should never be allowed to stand for any length of time in a discharged condition, as the plates will soon become seriously injured. If it is not possible to fully charge the battery immediately after the completion of a complete discharge, the charge should be continued until the cells are at least half full, in which condition they will not be hurt by standing for a little time.

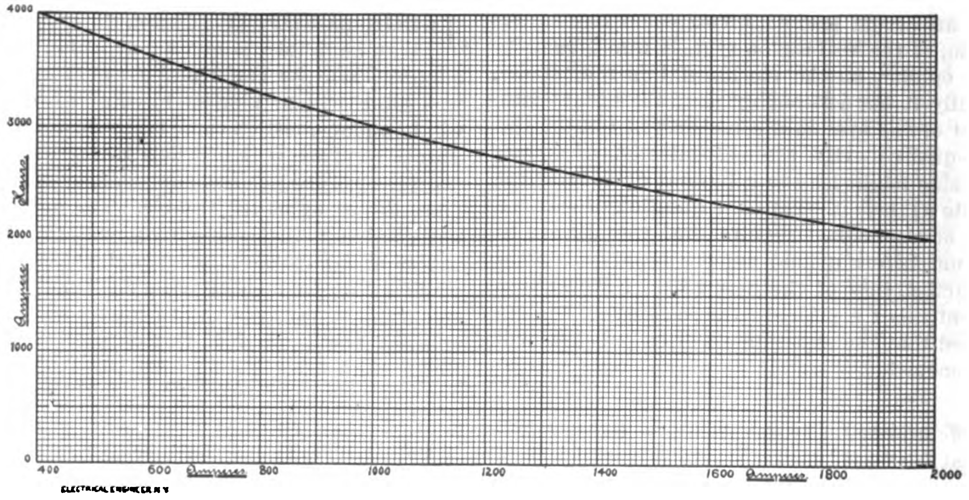

FIG. 19.—CURVE SHOWING VARIATION OF CAPACITY AT DIFFERENT DISCHARGE RATES.

The attention which a properly installed battery requires is very small, not as much as must be given to an engine and dynamo. A careful and regular examination of the cells, together with the observance of the above mentioned precautions, will prevent a battery plant, if properly designed and installed, giving any trouble. If a storage battery always received the same amount of care and attention that other portions of the installation get, there is no doubt as to which would prove the cheapest to maintain.

There is one feature about a storage battery which renders it liable to abuse, namely, the capability of overworking it without its showing visible signs of distress. An engine or dynamo when overloaded will make the fact known by its actions, or perhaps quit altogether; while a battery can be overloaded to practically any extent without showing any ill effects at the time; yet, nevertheless, the injury is done and will eventually make itself felt by the early depreciation of the plates. A cell looks the same, to all intents and purposes, when discharging on practically a short-circuit, as when standing on open circuit, and it is, therefore, necessary to protect a battery against abuse in this way by proper precautions and careful attention.

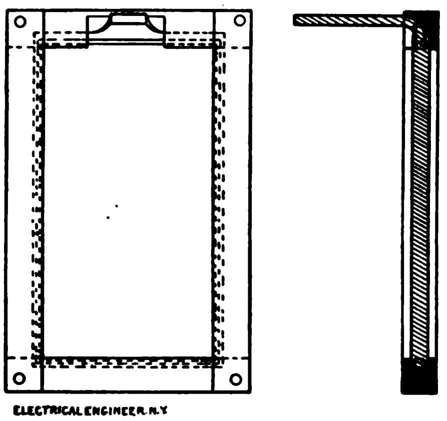

FIG. 20.—CADMIUM TEST PLATE.

With a good modern storage battery very few troubles are liable to occur, provided proper attention is given to keep the regulation of the charge and discharge within proper limits, and if the cells are properly supplied with electrolyte. The only thing likely to happen and cause trouble is the formation of short circuits between the plates, causing the cell to discharge through itself. There are two ways in which short circuits are liable to occur; one, the scaling or peeling of the active material, the pieces which become detached lodging between the plates and forming a circuit between the positive and negative plates, through which the cell can discharge. The other cause of short circuit is the presence of some foreign material which has fallen into the cell.

When a cell is found to be backward in charge and discharge it should be immediately examined for short circuits. The best way to do this, is to probe between the plates with a thin piece of hard rubber; thus removing any material which may have formed a connection between the plates. After a backward cell has been examined and tested in this way, it will require extra charging to bring it up to the same condition as the rest of the battery. This may be done by leaving the cell in circuit for the charge and taking it out for one or two discharges; this is easily done by disconnecting one of the poles before the discharge is commenced, and connecting across the two poles of the adjoining cells. One or two extra charges in this way will soon bring the cell back to its original condition.

A very interesting and accurate test to ascerain the condition of the cell can be made by taking a piece of cadmium, immersing it in the electrolyte and measuring the e. m. f. between it and the positive and negative plates in the cell. By this method it is possible to ascertain at any time during the charge or discharge whether the positive or negative plates are in proper condition or otherwise, thus locating at an early stage any sign of irregularity and trouble. The best form of cadmium test piece is that shown in Fig. 20, consisting of a sheet of cadmium mounted in a hard rubber frame, so that it can be laid on the top of the element. The following readings show the e. m. f. between the cadmium and respective plates in a cell under different conditions:

Cell fully charged and after standing for several hours, e. m. f. between cadmium and negative plate .16 volt, the cadmium being negative to the negative plate.

Cell during discharge at 10 hour rate, two minutes after discharge commenced:

Pos. and Neg. of Cell.	Neg. and Cad.	Pos. and Cad.
2.07	.18	2.25

Same discharge at end of five hours:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.925	.20	2.125

At end of above discharge, but before stopping the current:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.70	.23	1.93

Cell during discharge at three hour rate, two minutes after discharge commenced:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
2.02	.20	2.22

Same discharge at end of one and one-half hours:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.88	.22	2.15

At end of the above discharge, but before stopping current:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.70	.30	2.00

Cell during discharge at one hour rate, two minutes after discharge commenced:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.96	.215	2.175

Same discharge at end of one-half hour:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.83	.26	2.09

At end of above discharge, but before stopping current:

Pos. and Neg.	Neg. and Cad.	Pos. and Cad.
1.60	.33	1.93

During charge the cadmium reads negative to the negative plate until the cell is about full, when the reading should be zero, the charge should be continued in order to get the battery really full, until tne cadmium is .20 volt positive to the negative plate while charging at normal rates. It will be noticed that during charge the cadmium changes its polarity with regard to the negative plate.

In order to obtain the most accurate results the cadmium plate should be shaken occasionally while in the cell to free it from any bubbles of gas which may have accumulated thereon; it should also be rinsed in water every time it is taken out of the electrolyte. A low reading voltmeter is required for this test, and care must be taken with the readings; it is a most reliable and useful test when taken with ordinary care.

Of course, the readings during discharge will vary somewhat with each make of cell, depending upon the proportion of capacity existing between the positive and negative plates; but it is a very easy matter and one well worth undertaking to ascertain by experiment the actual figures for each installation. The figures given refer to a well-known make of cell.

"IT WILL LIVE FOREVER."

An old subscriber was notified by us in the usual way that the time for renewal had run its length and that "the paper would stop." He sent his check in at once and said: "No it won't; it will live forever."

THE NON-FEASIBILITY OF BURGLARIZING SAFES BY ELECTRIC HEAT.

MR. E. G. NOE, superintendent of the engineering department of the General Electric Company, at Chicago, in a letter to A. G. Burton & Son, of that city, furnishes the following interesting discussion of the feasibility of burglarizing safes by electricity. It will be noted that he takes the same view as Prof. Elihu Thomson, Mr. J. J. Wood and Mr. C. O. Mailloux, whose expert opinions were printed in The Electrical Engineer, of March 31. In a lecture before the Kansas City Medical College on March 18, Prof. Lucien I. Blake, of the Kansas State University, gave a practical demonstration of "how impossible it would be for a safeblower to use electricity to drill a hole in a safe." Mr. Noe's letter is as follows:

With reference to our conversation and experiments as to the practicability of burning a hole through a safe by electricity, I beg to say that this is possible, but it requires so much apparatus, and in most cases such a great quantity of power that it makes it practically impossible to be operated by a novice or any one without making special arrangements for it. In fact, I might state that it is utterly impossible for a piece of work to be performed of this kind in the average city of from 60,000 to 70,000 inhabitants; that is, when you are depending upon the facilities of the local lighting companies to secure the necessary energy, as to perform this work it requires an enormous current, and the most economical method that could be employed would be an alternating current, from the fact that what is required is quantity of current at low pressure or voltage. The voltage can range anywhere from 30 to 50 volts, but the quantity of current necessary must be from 300 to 700 amperes. Now, if we take an average case, as talked of, suppose we fix the current necessary at 350 amperes at 40 volts pressure. This will equal 14,000 watts, or practically 19 horse power. Now, in order to convert alternating current energy to this form so that the application would be made easy it would be necessary to introduce a specially made transformer that would transform this energy from a primary voltage of 1,000 or 2,000 volts, as the case might be, to 40 volts secondary current. A transformer of this kind would not be generally found throughout the country, although there are a number of transformers in service with their secondary winding arranged for 50 volts, but they are all of such small sizes that they would not furnish sufficient current to be of any service in an operation of this character. Therefore a special transformer must be constructed and attached. A transformer to do this work would weigh in the neighborhood of 1,300 lbs., which would require considerable labor to cart it about to put it in a convenient place for service. Then from this transformer to the place of operation would have to be run a very large wire, almost one-half inch in diameter, in order to convey the necessary current to do the work without heating up or fusing the wire itself. The connections, and every detail would have to be carefully calculated to insure success, and even with the most skilled mechanics I think the operation of going through a 4-inch or 5-inch safe would fail nine time out of ten. It is rather a dangerous piece of work to undertake, from the fact that 350 amperes of current would make such a tremendous arc that it is hardly safe to handle it. Again, the fusing of the carbon and metal would generate so much gas and smoke that it would be impossible for an operator to remain in a close room or vault to perform his work, as he would be suffocated with gases and smoke before the operation was half completed. Further, it is almost impossible to find electric lines throughout the country so constructed that this amount of power could be taken from them without seriously interrupting the successful operation of the plant, and as all electric lines are equipped with safety fuses or automatic cut-outs, the minute a line would be overloaded or caused to carry or deliver more energy than intended for it, the automatic device in the circuit would open and leave the operator without any current.

The above case covered the most economical operation that could be obtained. Suppose we undertake to get the necessary energy from a street car line? This is a direct current with a primary voltage of about 500 volts, and the form is entirely different than with the alternating current. Now, suppose we require from the trolley line a current of 350 amperes. This 350 amperes multiplied by 500 volts would equal 175,000 watts, which would represent about 255 horse power. It is true that you would not require this high voltage at the point of operation, but you have only one means of reducing this voltage, namely, to introduce a rheostat or resistance coil to cut the voltage down to the amount required. The current, however, you must have. Therefore the difference in energy between that used at the point of operation and that originally taken from the trolley line, is consumed in the rheostat or resistance employed. You will see from this how absurd it would be for any novice to undertake to tap a trolley wire or street car feeder in the street and take 235 horse power from it successfully. Again, suppose we consider the electric current used by a large building in Chicago. For isolated lighting a pressure of 110 volts is usually employed. Therefore if we require 350 amperes from this line we must take it at the voltage of the line, namely, 110.

This would represent 38,500 watts, or practically 52 horse power. Such a connection as this would mean that the operator would be obliged to tap the main wires going from the generator, and the minute this load was put on, the man operating the dynamo and lighting plant would immediately discover that there was some trouble on the lines throughout the house, or that they had turned on the majority of the lights in the building, and would immediately commence to investigate.

More likely, however, the safety cut-outs or automatic circuit breakers would be opened when this amount of power was turned on. This same thing would apply if the wires of a public vender or street service lines were tapped. A fuse or safety device in some part of the line would be opened no doubt and the current shut off. So far as performing a task of this kind from an arc light circuit, that is where arc lights are fed from a regular arc lighting machine, is concerned, it would be practically impossible as the majority of the arc light dynamos only deliver 10 amperes of current, which would be far short of the amount required.

ELECTRIC TRANSPORTATION

AMERICAN STREET RAILWAY FINANCE.—II.

BY E. E. HIGGINS.

AMERICAN street railroads are in possession of their territory by virtue of franchises and charters of varying value. The great majority of them of much less value than corresponding charters and franchises under which steam railroads operate. In a large number of the States of the country, in fact, I think, in nearly all, the charters granted under general railroad laws, or under special railroad laws expressly reserve to the State the right to modify or amend, practically without limit. As far as I know, that right has never been exercised to any serious extent. Lately there has been a slight movement in the direction of appealing to the State authorities to modify or amend the charters in order to accomplish what the municipalities cannot accomplish by the franchises which they have granted; but that is not at all general, and probably will not be resorted to to any serious extent.

The municipal franchises granted to street railways within the last few years are of much less value, with few exceptions, than the earlier ones. The early franchises of New York, Pennsylvania, and one or two other States, are practically for perpetual operation, nine hundred and ninety-nine years' time being allowed for charters and municipal franchises. In Illinois franchises are much less valuable chiefly because they have an extremely short time limit, fifteen years only, by present law, although in a few cases, where the franchises were granted before that law was passed, they are for longer periods. Thirty and fifty year franchises are being granted nowadays far more frequently than used to be the case, and this is having a very serious effect upon the prosperity of street railroads; and, in fact, where the time limit is very short, the people cannot expect and will not receive the service which will be given by a road whose franchises are for long periods, for the simple business reason that companies cannot afford to take chances.

In Massachusetts the condition of affairs is even worse; that State is almost unique in some respects, in that the street railway companies are practically tenants at will of the city and State, and while there is no definite limit placed upon their charter and franchise rights, the practical limit is the willingness of the companies to comply with the demands of the city and State,—a sword constantly hanging over the companies which can be used with great force by the authorities who may say, "If you do not do such and such things we will do such and such things," and they can. As a matter of fact, however, the actual danger in Massachusetts is not great, for the people there have a good common sense way of looking at things, particularly at the rights of property and investment, and I do not think there is much danger to be apprehended by the street railway companies. The police regulations which govern in almost all American cities have been expanded by practice in later years to cover almost every kind of burden. The franchises for the operation of roads by electricity have been used to impose additional burdens of a very serious nature.

It is thought by the newspapers of the country, or at least it is so expressed by them, that the street railways of this country are not paying to the municipalities anything like what the franchises are worth and all sorts of comparisons are made between what is being done across the water in that line, and all sorts of possible contracts with the city are brought up; but many things are lost sight of. It is impossible to generalize on this question of franchises any more than it is on a thousand other street railway matters. There is perhaps no branch of industrial life where generalizing is so unsafe as in street railroading. At the same time this thing is particularly true, that whatever may have been the original conditions under which street railways were granted the rights to operate roads, the conditions to-day are such that they have exceedingly heavy burdens, as heavy I believe, all things considered, as are found in any of the cities of Europe.

These burdens come in a number of ways. In the first place, the introduction of electricity made it necessary to tear up the streets. The cities promptly utilized the power which they had to impose burdens, by obtaining from many of the companies a contract to pave and keep in repair a large portion of the streets through which their lines run. One conspicuous example of this is a certain company operating several hundred miles of track which is obliged to pave and keep in repair perpetually every mile of street, from curb to curb, through which its cars run, and the condition is the more burdensome from the fact that in that particular city the mileage is almost entirely of single tracks. Again, the taxes on gross receipts are now a common feature of municipal finance. This tax runs anywhere from three to ten, fifteen or twenty per cent.; in one case, six thousand per cent., but I believe that road is not operated. (Laughter.) Other burdens are the usual ones of taxes on real estate and personal property, which are always imposed, I think without exception, and car licenses; and taxes on pretty nearly everything where a tax can be by any means imposed, are not uncommon features of street railroading as it is found to-day.

In addition to all this there comes the fact that where a franchise is granted for but twenty, thirty, forty or even fifty years, without any statement in the contract as to what is to occur at the end of the franchise period, the question resolves itself into one of a tax on franchise, because something has got to come out of earnings, and be put aside to take care of any possible changes at the end of that time. For example, a street railroad company has no knowledge as to what will happen at the end of twenty years; it may be obliged to sell its equipment, buildings, tracks, etc., for old stock. It is at the mercy of any company which comes in at the end of that time and bids for the franchise. Now these things are pretty serious, and, taken all in all, you will find that the gross tax paid by street railway companies of the United States to the State and municipal authorities—the municipal authorities as a rule—are a very considerable proportion of their entire receipts.

TRAFFIC.

The theory of the American system of operating street cars is based on the practical wisdom of a uniform fare. I do not suppose the reasons for that were ever argued pro and con and established on a theoretical basis; at the same time, the test of the theory lies in the fact that no attempt has ever been seriously made to change over from the uniform fare rate to the differential rates common in Europe. A differential rate placed on traffic as it is found here, would mean here as it has meant in Europe, that the cities would be condensed in area. As soon as you say to a man that if he goes out three miles away from the heart of the city he must pay six cents, and if he lives within two miles, he must pay but four cents, he begins to figure up at once what the four cents a day excess for the round trip amounts to in a year's time, and in the case of the workers, whose patronage is the backbone of American street railroads, it means a great deal, and in many cases that they will go to tenement house living.

European cities are extremely congested, very small in area, with great population density. American areas on the contrary are large, have always been larger than in Europe, but during the last six or eight years they have expanded in a way which you all know and to an extent which is marvelous. I am looking forward with a good deal of interest to see the results of this outgoing force as it will be shown by the next census. I believe the results will be such as to fill us all with a profound sense of gratitude to the street railway companies, and to electricity as a motive power; for it is only by means of a cheap, flexible, rapid, easily controlled motive power that such a result could possibly be accomplished.

Short distance riding is profitable on a street railroad. Long distance riding is in many of the cities distinctly unprofitable traffic. If the entire passenger traffic of any large city were doubled as to the distance traveled, it would probably mean bankruptcy; or, to put it another way, if all the passengers on the street railroad system of a city were to travel on an average 75 per cent. of the longest distance which they could travel according to the track mileage, instead of perhaps 40 or 50 per cent.—no one knows exactly what the percentage is—it would probably mean very serious financial difficulties. Of course this means that the few who choose to ride the short distances have to pay a part of the fare of the long distance riders. From a socialistic point of view that is perhaps a proper burden; in other words, the many will gain at the expense of the few, and the few who have to ride the short distances may be presumed to be financially able to do so. It may be said that those who live in the outskirts will not be the many, but the few; however, the many gain in the increase of city areas, assessed valuation, reduction of taxes, and the general improvement in the condition of living. The difference between Europe and Ameria—between England and Amrica—is something astonishing. I have not with me figures to show it, but if you will compare cities of the same population—you will find that the street railway mileage in English cities is from one-third to one-half the street railway mileage in American cities, and the traffic, that is, the use which the public make of the street railway service, is anywhere from two to five or six times greater in America than in England.

Now, at the end of the horse railroad period, and at the time when electricity was being introduced, came up exaggerated notions of profits to be derived from electric railroad operation, and exaggerated ideas of what could be done in extending into the suburbs, and the consequence is that coincident with the increase of speed and increase of traffic due to the adoption of better motive power, came an increase in mileage. Competition came in. The old companies which had been operating carefully and conservatively their horse railway properties, found it necessary either to suffer from the effects of competition on parallel lines built by syndicates which were anxious to put in electric railways wherever they could find streets to put them in, or else build the mileage themselves.

ELECTRIC RAILWAYS OF EUROPE.

OUR contemporary, L'Industrie Electrique, has just published a complete list with details of the electric railways now operating on the continent of Europe and in Great Britain. The summary, which we print herewith, shows that Germany is far ahead of any other European country in both the number of electric railways and in the length of mileage, etc. It is interesting to note also that Germany has four roads using storage batteries and France five such roads. Switzerland also makes a very good comparative showing. Considering the number and density of the population of Europe, that continent ought to be a veritable paradise for manufacturers of electric railway apparatus:

	Total Length of Lines in Kms.	Total Power on K. W.	Number of Motor Cars.	Lines with Aer. Cond.	Lines with Undergr. Cond.	Lines with Centr. Rail.	Lines with Accum.	Total No. of Lines.
Germany	642.69	18,963	1,631	45	2	..	4	51
England	109.42	4,670	168	10	1	6	1	18
Austria-Hungary	83.89	2,589	194	7	2	..	1	10
Belgium	34.90	1,220	73	4	1	..	..	5
Bosnia	5.60	75	6	1	..	..	..	1

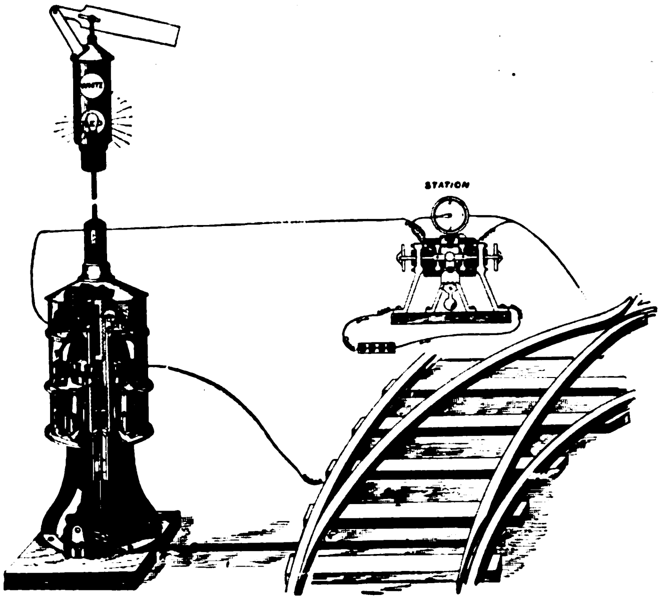
THE SMITH ELECTRIC SELF-LOCKING SWITCH AND SIGNAL APPARATUS.

THE accompanying illustration shows an electric apparatus for operating railroad switches and signals from a point distant from the location of same. Its chief value lies in its positive action and the facility with which it can be worked in a complete system of switches and signals, also making block signal systems efficient and economical. That it is self-locking will be apparent from its construction, thus dispensing with the interlocking devices. As will be seen, the switch rod is operated by a bell crank, the horizontal arm of which engages an upright rod extending to the signal light and semaphore, which it operates, its motion being perpendicular only. This motion is effected by an electric motor fastened to a sleeve, the inside of which is threaded and revolving about the screw upon the perpendicular rod, thus securing a powerful and simple motion, which of itself produces a positive lock.

Above the motor, fastened to the sleeve, is a commutator, consisting of two metallic discs, having radiating and insulated extensions. The upper disc is in continuous contact with a brush communicating with a cut-off, in contact with a line wire. The lower disc has in contact with it a brush connected to the ground wire.

Stationary on the rod and above the screw is placed a rack operating a gear wheel, the circumference of which is equal to the motion of the perpendicular rod up or down. Its shaft carries a crank which operates a pitman, whose far end moves a sliding head housed in a standard in contact with a line wire. Back of this "sliding head standard" is another standard, which is in connection with the brush in contact with the upper disc of the commutator, and from which suspends a swinging arm, weighted at its free end. This arm is in contact with the "sliding head standard," excepting at the last moment of the gear wheel's revolution, when it is tripped by trigger on the sliding head and falls free, thus cutting off the current and stopping the motor. The weight of the ball then compels the arm to fall back again into contact, when it is ready for the next operation of the switch.



SMITH'S ELECTRICALLY OPERATED RAILWAY SIGNAL.

Repetition of the motion is prevented by an instrument in the office or tower from which the motor is operated. This instrument consists of an electro-magnet, excited by the same current and in the same direction as those in the motor at the switch. At each end of this magnet is an armature, either end of which, depending upon the direction the switch is to be thrown, is held against the core as long as the current is continued, but when interrupted by the cut-off (at the track) described above, the armature falls back, impelled by a weighted segment, the movement of which throws the instrument out of contact, in which position it remains until the current is again turned on by the operator. This falling back of the armature is a guarantee that the operation at the switch has been completed. This motion also records the position of the switch at the track, by simply recording on a dial, in figures, the last direction of the current. For switching purposes the motor, commutator and cut-off may be laid horizontally between the tracks, the screw rod directly operating the switch rod. This ingenious apparatus is the invention of Mr. Charles G. Smith, of Pittsburg, Pa.

CHEAP RAILWAY FARES AT SAGINAW, MICH.

A special dispatch from Bay City, Mich., of April 2 says: The war between the steam and electric lines doing business between here and Saginaw is on again, the 20-cent agreement rate having expired to-day. It is the Interurban electric road against the three steam roads. The latter have cut the rate to 10 cents, selling tickets in blocks of ten, good either way on any road, and transferable. The distance between the cities is nearly thirteen miles, making the fare much cheaper than by mileage. The Interurban will meet the cut at once, and May 1 will increase the number and speed of its cars, and endeavor to maintain its business between the cities, which is much larger than that of the railroads.

ROENTGEN RAYS

THE X-RAY PICTURE OF A BONE GRAFT.

BY ORRIN E. DUNLAP.

MEDICAL circles of Western New York have been very much interested in an operation that was performed on F. H. Moir in the Lexington Heights Hospital, Buffalo, some weeks ago. Mr. Moir is the foreman of the calcium carbide works at Niagara Falls, and on Jan. 1 the tibia of his left leg was fractured by the bursting of an air drum. Dr. William H. Hodge and Dr. William C. Cross were called to attend him, and at first there was every probability that the leg would have to be amputated. It was evident that the ordinary methods of instituting a new growth of bone and the proper joining would not be successful. They therefore resolved upon a remarkable operation to save Moir's leg. When all the conditions were right Drs. William Hodge, Dewitt G. Wilcox and William C. Cross performed an operation.

To the two ends of the broken tibia they engrafted a piece of bone from the femur of a sheep. The piece of bone inserted was five inches long, and the ends were placed in the ends of the tibia. The wound was then sewed up and the leg placed in a cast made of plaster of Paris, an opening sufficient to allow of the proper dressing and examination being left.

X-RAY PHOTOGRAPH OF GRAFTED BONE.

Ever since the operation was performed the patient has been the subject of unusual attention, for many physicians watched his condition. The X-ray picture presented on this page was taken just 41 days after the bone had been grafted. Drs. Wilcox, Hodge and Cross are very much pleased with what it shows. It is clear that the sheep's bone has taken life and the process of repair is rapidly going on. It is easy to trace the line of new growth along the graft. This growth is progressing from the two ends, and at each end it is clearly defined. Around the shaft is an organized blood clot, through which numerous bone cells can be traced. It is expected that this clot will, in the course of time, become a bony mass, when the result will be complete. Throughout the trying ordeal Mr Moir has kept up his courage, feeling most hopeful that he will finally have the full use of his injured leg. Naturally, it will take some months yet for the bone to grow so that he will be able to stand on the leg, but it is expected to soon place it in a heavier cast, so that he can move about on crutches. The doctors say there is no doubt of the final success of the operation, the patient's condition being of the best. The operation is remarkable from the length of the piece of bone inserted.

PHOTOGRAPHIC CANDLE POWER OF X-RAY TUBES.

SOME time since, on Prof. FitzGerald's suggestion, writes F. T. Trouton in the London "Electrician," I made an estimate of the number of candles necessary to produce the same photographic effect as a Crookes tube can while emitting X-rays. As no estimate of this kind seems to have been made, it may not be without interest to give ours.

The rays from the tube had to pass through thin cardboard, so that only X-rays acted. They were not, however, seriously diminished by the thickness of cardboard used. Between the candle and the sensitive plate, of course, nothing was interposed.

The method adopted was to arrange time and distance so as to get photographic actions of the same amount from a candle as that got from the X-rays emitted during one "spark" through a Crookes tube of the focus pattern.

From previous experiments (Report British Association, 1896, p. 711), the length of time the X-radiations continued to be emitted was known.

It was assumed for convenience that photographic effect is proportional to time of exposure, and also that the plates used gave consistent and uniform results. Making these assumptions, the "candle power" lay between 1 and 5 for the different kinds of spark used. With the spark as ordinary, and taking its duration at about 1-800th of a second, the mean "candle power" came out to be about 1. On the other hand, when the duration of the spark was curtailed to 1-10000th of a second, by arranging that a parallel spark in air should occur, the "candle power" was greater—as much perhaps as 5.

These values would point to the radiation falling off rapidly in intensity with time during the duration of the spark.

EDUCATIONAL

TEACHING BY CORRESPONDENCE SCHOOLS.

The recent twenty-fifth anniversary of the founding of the Stevens Institute of Technology was the means of bringing together a number of active and progressive mechanical and electrical engineers who are engaged in professional work, as educators in colleges and as editors of technical papers, and as consulting engineers, superintendents of motive power in railway work, manufacturers, draftsmen, etc. Having a common and well founded belief in the efficacy of an education at Stevens, it was natural that some of the chief topics for discussion should be the value of their education, how an education can be best obtained, and of what an education should consist.

As the president of the Correspondence School of Technology was present, it was natural that the work of that institution was made a subject of inquiry by many of the alumni, and it was quite a surprise to many to learn that that institution is furnishing an education not only to many whose previous theoretical training had been very meager, but also to a large number who were college graduates, including graduates from some of the principal technical schools of the country. The fact was developed that the Correspondence School of Technology has many students ranging from 25 years of age up to 55, and among whom are men of very considerable professional attainments, and occupying good positions both in professional and business circles, and who found that it paid to review work which they had had in their earlier days and also to take up new studies and be brought up to date by means of the opportunities offered by the above school. Some of these men are technical graduates, whose college courses had trained them for a specialty quite different from that into which they had drifted; some are civil engineers, who have taken up mechanical engineering, and vice versa, and very many of both having gone into electrical work. In some cases men have even been prepared at college for the course which they are now reviewing in the Correspondence School; the review is valuable, and at the same time many practical suggestions of great value to them in their work are obtained.

A specialty of the school is also its course in advanced mathematics, which includes differential and integral calculus. This course is taken by quite a number of professional men and also by instructors in schools and colleges.

Although, as above stated, a large portion of the students of the school are men of mature years, nevertheless, there are quite a number of young men taking the complete course with the intention of afterward going to college, a course in the school enabling them either to devote less time to their college course, or to devote more time to laboratory work when in college. To those who know of the professional standing of the instructors in the school it is not surprising to learn of its success along professional lines; nevertheless, it is gratifying to know that the work has been recognized, and its students attest its value.

SOCIETY & CLUB NOTES

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 115th meeting of the Institute wil be held at 12 West Thirty-first street, New York City, on Wednesday, April 21, 1897, at 8 o'clock p. m. A paper will be presented by Dr. A. C. Crehore and Lieut. Geo. O. Squier, entitled "The Synchronograph; A New Method of Rapidly Transmitting Intelligence by the Alternating Current." The paper will be illustrated by lantern slides, and advance copies will be distributed at the meeting.

A meeting of Western Members will be held at the Armour Institute, Thirty-third street and Armour avenue, Chicago, at the same date and hour (April 21, 8 p. m.) where the paper will be read by Dr. Frederick Bedell.

The next meeting of the Institute will be the annual meeting for the election of officers, the reception of the yearly report, etc., which will be held at 12 West Thirty-first street, New York City, May 18. The general meeting for the reading and discussion of professional papers will be held at Greenacre-on-the-Piscataqua, Eliot, Me., beginning July 26.

PERSONAL

MR. E. G. ACHESON.

On Saturday, April 17, Mr. E. G. Acheson, president of the Carborundum Company, of Niagara Falls, and the discoverer of the new abrasive which has won such popularity, sailed for Germany to establish a plant for the manufacture of carborundum in that country. He was accompanieyd by Mr. James Hipple, who has been associated with Mr. Acheson for several years and is thoroughly familiar with the process of making carborundum. When he sailed, Mr. Acheson expressed the opinion that they would be absent at least three months. It is expected that the plant in Germany will be about the size of the plant now in operation at Niagara Falls, which now uses 1,000 horse-power. The idea of erecting the plant in Germany is to protect the German patents, and Mr Acheson could not say whether they would simply make the carborundum, or whether they would also manufacture wheels and the various other articles made from the abrasive. He expressed the belief that they would sell the carborundum to other parties who would manufacture the several articles. The law in England is not so stringent as to the erection of factories and the process of manufacture in order to protect the patents granted by that country; and it is to supply the English market, as well as the increasing American demand, that the Niagara Falls factory is to be enlarged. The Niagara Falls plant has been a great success, and on May 17, or thereabouts, the Canadian plant will be in operation at Niagara Falls, Ont.

MR. J. D. REID, U. S. Consul at Dumfermline, Scotland, celebrated the close of his seventy-eight year by playing one game of golf, and hailed his birthday by playing another "in quite a gale on the Ferryhills." God bless the Grand Old Telegrapher! May he indulge in a birthday foursome these many years to come.

PRESIDENT SAMUEL INSULL, of the Chicago Edison Co., was an Eastern visitor last week.

MR. J. W. GODFREY, general manager for Habirshaw wires and cables, has just returned from a long trip, during which he went as far as California. He reports general business as better and his own trade as booming. Dr. Habirshaw is still in Europe.

MR. W. F. LEWIS, manager of the Evanston exchange of the Chicago Telephone Co., eloped to Milwaukee with Miss F. C. Richards, niece of a banker, and married her there. The banker was surprised, but a reconciliation has been happily effected, and the exchange is in regular operation.

LEGAL NOTES

THE SCOPE OF THE ROOSEVELT TELEPHONE SWITCH DECISION.

WE have received from the Western Telephone Construction Co., of Chicago, the subjoined statement in regard to the recent decision by Judge Grosscup noted in our last issue:

The Western Telephone Construction Company recently scored another victory over the Bell Company by its defeat of the Western Electric Company in the suit brought by the Western Electric Company against the Western Telephone Construction Company for alleged infringement of the famous Roosevelt patent, No. 215,837. For many years back the Roosevelt patent has been considered the fundamental automatic telephone switch patent, and so broad and sweeping were its claims that it was supposed to cover every conceivable form of switch for changing from the calling to the talking circuits, and vice versa, by the mere act of taking the receiver from, or replacing it on, its point of support. So much faith did the Bell authorities have in the strength of this patent that they paid Roosevelt and his heirs a royalty of ten cents on every hook switch manufactured by that company during the life of the patent, and said royalty amounted in all to over $30,000.

The devices used by the Western Telephone Construction Co., which were claimed by the complainants to infringe the Roosevelt patent were not only their old form of semi-manual switch, where the hook had to be pulled own after hanging the receiver upon it, but also on their automatic form of hook switch, similar to that which they are now turning out, where the only movement necessary to operate it is to remove the receiver from, or replace it on, the hook.

Judge Grosscup, in his decision, refers to the previous art which disclosed means for cutting the telephone and call bell alternately, in circuit, by means of a switch operated manually. This decision, although it does not affect the general public directly (the patent having expired by actual limitation) is very significant. It, and the decision on the Watson switch hook patent, which latter was handed down by Judge Showalter, of the same court, a few weeks ago, shows conclusively the attitude that the courts are likely to take in the consideration of the broad patents for auxiliary telephone apparatus owned by the Bell Company; and it also shows that the public have long been suffering needlessly at the hands of the great monopoly.

The case was tried by Barton & Brown for the complainants, and by Stanley S. Stout for the defendants. The Judge held that the Roosevelt patent covered purely an automatic switch; one which acted without the volition of the operator, and that it did not cover any switch which required any manual operation at all, or required the removal or replacing of the telephone from its point of support.

HARRISON INTERNATIONAL TELEPHONE COMPANY.

Judge Grosscup, in the United States Circuit Court, in Chicago, has declined to appoint a receiver for the Harrison International Telephone Company on the bill of several stockholders. He based his refusal to interfere on the ninety-fourth rule of the court, which requires stockholders who claim fraudulent conduct on the part of a corporation to first seek redress of the wrongs through the official board of the corporation. This was not done in the case of the complainants.

$15,000 FOR PERSONAL INJURIES.

The judgment obtained by Lawyer Frank Dudley Tansley in favor of his client, Chas. H. Blair, against the New York Electric Equipment Company for $15,000 in the United States Circuit Court and appealed to the United States Circuit Court of Appeals, has been affirmed by the latter. Blair was injured in April, 1895, in the New York Life Insurance Building by a pipe falling from a bundle being raised by the employés of the Equipment Company. The precaution of using bagging on the end of the bundle was omitted. Blair, as the result of the injuries he sustained, became paralyzed on his right side. He had been warned not to omit the precaution.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Dynamos and Motors:

ARMATURE REACTION DUE TO MAGNETIC WHIRLS. —By Ch. Westphal. The question is discussed to what extent whirls influence the electric conditions in an alternator; this is principally of value in connection with the construction of diagrams. It is found that these currents increase the armature reactions.—"Elek. Zeitschr.," March 11, '97.

Electro-Chemistry:

REFINING BISMUTH BY ELECTRICITY.—It is reported that B. Zakorski has produced a satisfactory method for refining bismuth. He employs impure bismuth as an anode in an electrolytic tank with a solution of nitric acid as an electrolyte. Carbon, pure bismuth or platinum may be employed as the cathode. Pure bismuth is deposited on the cathode, from whence it falls or may be asily removed. It is then washed in dilute nitric acid, dried and fused.—"Elec.," March 24, '97.

Electro Therapeutics:

MOTOR GENERATOR IN THERAPEUTICS.—By Edwin W. Hammer. The writer explains the advantages and disadvantages of the different kinds of currents that are employed in electro-therapeutics and also the various machines that have been introduced into practice.—"Elec. Journ.," March 1, '97.

Lighting:

SOME FACTS RELATING TO GAS AND ELECTRICITY. —By J.F. Seamon. The writer gives a comparison of the developments of gas and electricity for the last twenty years, stating the uses that they have had and how they stand at the present time.—"Am. Gas Lt. Journ.," Feb. 15, '97.

GAS ENGINES FOR ELECTRIC LIGHTING.—This article relates to the question whether it is advisable to operate a dynamo in connection with a gas engine, pointing out one or two serious difficulties that arise, the main one being the irregular way in which a gas engine runs.—"Prog. Age," March 1, '97.

METHODS OF CHARGING FOR ELECTRICITY SUPPLY. —By R. P. Wilson. An article relating to the different methods employed for charging consumers for the amount of current they use, pointing out the advantages and disadvantages of the various systems.—"Electricity," March 24, '97.

Measurements:

INSULATION MEASUREMENTS.—By Rudolf Kutsch. The writer of this article prepared an instrument (sketches and instructions for same accompany the description), whereby he measures the insulation between any two or three wires on a high potential system. He tries to determine the resistances of the principal sections as well as of the system as a whole.— "Elek. Zeitschr.," March 11, '97.

Miscellaneous:

NOTE ON THE DIELECTRIC CONSTANT OF ICE AND ALCOHOL AT VERY LOW TEMPERATURES.—By Profs. James Dewar and J. A. Fleming, FF. R. S. The most important section of this paper consists of four tables, including the determinations of several observers. (1) Dielectric constant of water by various methods. (2) The electrical refractive index of water for electric waves of various wave lengths. (3) The dielectric constant of ethyl alcohol, and (4) the electrical refractive index of ethyl alcohol for the electric waves of various wave lengths.—Lond. "Elec.," April 2, '97.

PREVENTION OF FIRES DUE TO LEAKAGE OF ELECTRICITY.—By Fred. Bathurst. A comparison between electric wiring and gas piping, pointing out necessary precautions to be taken in both cases as regards materials, etc. The statement is made that fires are often prevented by leakage currents blowing fuses.—"Am. Gas Lt. Journ.," April 12, '97.

Power Transmission:

ELECTRICITY AT THE BLAST FURNACE.—This article shows how the electric motor is taking the place of other kinds of machinery in running cranes, hoists and the like.— "Am. Man.," March 19, '97.

ELECTRIC HOISTS.—Description of a number of mines that have introduced electric hoists, showing the great saving in operating expenses and the advantage that they can be controlled from most any point.—"Age of Steel," April 3, '97.

Railways:

ELECTRIC SELF-LOCKING SWITCH AND SIGNAL APPARATUS.—Illustrated description of a new system, whose chief value is said to be in its positive action and the facility with which it can be worked.—"Am. Man.," April 9, '97.

THE NEW HEILMANN LOCOMOTIVE.—Abstract of an article by F. Drouin. A few of the important features of this locomotive and results of efficiency tests. The total efficiency of the locomotive is 73.4 per cent., while the commercial and available efficiency has been worked as follows:

The power absorbed by the locomotive itself can be deduced from the efficiency of the locomotive as an apparatus for traction; that is to say, the relation between the power available at the drawbar and the I. H. P. of the cylinder. This efficiency naturally varies with the profile of the line, the weight of the machine, the speed, etc. Assuming that the locomotive is running at full load on the level, at 62 miles an hour, with a total weight of 132 on the locomotive (this weight assumes that the engine, which weighs about 120 tons, is followed by a tender which can carry 20 tons of water, that this stock is half exhausted), the effective horse-power absorbed by the machine would be 342, and hence the power available at the drawbar would be 664 horse-power. The efficiency of the locomotive is then 48.4 per cent. 660 horse-power at the drawbar should draw 250 tons of ordinary rolling stock (or 350 tons of rolling stock on bogies) at 62 miles an hour.—Lond. Elec., April 2, '97.

OVERHEAD CONSTRUCTION FOR SUBURBAN LINES.— By J. F.Macartney. In laying out the overhead work the conditions to be taken into consideration in laying out feeders are as follows: (1) Number, weight, speed and headway of cars. (2) Grades and curves. (3) Distance in feet from source of power to a center of distribution. (4) Cost of power in station, which determines the amount of power which may be economically lost in the feeder. Further on a calculation shows that one mile of span work, poles 110 feet apart, allowing for one curve and one turnout, may be constructed for $1,200.—Str. R'y Journ. Elec. R'y Gaz., April, '97.

STREET RAILWAY SYSTEM OF SYRACUSE, N. Y.—The entire street railway system in the above named city has been completed and is explained in detail with illustrations of power house, trolley line, feeders, etc.—Str. R'y Journ., March, '97.

SAFETY DEVICE FOR TROLLEY LINES.—Before Franklin Institute. By L. G. Rowand. This device consists of a differentially wound magnet with the same amount of current running through both sections, so that the magnet remains neutral. If the trolley line which is in series with one winding should break, the other winding would energize the magnet and draw up an armature, which, acting as a circuit breaker, would disconnect the trolley line from the cable or main supply wire. Another device in connection with this sends an alarm to the power house or repair station, giving the number of the trolley section that is disabled so that the repair wagon can immediately start for the scene.—Electricity, Mar. 24, '97.

Roentgen Rays:

THE PRACTICAL VALUE OF THE ROENTGEN RAY IN THE ROUTINE WORK OF SURGICAL OFFICE PRACTICE.—By H. M. Richardson, M. D. A communication in which the writer points out the value of the Röntgen ray for purely diagnostical purposes, mentioning many examples which have come up in his practice.—"Elec. Journ.," March 15, '97.

Telegraphy, Telephony, Etc:

SPAN OF TELEGRAPH WIRES OF IRON AND BRONZE. —By H. Dreisbach. Data for expansion and contraction as well as increase and decrease of elasticity with varying temperature, derived from practice, are given and as a result it is found that iron or bronze wires may be put on the same poles without causing undue strains, since the curves of span remain approximately parallel.—"Elektr. Zeitschr.," March 11, '97.

ACCUMULATOR PLANT IN THE MAIN TELEGRAPH STATION AT PARIS.—By J. A. Montpellier. Diagrams showing the methods of connection, and description of plant with details concerning the manipulation.—"Elek. Zeitschr.," March 18, '97.

Transformers:

OIL INSULATION IN TRANSFORMERS.—The problem of utilizing oil insulation is discussed, editorial reference being made to Prof. Garnett's experiments, which show that oil has the tendency of absorbing water, and in many cases where transformers are left open on top, cause a short circuit in the transformer wire.—"Elektr. Zeitschr.," March 18, '97.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 6, 1897.

Batteries:—

COMPOSITION OF MATTER FOR MANUFACTURING BATTERY-CASES, ETC. W. Morison, Montclair, N. J., 580,139. Filed Nov. 24, 1896.

Consists of asphaltum, gutta-percha, asbestos and sulphur in suitable proportions.

Conductors, Conduits and Insulators:—

CABLE ATTACHING DEVICE. J. Stephens, Forest City, Pa., 580,165. Filed Nov. 13, 1896.

Comprises a pair of members arranged to open and close, hollowed out inside to hold a coiled portion of the cable, and means for locking the sections together.

Distribution:—

ELECTRICAL TRANSFORMER PLATE. R. W. Blackmore, Peoria, Ill., 580,206. Filed Nov. 20, 1896.

A transformer plate in which are two openings for receiving a given coil of the transformer, and provided with two cuts, one communicating from one hole to the outside edge of the plate, and the other communicating from one hole to the other hole, and both cuts lying in a rectilinear line, which coincides with an edge of each hole.

Dynamos and Motors:—

ARMATURE CORE. S. H. Short, Cleveland, Ohio, 580,011. Filed Jan. 19, 1897.

An armature-core built up of laminae and having spacers interposed between the laminae and separated therefrom.

MAGNETO AND DYNAMO GENERATOR. C. H. Wade, J. Moores, and H. O. Farrell, Manchester, Eng., 580,180. Filed Jan. 5, 1897.

Comprises a contact block in combination with a series of terminals connected with sections of the armature coil, the block or device being moved over the terminals by centrifugal action.

ELECTRIC BRUSH HOLDER. T. J. Loughridge, Oshkosh, Wis., 580,144. Filed June 1, 1896.

A clamp for holding electric brushes while being trimmed.

Electro-Metallurgy:—

PROCESS FOR PRODUCING METALLIC CYANIDS. C. Kellner, Vienna, Austria-Hungary, 579,988. Filed Feb. 11, 1896.

Consists in decomposing a suitable nitrate or nitrite by the heat of and in an electric arc between carbon electrodes.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. W. J. Davy, London, Eng., 580,256. Filed Dec. 9, 1895.

Feed mechanism.

Miscellaneous:—

KEYBOARD ATTACHMENT. H. W. Shonnard, New York, 580,010. Filed Aug. 24, 1895.

Adapted for musical instruments in keyboard attachments on which a key striker is actuated by electro magnets.

ART OF AND APPARATUS FOR GENERATING AND DISTRIBUTING MUSIC ELECTRICALLY. T. Cahill, New York, 580,035. Filed Feb. 4, 1896.

The tones are produced by the translation of electrical vibrations.

ELECTROMAGNETIC COIL. W. E. Harrington, Philadelphia, Pa., 580,276. Filed Jan. 15, 1896.

An electromagnetic coil having radially deep and axially narrow composite windings, said composite windings being made up of two or more separate bars, each of substantially rectangular form connected in multiple and the outer ones being coiled on those next within to form the composite windings.

APPARATUS FOR MANUFACTURING OZONE. C. J. Yarnold, London, Eng., 580,244. Filed Aug. 20, 1896.

Compresses a casing provided with passage ways for the gaseous fluid, expansion chambers at the ends of the generator of greater cross sectional area at the middle than at their ends.

URINAL. F. C. Rees, Hampton, Va., 580,329. Filed Feb. 27, 1896.

Consists of a receptacle normally concealed beneath a flooring, a trap door obscuring the receptacle and electrically operated means for automatically and simultaneously opening the trap door and elevating the receptacle.

Railways and Appliances:—

ELECTRICAL RAILWAY SYSTEM. W. Robinson, Boston, Mass., 580,057. Filed Jan. 21, 1895.

Sectional conduit system.

CONDUIT SYSTEM FOR ELECTRIC RAILWAYS. A. Q. Babendreier, Washington, D. C., 580,246. Filed Oct. 26, 1896.

Comprises an insulator support embodying a casing provided with outwardly projecting lugs at each end, brackets fixedly secured to the lugs, and means for supporting the brackets within the conduit.

Switches, Cut-Outs, Etc.:—

ELECTRIC PUSH-BUTTON. R. L. Moore, Statesville, N. C., 580,092. Filed June 30, 1896.

Consists of a cap carrying contact devices, and fasteners comprising pieces of wire which are bent into eyes and secured to the cap, the fasteners being adapted to receive securing devices.

MAGNETIC CIRCUIT BREAKER. W. E. Harrington, Philadelphia, Pa., 580,277. Filed Jan. 15, 1896.

The cut-out switch is actuated to sever connection with the circuit in which it is placed with a rapidity bearing an inverse ratio to the amount of excessive current flowing through the circuit.

ELECTRICAL CUT-OUT. H. C. Jones, New York, 580,320. Filed Aug. 12, 1896.

Details of construction.

ELECTRICAL CIRCUIT CLOSER. O. F. Allen, Springfield, Mass., 580,339. Filed Dec. 18, 1896.

Comprises two electrodes normally out of contact, coated with easily fusible conductive metal, in combination with a receptacle adapted to hold the molten fusible metal in contact with both electrodes.

Telephones:—

MAGNETO ELECTRIC GENERATOR. W. Gillette, New York, 580,975. Filed July 31, 1895.

Comprises a series of permanent magnets, with their extreme ends presented to the face of the armature with a shunting device, a shaft driving a train of geared wheels.

TELEPHONE CIRCUIT. J. S. Stone, Boston, Mass., 580,166. Filed June 26, 1895.

The current is supplied to the transmitters from the central station.

ATTACHMENT FOR OPERATING TELEPHONE CALL BELLS. H. W. Libbey, Boston, Mass., 580,335. Filed Sept. 19, 1893.

A lever secured to the casing of the instrument one end of which is over the push-button, and the other end having a block with a beveled hole through it, a cord passing through the block, and wound around a spool adapted to rotate the bell shaft when the cord is pulled out.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 13, 1897.

Alarms and Signals:—

CIRCUIT CONTROLLING APPARATUS. F. M. Brinkerhoff, Matteawan, N. Y., 580,519. Filed March 10, 1896.

Comprises a switch jaw and a moving member actuated through suitable connections by the passage of a train.

BURGLAR ALARM SYSTEM. D. M. Munro, Gaithersburg, Md., 580,552. Filed May 25, 1896.

Consists of a normally closed night circuit through the entrances, a relay, and lines therefrom, a normally open local circuit adapted to be closed by the relay, a switch in the night circuit, and an independent switch in the day circuit.

ALARM LOCK. J. H. Doscher, Brooklyn, N. Y., 580,680. Filed March 26, 1896.

The insertion of the key into the lock causes an electric bell to be rung.

Batteries, Primary:—

GALVANIC BATTERY ELEMENT. G. Laura, Turin, Italy, 580,497. Filed Feb. 27, 1895.

A diaphragm for double liquid cells, consisting of a paste composed of a pulverized plant of the order of Malvaceae and a conductive substance, as a solution of sodium chloride.

GALVANIC BATTERY. R. W. Gordon, Boston, Mass., 580,523. Filed Oct. 1, 1894.

A solution of caustic soda is used for the exciting fluid and black oxide of copper as the depolarizing agent.

Batteries, Secondary:

ELECTRODE FOR SECONDARY BATTERIES. F. W. Schneider, Triberg, Germany, 580,428. Filed Aug. 15, 1896.

Comprises a supporting frame, electrodes consisting of carriers having a perforated top and an imperforated bottom and an open-top trough-shaped receptacle within them supporting the active material.

Connectors, Conduits and Insulators:—

ART OF INSULATING ELECTRIC CONDUCTORS. A. J. Robertson, Chicago, Ill., 580,584. Filed Sept. 6, 1895.

Consists first in hermetically inclosing an electric conductor in a hollow conduit and then exhausting and drying the air in the conduit.

INSULATOR AND INSULATING CONDUIT OF TUBING FOR ELECTRICAL PURPOSES. F. G. Treharne, Lainishen, Eng., 580,628. Filed Oct. 28, 1896.

Consists of silicates impregnated with electrical non-conducting cement.

Dynamos and Motors:—

SYSTEM OF CONSTANT CURRENT GENERATION AND REGULATION. T. H. Hicks, Detroit, Mich., 580,490. Filed Nov. 5, 1894.

Comprises two electrical generators with a work circuit, each of the generators having two sets of field magnet coils; one field coil of each generator and the work circuit being connected in linear series with each other, one field coil of one generator being arranged in multiple arc with the work circuit, and the remaining field coil being supplied with current from the other generator.

Electro-Metallurgy:—

ELECTRIC DEPOSITING DEVICE. J. W. Conchar, Dubuque, Iowa, 580,451. Filed June 22, 1896.

Consists of a tank and fixed rods for the hooks which support the articles to be deposited upon in the bath, mounted above the tank, combined with an endless belt.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. A. C. Seibold, Mount Vernon, N. Y., 580,734. Filed May 11, 1892.

The electrodes are enclosed in a small normally air-tight casing, provided at its ends with closures engaging the electrodes, one or both of which constitute valves.

ELECTRIC SEARCH LIGHT. R. M. Hunter, Philadelphia, Pa., 580,836. Filed Aug. 1, 1891.

Employs means to cause the reflector to be vibrated for the purpose of causing the beam of light to be vibrated at its distant end with a sufficient rapidity to continually illuminate an area greater than would be otherwise illuminated.

Measurement:

ELECTRICAL INDICATING WATTMETER. T. Duncan, Fort Wayne, Ind., 580,384. Filed Dec. 3, 1896.

Comprises a plurality of field coils whose magnetic axes cut each other at right angles, and a volt coil pivotally mounted therein and having its magnetic axis at right angles to one of the magnetic axes of the field coils and actuated by them.

ELECTRIC RIVETING APPARATUS. E. Thomson, Lynn, Mass., 580,475. Filed June 14, 1889.

Comprises a transformer whose secondary is a bar, a metallic anvil secured to one terminal bar, and a metallic heading tool mounted opposite to the anvil upon the other terminal of the bar.

NON-INDUCTIVE ADJUSTABLE CARBON RESISTANCE. S. P. Blackmore, Johannesburg, South Africa, 580,657. Filed Sept. 23, 1896.

Applicable to lightning arresters for use with electric light and transmission of power conductors.

ELECTROMAGNETIC LOCKING DEVICE. E. J. M. Scheeren, Denver Col., 580,820. Filed Oct. 13, 1896.

Appliance for locking doors, whereby the movement of the spring-held bolt by the knob is prevented by pressing a push button.

ELECTRIC HOIST. J. A. Lounsbury, Chicago, Ill., 580,457. Filed July 13, 1896.

Comprises a motor frame of annular form having an integral extension providing a bearing for a sheave shaft.

Railways and Appliances:—

SUPPORTING MEANS FOR ELECTRIC RAILWAY SUPPLY CONDUCTORS. H. P. Davis, Pittsburg, Pa., 580,380. Filed June 10, 1896.

Comprises a plate provided with a plurality of radial grooves, a cap plate and means for clamping the conductors between the plates.

SUPPORTING MEANS FOR ELECTRIC RAILWAY SUPPLY CONDUCTORS. H. P. Davis, Pittsburg, Pa., 580,381. Filed June 10, 1896.

Consists of a bar having a longitudinally grooved upper edge and a curved lower edge, and provided at one side with a perforated ear.

ELECTRIC HEADLIGHT. R. P. Schwerin, San Francisco, Cal., 580,557. Filed Sept. 30, 1896.

Adapted to be carried by electric cars.

TROLLEY CATCHER. R. Orme, Racine, Wis., 580,708. Filed July 23, 1896.

Comprises a gravity actuated weight to which the cord is attached, a catch releasably supporting the weight, and means by which the catches are actuated by the raising of the weight to automatically release it.

ELECTRIC LOCOMOTIVE. W. S. Elliott, Pittsburg, Pa., 580,598. Filed June 27, 1896.

A truck frame comprising an upper motor and car supporting framework, and friction-driving mechanism supported upon the wheels, and a lower framework provided with housings and car axle boxes mounted in the housings, and means for adjusting the housings toward or from each other.

Switches, Cut-Outs, Etc.:—

MEANS FOR CONTROLLING ELECTRIC CURRENTS. E. Ellicott, Chicago, Ill., 580,663. Filed Aug. 6, 1896.

Adapted for use in stage lighting.

ELECTRIC SWITCH. T. H. Brady, New Britain, Conn., 580,678. Filed Jan. 9, 1897.

Four-pole spring switch.

Telegraphs:—

PRINTING TELEGRAPH. H. Kreusler, Kreischerville, N. Y., 580,617. Filed March 6, 1896.

Comprises a switching arm, a keyboard, a screw shaft for swinging the arm, a local circuit controlled by the keyboard for controlling the arm, the keys of the keyboard being so located as to arrest the motion of the arm.

Telephones:—

TELEPHONE TRANSMITTER. A. Stromberg and A. Carlson, Chicago, Ill., 580,434. Filed Nov. 9, 1896.

Comprises a diaphragm, a sheet of wire gauze mounted upon its rear face, a sheet of wire gauze mounted opposite the sheet of gauze upon the diaphragm, and granular carbon between the sheets of gauze.

OBITUARY

J. J. STORROW.

Mr. J. J. Storrow, the well-known attorney of Boston, who recently represented the Venezuelan Government before the commission appointed by President Cleveland to determine the boundary line between Venezuela and British Guiana, died suddenly on Thursday afternoon, April 15, in the new Congressional Library Building, Washington. Mr. Storrow was on his way from Florida with his family. He left his family at Fortress Monroe and went to Washington on business before the Supreme Court. He was looking through the new library building when he suddenly fell to the floor and died in a few moments.

He was one of the most eminent lawyers in Boston. He was born in that city in 1837, the son of Charles S. Storrow. He graduated from Harvard in 1857, and three years later was admitted to the Suffolk Bar. He early acquired a reputation as a patent lawyer, and was chief counsel for the Bell Telephone Company from 1879 until his death. His strong and able telephone arguments are among the classics of electrical litigation.

When, in November last, opposition arose in some quarters in Venezuela against the treaty, Mr. Storrow accompanied Señor Andrade, Minister to the United States, to Caracas, and was largely instrumental in bringing the treaty into favor there and securing its acceptance. He returned to Washington on December 28.

He leaves two sons, J. J. Storrow, Jr., and Samuel Storrow, the former just chosen to represent Harvard as Walter Camp represents Yale in matters of dispute between the universities. The deceased leaves a brother, Charles Storrow, and a sister, Mrs. Eben Dale.

MR. JOHN KENNAN, father of Mr. George Kennan, the noted Siberian traveler and writer, has just died at Montclair, N. J., aged 93. He was for forty years a resident of Norwalk, O., and in charge of the Western Union office. He was the oldest telegrapher, it is said, in the United States.

MR. B. ECKHOUT, member of the electrican engineering firm of H. D. Bayne & Co., has died suddenly of hemorrhage of the lungs at Colorado Springs. He was born at Glasgow, Scotland, and was only 29 years of age.

THE STOCK MARKET

WHAT WILL THE EFFECT OF WAR BE?

At last Greece and Turkey are officially at war, having been so in an unofficial but very practical way for a month past. The effect on the various markets is now to be seen. As far as can be judged, the immediate effect on American products must be excellent. Wheat went up 5 cents Saturday and bids fair to rise further this week, with corn in close attendance. There are few things, even to munitions of war, that this country cannot furnish to the European combatants. When we come to securities, even our worst show up pretty well as compared with Greek and Turkish "obligations." At the same time, there is likely to be a drawing in of credits everywhere by European bankers, and that will affect prices adversely. One can never tell where an ugly little war like the present will end.

The tremendous floods through a large section of the Southwest have checked trade, and there is a prospect that this year's cotton crop will be greatly reduced there. On the other hand, farmers are happy over the prices of cereals. Business failures last week fell off to 195 as compared with 244 a year ago. That tells how things are going.

With sales of only 6,445 shares, General Electric closed last week at 30⅞. Western Union, on 13,104 shares, closed at 80⅝. American Bell telephone rose from 218½ to 224. It may be noted that General Electric bonds, deb. 5s, sold at 96.

REPORTS OF COMPANIES

NATIONAL CONDUIT AND CABLE CO.

The National Conduit Manufacturing Company and the National Underground Cable Company have been consolidated under the name of the National Conduit and Cable Company. The new organization is the sole owner of patents for paper insulated wires and cables for telephone and telegraph, electric light and power service, and wrought iron cement lined tubes for electric subways. It also contracts for complete subway systems. The mills of the new company are at Hastings-on-Hudson, with its New York office in the Times Building, and branch offices in Boston, Chicago and Philadelphia. The officers are Edward S. Perot, president; C. Gallagher, vice-president; Jas. P. McQuaide, treasurer, and Geo. J. Jackson, secretary.

CHASE CONSTRUCTION CO.

The Chase Construction Company, of Detroit, Mich., have just been incorporated, with an authorized capital of $25,000. The company will devote itself to construction and equipment of central station lighting, electric railways, steam and water works plants, having just secured a contract to build the electric railway running between Cleveland and Lorain, O., for the Lorain and Cleveland Electric Railroad Company, which is to be completed by June 1. The officers of the company are: George E. Fisher, president and treasurer; O. D. Chase, secretary and chief, engineering department, and E. N. Chase, vice-president and superintendent of construction. The active men in the company are pioneers in the electrical business. O. D. Chase, whose name the company bears, was electrician and superintendent of the Commercial Electric Engineering Company, while George E. Fisher was its business manager. During the term of the Commercial Company's existence, they installed 56 central station lighting plants and 167 isolated plants, in addition to a large volume of the other electrical work. The Chase Construction Company have secured the services of E. F. Mann as superintendent of railway construction, a practical man of large experience in railway work, having superintended the construction of the systems of the Detroit Electric Railway Company, Niagara Falls, Toronto and a number of the Cleveland roads, covering a period of twelve years. The company have handsome offices in the new Majestic Building, in Detroit, and anticipate a very active business during the coming season.

J. G. WHITE & CO.

ANNOUNCEMENT is made in this issue of a new corporation. J. G. White & Co. has been organized under the laws of the State of New York, with a fully paid cash capital of $100,000. It succeeds to the business of the White-Crosby Company, of 29 Broadway, New York, and of Baltimore, formerly conducted by J. G. White & Co., in which firm the "company" was nominal.

When the White-Crosby Company was organized, it was planned that Mr. Oscar T. Crosby, who had severed his connection with the General Electric Company, in order to participate in the business of the new corporation, would devote a large portion of his time to the affairs of the company with which his name was associated. About the time the new company was organized, the very arduous work that Mr. Crosby had been doing for the General Electric Company and the Thomson-Houston Electric Company produced its natural effect, and consequently Mr. Crosby decided to take a recuperative trip to Europe. After returning to this country, Mr. Crosby decided to become more largely interested in local properties, and with this end in view, he and Mr. Charles A. Lieb acquired a controlling interest in one of the smaller street railways in Washington, D. C., and later organized a power and lighting company, which has grown into a large and flourishing institution. This and other local interests, such as those recently acquired in New York, have gradually and finally absorbed all of the time and attention of Mr. Crosby. In re-incorporating, under the laws of the State of New York, instead of under the laws of the State of West Virginia, it was finally, after mature deliberation, decided that as Mr. Crosby had voluntarily withdrawn from active participation in the business of the company, any chance of confusion as to its affairs would probably be lessened by adopting the name under which the business of the concern had been carried on prior to the date of the incorporation of the White-Crosby Co.

Mr. J. G. White, president of the old White-Crosby Company, and now of the J. G. White Company inclusive, was graduated at Pennsylvania State College in 1882, and having obtained a second degree (Ph. D.) at Cornell University, in 1885, taught physics in the University of Nebraska for two years. At the end of this time (1887) he formed the Western Engineering Company, with headquarters at Lincoln, Neb. In this enterprise he was joined by Mr. D. C. Jackson, now professor of electrical engineering at the University of Wisconsin, and Mr. Harris J. Ryan, now professor of electrical engineering at Cornell University. This company was sold to the United Edison Electric Manufacturing Company in the spring of 1890, Mr. White at the same time making a special agreement with the Edison Company as to contracts for the construction and equipment of electrical railways.

During the summer of the same year the Edison General Electric Company was formed, and Mr. White considered it expedient to decline the salaried position then offered him, and to begin business in New York on his own account. This was done in the fall of 1890, and the business then started was conducted continuously until the formation of the White-Crosby Company in May, 1894.

This firm, under the various titles above mentioned, has equipped a considerable portion of the electric railways of the country, having had contracts in Spokane,, Washington, Salt Lake City, Utah, Sherman, Texas, and in many cities and towns between these far-away points and the New England coast.

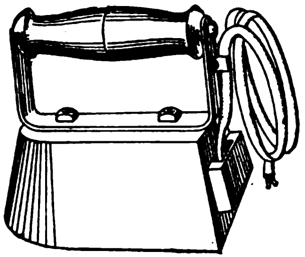
During the last five years, the contract work done in Baltimore alone has aggregated some three millions of dollars, and many other contracts have been carried to a successful completion. Amongst the more prominent of the recent contracts was the bulk contract for the Buffalo and Niagara Falls Electric Railway, and the contract for the transmission line complete, a few months ago, for the Cataract Construction Company, for carrying Niagara Falls power into the city of Buffalo.

The company has, at the present time, contracts for the complete construction and equipment of the street railways of Charleston, S. C., the changing of the "Blue Line" of the Baltimore City Passenger Railway Company from cable to trolley; the electrical engineering for a large transmission plant near Helena, Mont.; the building of extensions for the Norwalk (Conn.) Tramway Company, as well as other similar work.

As will be seen from the above, Mr. White was among the first in the electric railroad construction business, and the new corporation will have the benefit of his long and varied experience and of his well established reputation for first-class construction, careful and intelligent attention to details, and fair dealing. A continuation of his wonted success may confidently be expected.

TRADE NOTES & NOVELTIES

HATTERS' ELECTRIC IRON.

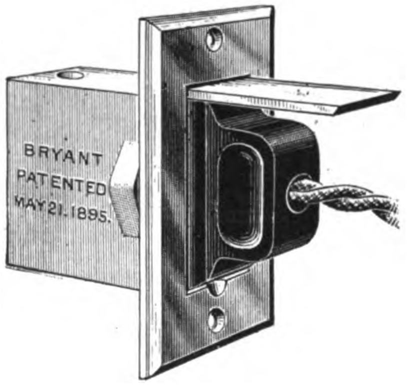


This is the conventional form of "Hatter's Iron" with polished sides and is used in many of the large retail establishments throughout the country, as well as by manufacturers. It is perfectly clean at all times, heats quicker than by other means, effectually doing away with leaky gas connections and other objectionable features incident to the older methods of heating. It is made for all lighting voltages by the American Electric Heating Corporation, of Boston.

THE CHAPMAN RECEPTACLE.

UNDER a recent arrangement made with Mr. F. A. Chapman, the patentee of the well-known Chapman receptacle, the Bryant Electric Company, of Bridgeport, Conn., are now the exclusive manufacturers of this excellent device.

This device has been on the market for a little over a year, and the fact that it has been indorsed by the underwriters and adopted by many of the leading engineers for use in some of the finest office buildings in the country is sufficient recommendation to the trade. Up to the present it has been made in one form only, as shown by the illustration, but it is the intention of the Bryant Company in the future to place several different designs on the market and make a number of improvements.



THE BRYANT-CHAPMAN RECEPTACLE.

THE EXCELSIOR ELECTRIC CO'S DYNAMOS AT THE WEST CHICAGO PARK.

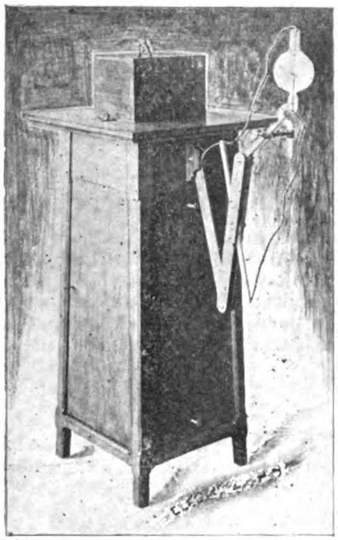
The Excelsior Electric Company, New York, are pushing hard for business in the Western States, as well as in other parts of the country, and have had good success in their efforts. One of the most important of the plants where their machines were installed within the past year was that of the new West Chicago Park's lighting station, where they placed seven of the largest arc dynamos that have ever been constructed, each having a normal capacity of 10 amperes at 7,500 volts. These machines are of their well-known arc lighting type and work in a remarkably easy manner, there being apparently very little difference in a machine running a few lights from any of the others which were carrying their full complement of 150 lights. These machines contain most valuable features, and make high tension work practical, and successful. For instance, if there should be an open circuit caused by any means, instead of the voltage suddenly rising and breaking down the cable, the machine simply flashes and spills over, and all danger of puncture is immediately avoided. These machines will run from one to one hundred and fifty lights with not more than 2 per cent. variation of current, thereby showing the perfection of the automatic regulator. The Excelsior apparatus has always had a good name, and stands higher than ever to-day.

FESSENDEN X-RAY MACHINES.

The latest development in the art of producing Röntgen rays is a remarkable machine which has just been placed upon the market by the Fessenden Manufacturing Company, of Pittsburg, Pa., operating under the patents of Prof. Reginald A. Fessenden.

The main points of this machine are simplicity both in design and operation. The Fessenden Company has proposed as its chief object, the production of a machine, which while giving the maximum spark results, which it is possible to obtain in the present state of the art, can be operated easily by any man of ordinary intelligence without knowledge of electricity or mechanics.

The induction coil is built perpendicularly and the resistance and condensers are so arranged that no adjustment of those appurtenances is necessary. The cost of operation of the machine is reduced to a minimum, a little oil and a few brass contact pieces, costing altogether only a few cents, being all that is necessary after a considerable run. The projecting rod on top of the machine is used as a starting device, it being only necessary to throw in the switch, push starting rod, and the machine at once starts up without any further attention or adjustment. The speed is regulated by an adjustable brush holder device. All of the starting and regulating device is so grouped that the operator may manipulate the same with one hand, while at the same time, holding the fluoroscope and taking views.



THE FESSENDEN X-RAY OUTFIT.

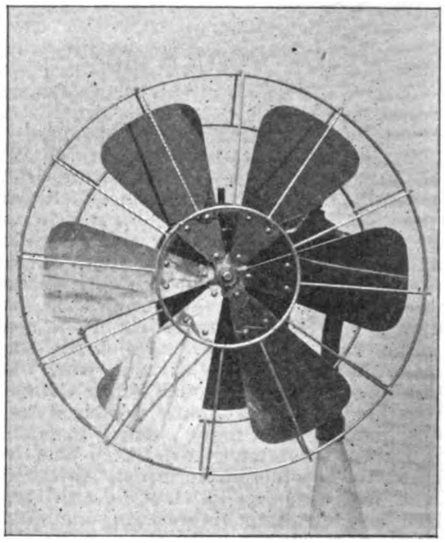
The framework of the machine is handsomely done in oak, mounted on castors, and altogether the apparatus is particularly suitable as an article of furniture in a doctor's office. These machines are made to operate from either direct or alternating current circuits.

THE SCHNEIDER WATER MOTOR FAN OUTFIT.

SUPPLY houses and central electric light stations are often called upon to furnish electric fans in territory which is inaccessible to electric light current. A great many central electric light stations are not running their plant during the day time, and during this time their customers desire the fans. To meet this condition, the Schneider Manufacturing Co., of 121 Euclid avenue, Cleveland, Ohio., have brought out the novel water motor fan outfit, illustrated in the accompanying engraving. This motor is designed on strictly scientific and mechanical principles by its inventor, Mr. G. P. Schneider, who has spent several years in bringing it to its present state of perfection.

The illustration shows a new six blade clover leaf fan which is very attractive and gracefully put together and perfectly balanced, so much so, that a slight breeze will turn the blades. Particular attention is called to the fan blade guard which is symmetrical in every way and makes the motor an ornament.

This motor is as easily installed as an electric fan, taking up very little space; the connection is made with any convenient hydrant or water pipe and is guaranteed not to leak. The motor is very economical in its consumption of water and can be operated on pressures ranging from 30 to 100 pounds pressure. The breeze produced by this fan is powerful, steady and noiseless, and the speed can be readily regulated.



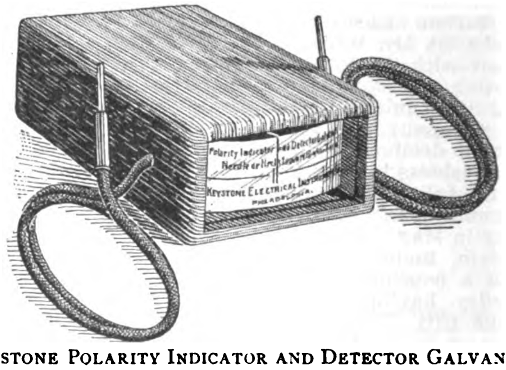
THE SCHNEIDER WATER MOTOR FAN OUTFIT.

We may add that Mr. R. C. Foster, formerly of the Brush Electric Co., of Cleveland, is president of the Schneider Co.

THE KEYSTONE POLARITY INDICATOR AND DETECTOR GALVANOMETER.

THE accompanying engraving represents a very handy little instrument built by the Keystone Electrical Instrument Co., of Philadelphia. The instrument is designed to indicate polarity of light and power mains on two and three-wire circuits, also the polarity of dynamos and batteries. It will indicate on circuits from 1 volt to 700 volts and a short-circuit cannot be made through it. It will be found very useful in setting arc lamps or motors.

The instrument is mounted in a neat polished walnut case, small enough to be conveniently carried in the pocket; its size is 3½ x 2½ x 1⅜ inches; weight, 4½ ounces, and is fitted with terminal leads. The pointer always deflects toward the positive terminal. It will further be found very useful as a pocket detector galvanometer and is applicable to all uses for which detector galvanometers are adapted. The workmanship and material are the best throughout and with careful treatment the instrument should last a lifetime. We may add that there is no liquid embodied in the polarity indicator.



Polarity Indicator and Detector
Keystone Electrical Instrument
Philadelphia
THE KEYSTONE POLARITY INDICATOR AND DETECTOR GALVANOMETER.

THE MICHIGAN PIPE WORKS IN FULL BLAST AGAIN.

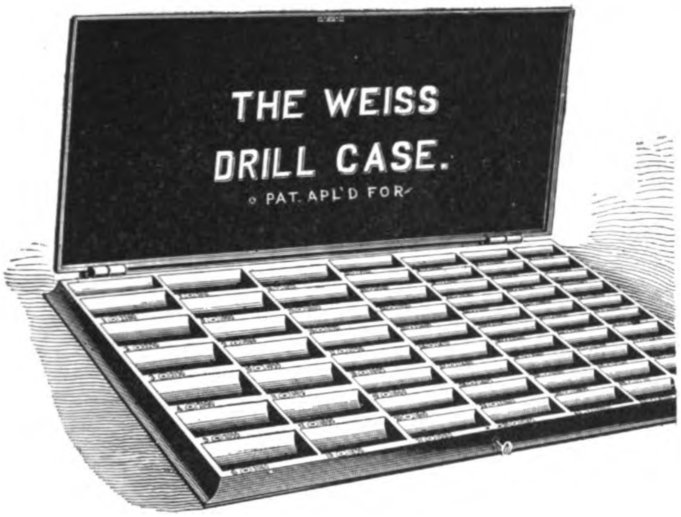
The extensive plant of the Michigan Pipe Company, of Bay City, Mich., which was destroyed by fire on the night of Dec.

8, 1896, has been rebuilt and started to work last week on a large order of pipe for a Western gold mine and on a large contract for treating cross arms for the American Bell Telephone Company. Their works have been completed in time to take care of this season's business for creosoted conduits for underground wire and have already made shipment of creosoted conduit and lumber for New England.

THE WEISS DRILL CASE.

ONE of the many petty annoyances of machine and repair shops is the time wasted in hunting up drills, and as time is money in a machine shop and as drills that cannot be found have to be replaced by new ones, a convenient means of keeping track of drills will be recognized as a paying investment. This has been provided for in the novel drill case brought out by Messrs. Weiss Bros., of 286-290 Graham street, Brooklyn, N. Y.; indeed the drill case, which is represented in the accompanying engraving, is the outcome of Messrs. Weiss Bro.'s sad experience in handling drills in their own machine shops.

As will be seen, the case consists of a cast iron hollow base having sixty round bottomed receptacles, No. 1 holding 16 and No. 60 about 200 drills. At the side of each compartment is a hardened and accurately ground drill gauge let into the case as a bushing, so that the workman can test the drill to see whether it is of the proper size. Beside the gauge is stamped the size of the drill in thousandths of an inch, so that a double check is thus afforded, and there is also given the exact size of drill to use for all standard taps.



THE WEISS DRILL CASE.

The cover of the case is provided with a spring hinge bar so that the cover cannot be slammed down, and so that it opens up by applying the tip of the finger.

The arrangement evidently shows at a glance every drill in the case and ought to be a valuable adjunct to every machine shop.

THE BERLIN IRON BRIDGE CO.'S WORK IN THE NARRAGANSETT ELECTRIC LIGHTING STATION, PROVIDENCE, R. I.

IN the description of the model composite station of the Narragansett Electric Lighting Company, at Providence, R. I., appearing in our issue of April 7,, we inadvertently omitted to mention the important work of the Berlin Iron Bridge Co., represented in the construction and working of the station.

The company's work consists of the roof, including the columns in the sectional view of the boiler room, on page 363, the roof work and columns shown in both illustrations on page 365, the roof work and traveling crane shown in the cross section at the top of page 368, and roof work and traveling crane in the arc dynamo room shown in the view at the bottom of page 368.

The Berlin Iron Bridge Company also furnished all the structural work of every kind in the building, including the roof covered with their patent anti-condensation corrugated iron covering. In fact, the original dynamo room in this plant was the first building ever covered with their patent anti-condensation corrugated iron roof covering.

A NOTABLE CONSOLIDATION.

Rumors appeared last week in the New York papers as to the proposed consolidation of the Sprague Electric Elevator and Interior Conduit & Insulation Cos., and the removal of the latter's factory plant to the Sprague works and grounds, at Bloomfield, N. J. The report is not officially confirmed, but is understood to have good foundation. Mr. J. P. Morgan is a large stockholder in both concerns, which between them do a very large and rapidly growing business under the energetic management of Messrs. E. H. Johnson and F. J. Sprague.

ADVERTISERS' HINTS

THE PURITAN ELECTRIC CO., New York and Boston, say that the Puritan enclosed arc lamp will bring business to central stations that otherwise could do no arc lighting.

THE ANCHOR ELECTRIC CO., 71 Federal street, Boston, ask if prices alone govern in deciding which switch to use, and offer to send descriptive catalogue of the Anchor switches whose good qualities are admitted by every one.

THE AMERICAN DISTRICT STEAM CO., Lockport, N. Y., will be glad to tell central station managers how they may increase their income. They have figures and examples to authenticate their claims.

THE NATIONAL CONDUIT AND CABLE CO., Times Building, New York, has been formed by the consolidation of the National Conduit Mfg. Co. and the National Underground Cable Co., and will carry on the business of both concerns. They have branch offices in Boston, Philadelphia and Chicago.

THE KEYSTONE ELECTRIC CO., Erie, Pa., claim twice as many electric elevators are operated by their special reversible motors and controllers as by any other make.

THE LECLANCHE BATTERY CO., New York, remind the public of the merits of the Gonda batteries and especially of the new "Vole Cell" which received the highest award at the World's Fair, Chicago.

THE MANHATTAN GENERAL CONSTRUCTION CO., New York, have sold over 12,000 enclosed arcs which are in successful operation nightly.

FISHER & CRAMPHORN, Congress and A streets, Boston, are the sole manufacturers of the Lyon brake handle. They also manufacture car brakes.

THE SAWYER-MAN ELECTRIC COMPANY, 125 Robinson street, Allegheny City, Pa., announce that the old, original Sawyer-Man lamp is still made and sold by them.

THE NEW YORK DYNAMO AND MOTOR CO., 257 Broadway, New York, are already behind on their orders for fans, which they are selling at $15.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, are ready with their stock of swinging-ball lightning arresters.

THE ELECTRIC STORAGE BATTERY CO., Philadelphia, have installed another large plant in Boston. It is described elsewhere in this issue.

NEW YORK NOTES.

THE ELECTRICAL CONTRACTORS' ASSOCIATION, of New York City, will hold their dinner on Wednesday evening, April 21, at the Hotel Flouret, Fifth avenue and Eighteenth street.

THE NEW YORK HEAT, LIGHT AND POWER COMPANY, holding very valuable franchises and established way back in the fifties, has been leased by Messrs. C. A. Lieb and O. T. Crosby, who will devote particular attention to the development of the company's light and power business which already covers a considerable territory in the lower part of the city. Pending a general remodeling of their plant the company is in the market for a good second-hand engine and 250-volt direct current generator of 200, 300 or 400-kilowatt capacity, either direct or belted, direct preferred, however.

OSTERBERG & SUTTON have removed from the Thames Building, New York, and are now in the Bowling Green Building, where they have gone into partnership as consulting electrical engineers and experts. One of their first pieces of work is the Bay Shore Electric Light Co.'s plant, which will have a capacity of about 100 horse-power.

AUTOMATIC ELECTRIC PUMP COMPANY has been formed at Brockton, Mass., with a capital stock of $1,000,000. It is to make pumps at Brockton, and will begin with a force of 100 men.

GREATER NEW YORK TELEGRAPHIC COMPANY has been formed in New York City by J. Fleischhauer, A. Lexow, R. J. Gersette, J. Fleischhauer, C. K. Lexow, J. Kienan, and J. Heffernan, with a capital stock of $5,000.

WESTERN NOTES

THOS. MUIR & SON, 31 Larned street West, Detroit, are pushing their aluminum reflectors and their automatic motor starter, and write: "We are greatly pleased with results from advertising in your paper."

MR. S. F. B. MORSE, who recently resigned the general Western agency of the Kerite wire products, has taken Mr. John D. Earle into partnership and will continue to do business at his old quarters, 1014-1015, the Marquette Building, Chicago. It is Mr. Morse's intention to remain in the same line of business in which he is so widely known, and he states that he is prepared to fill orders for a high class rubber-covered wire in connection with the other electrical goods for which he has the agencies, including the Pioneer enclosed arc lamp which is receiving considerable attention; the well-known goods of the Iron Clad Rheostat Company, O. K. junction boxes, and other thoroughly first class electrical specialties. On Mr. Morse's abilities as a hustler, and his sterling good qualities it is not necessary to dilate, as they are already well known. We merely wish him every success.

PRESIDENT F. H. FORD and his brother, A. H. Ford, of the Peoples' Electric Company, Madison, Wis., visited Chicago a few days ago, and called to the office of The Engineer. The Messrs. Ford state that things are brightening up considerably in their locality and that they are looking forward to good business from now on. As an evidence that business is rapidly improving in Madison, they state that their store is too small for their trade, and that they have to keep some of their goods some distance away, which is not altogether convenient. It is a matter of impossibility to get hold of a good large store now, as premises have been at quite a premium for some time past.

FOREST CITY ELECTRIC COMPANY, Cleveland, Ohio, report that their factory was visited by fire on April 12, and that several belting pulleys, etc., were destroyed by fire. Fortunately, no damage was done to the machinery itself, and by this time the company are busily turning out as usual their roll-drop commutator bars and other specialties.

THE FISCHER FOUNDRY & MACHINE COMPANY, of Pittsburg, Pa., builders of the "Fischer" single and four-valve engines, desire to contradict certain unfounded reports that have been in recent circulation, to the effect that the manufacture of engines has been discontinued by the company. On the contrary, it may be stated that additional features have been introduced, which, combined with the already known merits of the original makes of these engines, have especially adapted them for electric lighting and street railway purposes. An inspection of the company's shops in Pittsburg reveals a thriving and prosperous industry, and the business outlook for 1897 is flattering. Foster & Louis, general Western agents, have offices at 1000 and 1002 Fischer Building, Chicago, where the many friends of the Fischer engine, and, in fact, all visitors, will be cordially welcomed.

PHILADELPHIA NOTES

THE DICKSON MANUFACTURING COMPANY, of Scranton, Pa., have commenced the construction of a new boiler shop 130 feet wide and 225 feet long. This building will have a steel framework throughout. The sides will be covered with corrugated iron and the roof with composition roofing on plank. The main boiler shop is about 52 feet wide and 45 feet high. Thirty feet above the ground is a runway made of substantial steel girders which carry a 30-ton power traveling crane. At one end of the main shop is a riveting tower 25 feet by 50 feet, having a runway carrying a 20-ton crane 50 feet above the floor level. The crane in the riveting tower runs at right angles to the one in the main shop below. Adjoining the main shop is a punch room which is about 50 feet wide, extending the full length of the building. Attached to the roof trusses of this portion is a traveling crane of 5 tons capacity, which covers the whole floor surface. Adjoining the punch shop is a space for the flange fires and other furnaces, 25 feet wide and 225 feet long. All the main posts of the building are arranged so that jib cranes can be attached to them, and the trusses are arranged so that shafting and other machinery may be attached at convenient points. This building when completed will be without doubt the handiest and best equipped shop of its kind in the country. The steel work was designed and will be furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

MR. H. B. COX, of Cox thermo-electric generator fame, has sailed from England for this country and is expected during the present week.

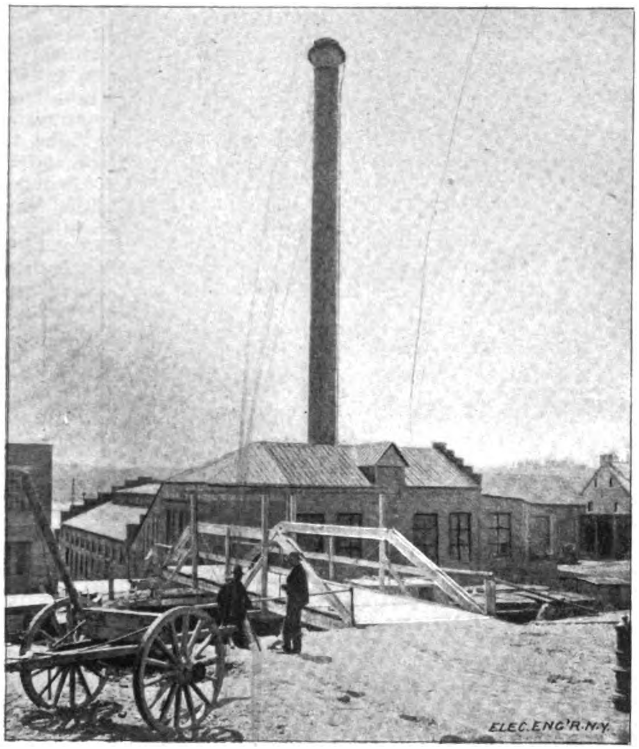
Vol. XXIII. APRIL 28, 1897. No. 469.

ELECTRIC LIGHTING

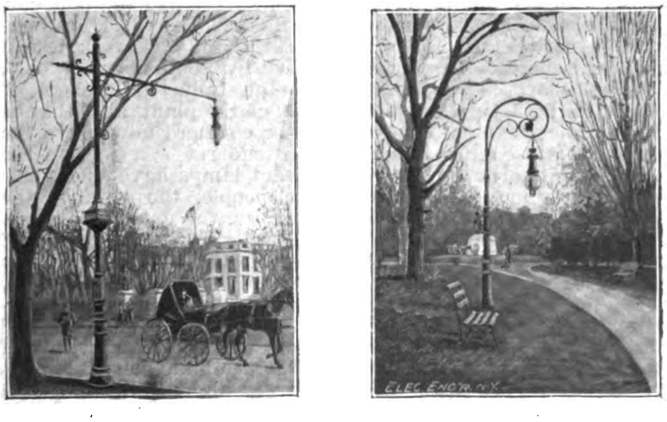
THE STATION OF THE POTOMAC LIGHT AND POWER COMPANY, GEORGETOWN, D. C.

BY N. MONROE HOPKINS.

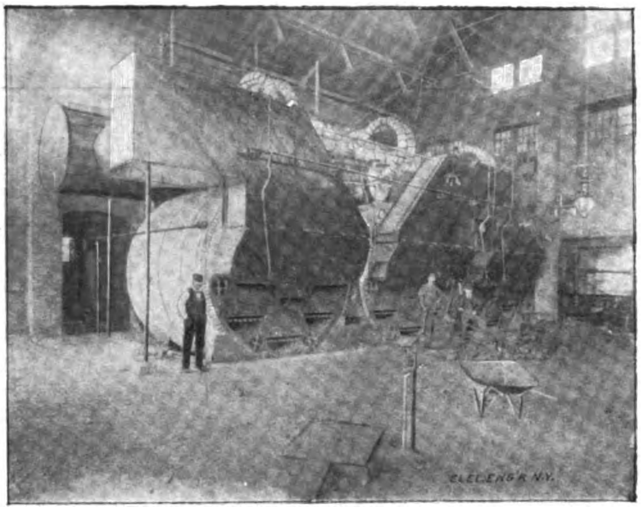
SITUATED on the river front at the foot of Thirty-third street, Georgetown, D. C., is the power station of the Potomac Lighting Company, operated under the personal control and management of Mr. Oscar T. Crosby and Mr. C. A. Lieb. An old building, at one time used for foundry purposes, now covers a modern electric plant and answers admirably for the purpose, although located as it is, on the incline of one of the steepest hills in Georgetown. The engines and dynamos occupy the elevated portion of the building and the battery of boilers the lower portion near the river. Water is taken from the canal that runs past the station at the top of the hill, and passes by gravity through a filtering plant having a capacity of 200,000 gallons in 24 hours. The water as it leaves the filters is taken up by Worthington pumps and fed to the boiler battery which consists of three 600-horse-power Scotch fire tube boilers of Cramp manufacture. Steam is furnished at 125 pounds initial pressure through asbestos covered pipes; the system of steam distribution being entirely in duplicate.



Power House, Potomac Light and Power Co.

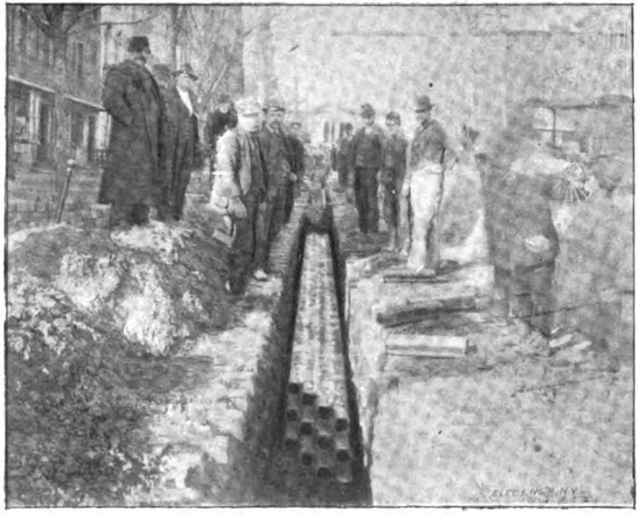


Electric Light Poles in Public Parks, Potomac Light and Power Co., Washington, D. C.



Boiler Room, Potomac Light and Power Co.

By ascending several steep flights of stairs which climb the hill, one reaches the engine room and is immediately impressed with the beauty of the splendid modern engines and generators. The main engines are two in number, of 1,200 horse power each of the cross-compound condensing type, having cylinders 48 x 18 inches, with 48-inch stroke. They are of the American Wheelock type, equipped with the Hill automatic cut-off valve gear, and built by the Cramp Ship and Engine Building Company, of Philadelphia. The generators are directly connected, being mounted between the high and low pressure cylinders the armatures revolving with the engines at 90 r. p. m. Each generator has ten poles and is of General Electric manufacture, with a capacity of 500 kilowatts and delivering the current at 550 volts.



ELEC. ENG'R. N.Y.

Laying Underground Conduits, Potomac Light and Power Co.

Adjoining the main engine room to the left on ascending the steps, is another, smaller in size, and equipped for furnishing alternating currents. Two Stanley alternators of 120-kilowatt capacity furnish power at 2,000 volts when running at 800 revolutions per minute. One generator is driven by a Crocker-Wheeler four-pole motor of 125 horse power wound for a 550-volt supply, the second is driven by an Ideal horizontal steam engine built by the Harrisburg Foundry and Machine Company, which is also run on a condenser, and is of 125 horse power.

The main switchboard is of black slate mounting General Electric and Weston instruments and is situated in the main engine room.

At present the station supplies Washington with about 200 arc lights distributed through the numerous parks and squares. The system of distribution is entirely by conduits of vitrified material laid in cement and broken stone with approved manholes at frequent intervals. In the engraving can be seen the type of arc light poles in use designed by Mr. C. A. Lieb. The arcs in the parks are suspended only eight feet above the ground, and give a steady, powerful light.

In addition to the current for the arc lights, the station also furnishes power for five electric railroads, as follows: Georgetown and Tenallytown, operating at this season about six cars; Great Falls Railroad, with four cars; Fort Meyer and Arlington Railroad, with two cars; Falls Church Railroad, with two cars, and the Glen Echo Railroad, with two cars.

Engine and Dynamo Room, Potomac Light and Power Co., Washington, D. C.

MUNICIPAL OWNERSHIP AT ALAMEDA, CAL.

We are indebted to a correspondent for the following "Object Lesson in Municipal Ownership," which lesson comes from the operation, at Alameda, Cal., of a municipal electric lighting plant: "The present city officials of the city of Alameda acknowledge the cost of each electric street lamp, per annum, to be $90; hours of lighting, 1,300; cost per hour per lamp 6.8 cents. The city of Oakland, Cal., under existing contract, pays for each lamp per annum, $151.34; hours of lighting, 3,600; cost per hour per lamp, 4.2 cents. Loss by municipal ownership on each lamp per annum, $33.80—assuming $90 to be correct. Loss of taxation on plant should also be added. Actual cost to taxpayers in Alameda has been, per lamp per annum, about $135; cost per hour, 10.3 cents; loss per annum, on 100 arc lamps, $7,930."—Am. Gas Light Journal.

CO-OPERATIVE ELECTRIC LIGHTING IN THE VILLAGE OF BORSBEKE, BELGIUM.

BY PROF. H. SCHOENTJES (University of Ghent).

Borskeke is a village or commune in Eastern Flanders, situated in a rural district on the line of the railroad between Brussels and Courtrai. It has a population of 1,150 souls and has a co-operative dairy or milkery affiliated with the agricultural committee of Herzele, under the supervision of M. Versnick. At the beginning of 1896, the growth of the dairy having made necessary a steam engine, the administration resolved to buy one of larger power than was actually required and to use the surplus for public and private lighting. The installation having been decided on, an extension of the co-operative plan was decided on to handle it, and a new company or society was formed, of which I have had the honor of being selected as the consulting engineer. The work was entrusted to Bouckert & Co., of Brussels, and the work begun about the middle of July was finished by September 20, 1896. After a short course of study at the Industrial School of Ghent, M. De Lange became director of the plant, and, thanks to the same means of study, a former cowherd now plays the part of steam engineer and dynamo tender.

Since September 20, the incandescent lamps have shed their soft beams in the houses of the people, the church, the thatched cottages, the barns and stables, the dairy, the wine-shops and the railway station of Terhaegen. The evening of the inauguration two arc lamps were installed temporarily for the banquet in the schoolhouse. It is true that the bare poles, lines of wire, and glaring white insulators do not harmonize with the picturesque aspect of the green pastures and the great poplars of this rural region, but the farming folk of Borsbeke are in general indifferent to aesthetic considerations while they rejoice in the fact that every night 40 incandescent lamps, like shining beacons, indicate the silent streets and brighten up roadways hitherto plunged in deepest darkness.

The expenses of the electrical installation reached about 19,-500 francs ($3,900), which comprised half the cost of the steam engine, the boiler plant and the smokestack. The co-operating parties interested in the plant subscribed each for one share of 100 francs per lamp of 16 candle power and pay annually 10 francs for the maintenance of each lamp. They have also the privileges of taking up the share of stock in 12 payments of 9 francs per annum; in which case they pay annually 19 francs per lamp. The amount for the stock not taken up was advanced by Burgomaster De Vuyst and his son Agricultural Inspector De Vuyst, at a rate of 3 per cent. interest. Each co-operator pays half the expense of his lamp renewals. The commune of Borsbeke is stockholder like individuals, and takes forty lamps for public lighting. Its stock cost it 4,000 francs, and it pays 300 francs per year for service instead of 400 francs, a reduction being made in this way to all large users. It also gets a reduction for lamps not burning often. The railway station at Terhaegen and the church take six and seven lamps respectively; but as the railroad company and the church cannot join the co-operative society each pays a definite amount fixed on the above ratios.

The steam engine was made of Lebrun, of Nimy, and is of 23 horse power, non-condensing, although a condenser is to be added. The fire tube boiler has a heating surface of 30 square meters, and was furnished by Brouhon & Co., of Liege. The dynamo is a two-pole, shunt-wound Schuckert, of 10 kilowatt capacity, and it is supplemented by a battery of 65 Julien accumulators, of a capacity of 15 amperes for 10 hours. The switchboard is of Schuckert make and permits the following combinations: Direct supply to the system by the dynamo; charging batteries; supply to both the batteries and the system at once; lighting by the batteries alone. The 40 lamps on the public highways are protected by globes and have enameled shades. They are carried on swan's-neck metal poles, which also support the conductors. The circuits run out in four directions, and the furthest lamp is 800 metres from the plant. The installation is of the two wire type and current is furnished at the regular 110 volts. The public and private lighting circuits are separate, and the network is supplied by three feeders. The centers of distribution are the public lamp posts. Villagers living in the vicinity of one of these posts throw on the current for that section at a given hour by closing the switch, which is affixed to the post in an oaken box.

The regulation of the system is as simple as possible. At full load the voltmeter of the dynamo shows 124 volts, and all the attendant has to do is to manipulate the rheostat in the field to keep the indicator needle steady between its limits. Two colored lamps and a bell are in the circuit in the dairy building, and guided by these the attendant dispenses with all other means of control. The system is figured out for 150 lamps of 16 candle power. It started with 125; at the time of writing it has reached 165, and in the near future it will touch 200. Of course there is never a time at which all these lamps burn together.

In the morning, the steam engine runs the dynamo for charging the accumulators and operates the dairy. In the evening, the engine and dynamo are given up to the public and private lighting. When the street lights are shut down, the system is switched over upon the Julien batteries and all the rest of the plant is stopped. The engine and boiler plant are freely used by the two co-operative societies together, at times, under very favorable conditions. In summer, when the lighting is at its minimum, the power necessary for the dairy is at its maximum. On the contrary, in winter, the dairy does but little work and the lighting is in full demand. The society now proposes to extend its operations, and will endeavor to furnish electric power to the various farms for different classes of agricultural machinery. A third co-operative society is being formed, for an agricultural distillery, and this is also to derive its power from the dairy plant. One of the cultivators of the village has been sent to the Industrial School at Ghent to learn the methods of operation, so that he can take charge of the new plant; just as was done in the case of the electrical installation.

Such in brief is the history of the electric lighting of the village of Borsbeke. The modest little commune in creating its plants has taken an initiative which ought to be fertile of imitation, and has the credit of making the first application of the principle of co-operation on this basis, to a public service.

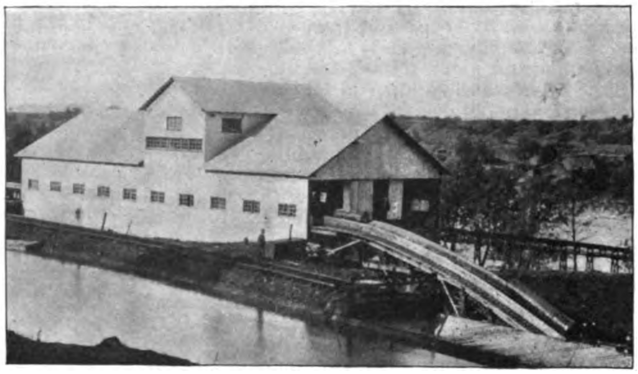
NEW YORK CITY.—A bill has been introduced in the State Senate by T. D. Sullivan, to confer very considerable powers on the New York Electric Light Company (R. B. Ayres, T. B. Robertson and J. B. Hawes), to furnish electricity and gas and to put down a subway system anywhere they choose. It is exempted from existing restrictions in all respects. The capital stock is $500,000. It is hardly conceivable that such a bill can go through the Legislature.

THE NEW ORLEANS DRAINAGE BOARD is considering the plan of the operation of its pumping stations by electric motors furnished with current from a central power plant.

POWER TRANSMISSION

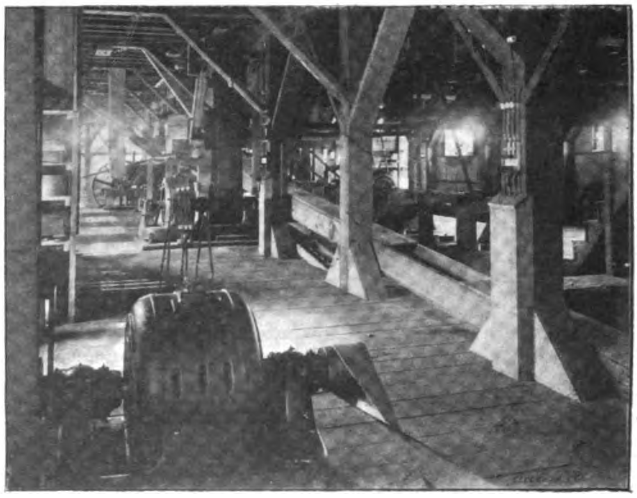
ELECTRIC SAW MILL AT FOLSOM, CAL.

THE electric power transmission from Folsom to Sacramento, Cal., has been described fully in our pages and is deservedly looked upon as one of the most successful undertakings of this kind thus far carried out. But in utilizing the American River, the source of power, the projectors of this enterprise also had in view the application of power close to its source of generation and consisting of the driving of saw mills to saw the timber of the forests situated above Placerville, between the South and Middle Forks of the American River.



ELECTRIC SAW MILL OF THE AMERICAN RIVER L. & L. CO., FOLSOM, CAL.

The American River Land and Lumber Company own about 20,000 acres of this forest land. Into this tract they have built a railroad nine or ten miles long. Powerful donkey engines are used to haul the logs to this railroad—in some instances a mile distant—by a wire cable. They are then loaded on cars. At the lower terminus of the railroad, from a point 1,300 feet above the level of the South Fork, a chute 3,000 feet long has been constructed and the logs are shot down it into the river, from the terminus of the company's railroad. They bring up without injury in a deep pool about a mile long made by the erection of a dam below. From this dam to the booms above Folsom is about forty miles, and the logs are during the spring freshets caused by the melting snow readily and very cheaply driven to the booms, arriving there by the middle or last of June.



INTERIOR OF ELECTRIC SAW MILL, FOLSOM, CAL.

The big electric saw mill built by the company at Folsom, the first saw mill in the world to be run entirely by directly transmitted electric power, started up Dec. 4, 1896.

For the saw mill a switchboard panel has been placed in the electric power house of the Sacramento Electric, Gas and Railway Company at Folsom, and the power is transmitted direct to the mill, 600 feet away, through three No. 1 B. and S. gauge wires, and it is calculated that this direct application of power by the means of electricity, doing away with much belting, shafting and other machinery, will save fifty horse power.

The motors are all on the lower floor except one, which supplies the filing room in the upper story. The motors are all of the induction type. First in size and importance is the 75-horse-power motor that runs the big band saw by direct power. It has a speed of 600 revolutions per minute. This and the next largest motor have a voltage of 720. Next comes the 50-horse-power motor that runs the edger, with 700 revolutions per minute. These take power directly from generators at the power house.

There are three 30-horse-power motors, with 900 revolutions per minute and 200 volts. One of these runs the log roll and the sawdust and slab conveyors. The second runs the log carriage and friction plugs to reverse it. The third runs the trimmer and live rolls and the sawdust conveyor. In the filing room on the floor above is a 5-horse-power motor that runs the saw filer and some minor machinery.

The filing room contains a machine that is simple, but is perfection. The big saw is placed in an elliptical frame, teeth upward, around the machine, which is run by the 5-horse-power motor. When the machine is started, two "tenders," or ratchets, one on each side of the machine, catch each tooth in succession and move the saw the length of a tooth at each jerk. An emery wheel rises along the back of the tooth, grinding and pointing that side of it and then dropping between it and the next tooth, grinds the front of it. The saw is moved steadily around until it is ground to the satisfaction of the operator. The transformers in the mill transform the voltage for the three 30-horse-power motors from the generator down to 200 volts, and the 150 incandescent lights are also taken from the transformers.

The mill is entirely lighted by electricity. All the motors are of the induction type built by the General Electric Company, who also furnished the generators and electric machinery in the power house of the S. E. G. and Ry. Co.

ROENTGEN RAYS

THE X-RAY ARC.

BY R. W. WOOD.

I NOTE in The Electrical Engineer of April 14 a short description of a new method of producing the X-rays by an arc discharge, discovered by Mr. Tesla. For the past three months I have been using this form of discharge for the production of the rays for diffraction work, and on March 31, several days prior to Mr. Tesla's announcement, sent a very brief note to "Science" on the subject, which appeared in the April 9 issue of that journal. A more detailed account of the work had already been sent to Wiedemann's Annalen.

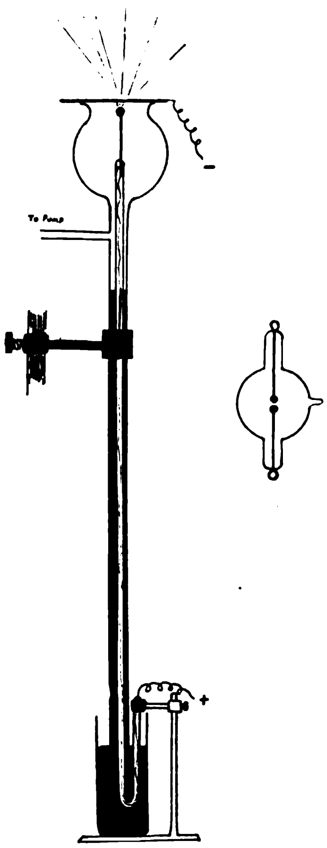
Curiously enough, one form of tube which I have used is almost identical with the one described by Mr. Tesla, and illustrated in the Engineer. The discharge-bulb is a so-called "thistle tube," with a very thin plate of aluminum, which serves as a cathode, cemented over the top, Fig. 1. The anode is a small ball of platinum close to the plate, on which the arc plays, and from which the X-rays emanate, passing through the aluminum plate into the air.

The platinum ball is carried on the upper end of a tube bent into a U at the bottom, and passing up through a mercury barometer column into the bulb, the arrangement being that devised by the writer for determining the temperature curves in the stratified discharge in Geissler tubes, by means of a sliding bolometer[1].

By means of this device the distance between the ball and plate can be nicely adjusted, and I have had no difficulty in producing a steady discharge of the arc, which Mr. Tesla says is maintained with considerable difficulty.

A form of tube shown full size in Fig. 2 has been found more serviceable in many respects, and has been used rather more than the other. In general it has been made with one electrode moveable like the first, but I find that it can be made to work with fixed electrodes, and when removed from the pump, as shown in the figure. Here the arc passes between two small platinum balls. The anode gives off X-rays and is eaten away into a crater, while the cathode has a brilliant deposit of platinum built up on it.

Mr. Tesla does not state the degree of exhaustion of his tube or with what sort of a current he excites it, but presumably his method is in general identical with mine. The vacuum can be somewhat lower than that usually found in Crookes tubes and a spark gap in the external circuit seems to be necessary for the production of the arc. I have used for the most part the current of a 12-plate Wimshurst machine, since for the work on which I am engaged it is better to have only one ball radiate. With the alternating discharge from a high frequency coil both balls would radiate, but as they are but one-twentieth of an inch apart this would be no disadvantage.



ELEC.ENG'R.N.Y.

FIGS. 1 AND 2.—WOOD X-RAY ARC APPARATUS.

It seems quite likely that tubes made on this principle can be constructed sufficiently well insulated and small enough, to be introduced into the cavities of the body. With the one shown in Fig. 2, which is less than an inch in diameter, I have seen the bones of the forearm quite distinctly.

The work spoken of in this note has been done during the past winter, in the physical laboratory of the Massachusetts Institute of Technology, through the courtesy of Prof. Cross, who placed every facility at my disposal.

X-RAYS IN AN ACCIDENT CASE.

A special dispatch from Wichita, Kan., says: Lucien I. Blake, Professor of Electricity in the University of Kansas, arrived in the city to take a Röntgen shadowgraph of the wrist of Pete Noel, who has brought suit in the District Court against the Atchison, Topeka and Santa Fé Railroad for $10,000, claiming that the company's physician damaged him to that extent by bunglingly setting his fractured wrist. The shadowgraph will be introduced in evidence, plaintiff and defendants having agreed to accept it as final evidence.

MR. M. H. CRUMP, B. M., Cadet Adjutant, Kentucky Military Institute, Lyndon, Ky., writes us: "Your paper is regularly received and read with great interest. It grows more and more interesting with each number. The articles on the storage battery are of great use to me in my classes."

TELEPHONY AND TELEGRAPHY

THE VIADUCT TELEPHONES, FACTORY AND PERSONNEL.

THE Viaduct Manufacturing Company is keeping abreast of the times by issuing new and improved apparatus for telephone purposes, as will be seen by cuts on this page. We also show a view of its extensive works at the Relay Station, B. & O. R. R., between Baltimore and Washington. These works are directly under the Great Viaduct from which it derives its name "Viaduct." This is the first stone bridge constructed in the United States for railroad purposes. It was commenced in 1833 and finished in 1836 and serves for the passage of trains from Baltimore to the capital. It is a remarkable bridge, or viaduct, having stood for over sixty years. There never has been an accident of any kind upon it, the repairs are almost insignificant, and with from 70 to 100 trains a day passing over it. It is a matter of fact that the B. & O. R. R. were compelled to make this curve and erect this viaduct where it is located to accommodate the former owner of the viaduct property. He insisted upon this location in order to accommodate the mill which he owned and ran by water power. Portions of the same mill are now used by the Viaduct Company in carrying on their extensive electrical factory. The Viaduct Manufacturing Company purchased this property in 1880; it has been twice burned to the ground, the last time in 1894, when there was nothing left to tell the tale. The present buildings were quickly constructed and filled with the most modern machinery for the purposes required.

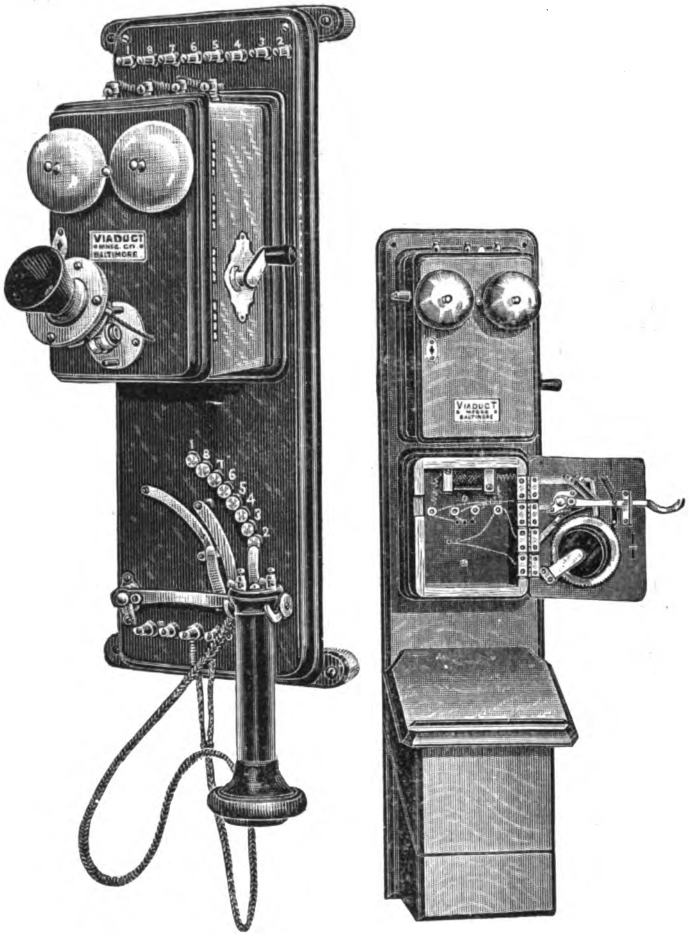
ELEC.ENG'R.N.Y.

A. G. DAVIS.

VIADUCT MFG. CO.'S FACTORY, RELAY STATION, BALTIMORE.

Everything connected with a telephone outfit is manufactured in these buildings. It is said to be the most extensive establishment in this country of its kind, with the exception of the American Bell Telephone Company's factories of the Western Electric Company, in Chicago and New York. Its capacity is almost unlimited; it owns the water power and 25 acres of ground with all the buildings contained thereon, some twelve in number.

Mr. A. G. Davis, the president and principal owner of this company, is an "old-time telegrapher," having learned the art under his cousin, Prof. S. F. B. Morse, inventor of the telegraph, in 1849, and he had charge of the Poughkeepsie telegraph office at that time. In 1853 he went to Canada and had charge of the Grand Trunk Railway telegraph system until the war broke out in 1861, when he moved to New York, and thence to Baltimore, and was superintendent of the B. & O. and Western Union telegraph system for many years.



INTERIOR, OR WAREHOUSE TELEPHONE SET AND DEVICE TO REVOLVE TRANSMITTER.

He originated the American District Telegraph Company of Baltimore and other places; also the Gold and Stock Ticker system in Baltimore; and the Maryland Telephone Company, now the Chesapeake and Potomac. He was the original licensee of the American Bell Telephone Company for the State of Maryland, and his factory was also a licensed manufacturer for that company during the early stages of the telephone.

The telephonic apparatus here shown is new and is typical of the variety and ingenuity of the products of Mr. Davis. The "Interior" or warehouse telephone set is a very compact arrangement and provides for a number of lines centering conveniently on the backboard. The other cut illustrates the ingenious arrangement to prevent the "packing" of the loose carbon which is so serious a defect in transmitters of the Hunning type. In this Davis transmitter, every use of the telephone—every removal and replacement of it on the hook—revolves a step the carbon box or receptacle, thus giving it a gentle shake up and new adjustment. In this manner, the carbon never stays long enough in one position to pack, and the sensitiveness of the apparatus in speech transmission is enormously increased.

AUTOBIOGRAPHY OF THE OLDEST WOMAN TELEGRAPHER IN THE WORLD.

BY MRS. JULIA ABRAMS.

IN response to the inquiries of The Electrical Engineer and the kindly interest manifested in myself, and my early career as a woman telegrapher, I will endeavor to give the desired information, hoping the history may be of interest to the telegraphers of to-day, who know little of the varied duties and difficulties that the early workers had to endure and overcome, especially by women who were in those days considered outside the lines of womanly work. My husband, Leonard Abrams, was one of the earliest operators in the profession. He was an operator when I was married to him, and I learned telegraphy in his office, the Atlantic, Lake and Mississippi line, at Massillon, O., during the winter of 1849 and 1850. The spring of 1850 Mr. Abrams was called to Cleveland, O., to relieve an operator in that office for two or three weeks, and I was placed in charge of Massillon office. I well remember the consternation of a commission merchant who desired to send a telegram, and found Mr. Abrams absent. He would hardly be convinced that his message could be handled by a woman, but decided to risk it if I would permit him to come inside the office to oversee the sending. Pittsburg answered promptly, I sent the message, and assured the doubting man that it was gone. Fortunately a quick reply was received and the customer was convinced that a woman could do what a short time before he had supposed an impossibility for anybody.

Soon after, Mr. Abrams was called to Cleveland for a permanent position, and I was again left in Massillon office until relief could be found. Meanwhile the business men were so well pleased with my services that they wished arrangements should be made for me to remain in charge. In 1856, Mr. Abrams accepted a position with the Michigan Central Railway, at Niles, Mich., in connection with another man operator. In 1857 the other operator was transferred, and I was appointed to fill the vacancy, working with my husband in that office until the fall of 1865, when we both retired from the business, to spend our declining years in Niles, Mich., where Mr. Abrams died in 1889.

During the years of our service Niles had no city telegraph offices, as now, but all commercial business was handled by us in connection with our railroad work. During the War of the Rebellion the business was heavy. We also handled the ticket office, which was in our office, as a part of our railroad duty. We taught quite a number of pupils, who were sent out into the service, and so far as known to us not one proved a failure in the profession. Stephen Robinson, for some years manager of the Board of Trade office, Chicago, and now a prosperous man on "the Open Board," was one of our students; also his brother, Byron Robinson, for some years, and at present, in the telegraph service in the Union Pacific Railway; Millard Bullard, who was superintendent of telegraph for the Missouri Pacific Railway, some years, and until his death, was another of our "boys"; Elbe Howe, agent and operator for the M. C. R. R., Dearborn, Mich., the past thirty years, and with the M. C. R. R. about thirty-five years, was also taught by us. We also had one young woman student, Rebecca S. Bracken, who has been nearly thirty-two years in continuous service with the Michigan Central, all the years (except her first office six months in Buchanan, Mich.), in Niles, Mich., where she is yet manager of the M. C. R. R. office, which has grown into an important division point, with many wires and heavy work. As a pioneer woman in telegraphy, I was called to endure many hardships, and overcome obstacles, but by the help and under the practice of my good husband, I was able to meet all in a true womanly way, that won the respect of the public, and I have now an honored place in society. A volume would hardly contain all the vicissitudes of my experience, yet looking back from my now eightieth year, I find nothing to regret, but much to remember with pleasure, while I wait the last "call" that I must answer for promotion to be with the husband who was summoned before me.

Niles, Mich., April 3, 1897.

TELEPHONES FOR KANSAS CITY SCHOOLS.

The Kansas City Board of Education has made a contract with the Missouri and Kansas Telephone Company for telephone service in all the public schools. A switchboard will be placed in the secretary's office and private lines run to all the school buildings. This service was decided upon by the board for sake of convenience and for use in case of fire in any of the school buildings, or to give the alarm to the teachers if a heavy storm be approaching. The city has had some lively experiences with cyclones and parents like to get their children home out of the way.

VENEZUELA TELEGRAPH MONOPOLY.

Jacob Schwed, who represents a syndicate organized by the banking firm of Henry Clews & Co., has returned from Venezuela. It was announced at the office of the firm that he has secured from the government a concession, already noted in The Electrical Engineer, which gives to the syndicate a complete monopoly of telegraph, cable and telephone lines in Venezuela. The concession is for 30 years, and the syndicate is to pay the government of Venezuela one hundred and fifty thousand dollars a year. The syndicate will take over the existing lines, which are owned by the government, and it may begin operations under the concession any time within the next six months. At the end of thirty years the lines will revert to the government on payment by the latter to the syndicate of their appraised value.

ELECTRIC TRANSPORTATION

AMERICAN STREET RAILWAY FINANCE.—III.

BY E. E. HIGGINS.

It is easy to see that the people of a city will, as a rule, be anxious for more facilities, and they will naturally further any efforts made by outside people to come in and build more street railways. The common councils were naturally anxious to have the same things done, and knowing that the people were behind them, it was quite easy to obtain franchises by the old or new companies. The consequence was a great over-building of street railway lines in many of the cities, not only of building for the future, which is legitimate for a long time investment; not only running into the suburbs and generally into places where traffic can be created in time; but the actual parallelling of existing roads where the service was not necessary on a broad view of the traffic conditions in the given city, and consequently the necessity of keeping up the mileage and operating cars over it, and all the consequent evils of over-building.

That fact is particularly noticeable I think in the West. Partly because of this over-building, and partly because roads were put into small cities, we find such significant features in the statistics which I read a few moments ago. For example, while the Eastern States contain sixty-four per cent. of the large cities they contain only forty-four per cent. of the mileage. The Western States, however, contain six per cent. of the cities above fifteen thousand inhabitants, and sixteen per cent. of the mileage; in other words, a very much larger proportion of mileage to the cities served than is found in the East. The Central States have nineteen per cent. of the cities, and thirty-two per cent. of the mileage. The South has eleven per cent. of the cities and eight per cent. of the mileage. There is not so much over-building in that section, it would appear from the figures, as there is in the West, but there are one or two cities of the South which have suffered from considerable over-building. It may be said that while the Western cities contain six per cent. of the cities, they have ten per cent. of the total capitalization of the country, while the Eastern States have sixty-four per cent. of the cities, and fifty-seven per cent. of the capitalization.

Now over-building is a pretty bad thing for street railroads. It means not only the maintenance of track, but it means excessive car service. Suppose you have two parallel streets in a rather small city on which you have railroads; you cannot give a five-minute service on both streets and live. The usual way of solving the problem is to give a ten-minute service on each street which practically gives a five-minute service on both streets the cars being started every five minutes, considering the two lines as one. This, of course, implies a knowledge of schedules on the part of the public, and the minute you begin to talk about schedules on street railways, people begin to walk. They do not want to bother with schedules. If they know they can get a car by waiting five minutes they will do so; otherwise they will probably walk so far that when the car overtakes them they will not consider it worth while to ride the rest of the distance they intend going. This principle can be applied in many ways, and nothing more need be said upon this point.

When we come to transfers, we run across another series of difficulties all having at their root the inherent disposition of the American people to cheat a corporation. I had a transfer problem presented to me the other day which was very interesting. The business center of the town was so situated that the lines converged at that point, all coming from opposite directions. Ninety per cent. of the traffic of that city daily comes in from the outlying sections to the business center and goes back again; sometimes it may be ninety-five per cent. In this case the street railway company estimates it as ninety per cent. at least.

Now if that company grants transfers they are going to have difficulty. Many people will come in on a certain line and take a transfer whether they require it or not, and will either dispose of the transfer to some storekeeper, or make arrangements with some one to exchange them, and they will spend fifteen minutes in doing it each day so that the tickets may be used. Time is no object when it comes to saving five cents and a street railway company is the loser. Perhaps ten per cent. of these people want to go on these lines running out from the center of the city. If you have a transfer agent at this point, it means a great expense and many tickets will be given away to those who are not entitled to them. Many men make a daily practice of getting close to a car and when it stops they slip in with the crowd and get a transfer ticket. A gentleman who was talking with me about this particular city said that he made an investigation to see what the transfer system in New York City amounted to, and he went to a certain point where they had an agent in the street and he tried that little trick of going up with the crowd eight times in succession and he got his transfer eight times and was not detected in doing so.

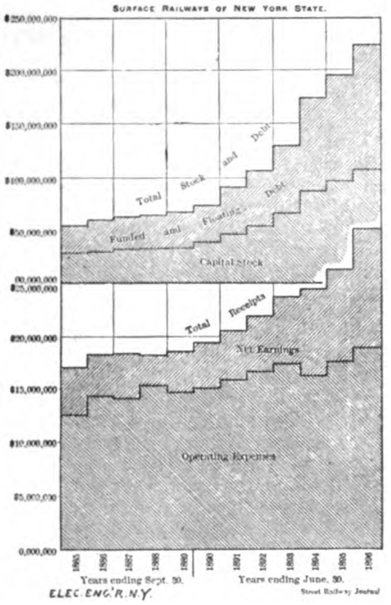


FIG. 1.

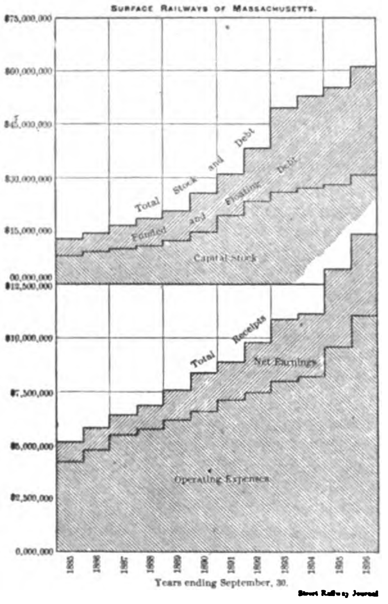

FIG. 2.

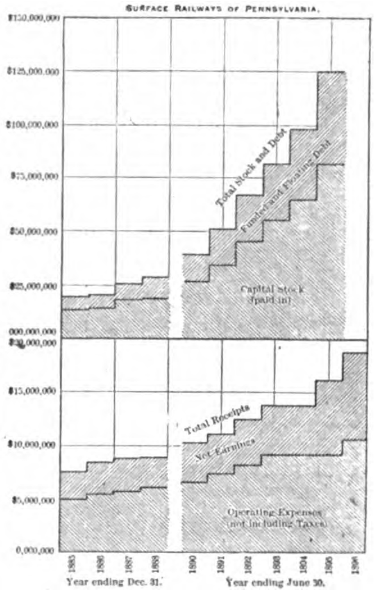

FIG. 3.

It seems rather a hard thing for a city to compel a company in a case like that we are considering to put a transfer system on for the benefit of ten per cent. of the people who ride on the cars. It necessarily means in a case like that, where the number who want to transfer is so small, a large reduction in income because of the loss and misused ticket; it means that a force has to be established to take care of transfers and check them up, or the conductors will dispose of them in saloons. These difficulties are hard to explain to the residents of a city through the press, and the press itself is oftentimes misled about them. It is a matter of conditions. Citizens of certain cities see that transfers are being granted in other cities. A few men may happen to want transfers to go to some point which cannot be reached by a single fare, and they think it is a shame that they do not get them. Sometimes it is a good thing for the company and for the citizens alike that transfers shall be issued. Frequently transfer systems are introduced with the idea of increasing the revenue, but it is a question of conditions, and conditions are so different in various cities that it is by no means a truism that all the cities ought to have the transfer system.

There is one other feature of the traffic question which should be mentioned. In the thickly settled cities of the East, car speeds are small, necessarily small, because it is difficult to thread one's way through and among the cars and drays, etc., in the principal streets. In the West there is not nearly so much of that obstruction, and car speeds are very much greater, and the car miles per day, or the mileage per day per car is much greater. That has been the financial salvation of many of the Western roads, their ability to get more service out of their equipment and out of their car force, conductors and motormen, than can be done in the East. We find frequently that the Western roads operate at eight or ten cents a car mile, whereas in the East fifteen to twenty-five cents is the general run of expenses. It makes a great deal of difference whether you divide your expenses by 150 or 175 miles per car per day, or whether you divide them by 80 or 90 miles per car per day.

I pass from these general considerations to discuss very briefly a few of the financial conditions surrounding American street railways. In the first place, I think a definition of a correct financial system of an operating property is perhaps necessary. When a man invests a hundred dollars in a share of stock he expects two things. He expects to get an annual return on that stock and he expects to get back his principal when he wants it, or at the end of the operating period. He takes his chances on the first, but he expects that the managers of a property will so conduct its affairs that if it becomes at any time necessary to wind up the existence of the company, he will get one hundred cents on the dollar for his investment. If a company is not able to do that it is not operating on a correct financial system. If it pays out too much in annual return and does not provide for contingencies which are likely to occur in any operating venture, trouble is likely to come. A correct financial system for the operation of the road is one where the investors are able at the end of the operating period to at least obtain their full investment, together with an annual return during the operating period if a return is earned.

Now that brings me to the subject of capitalization. I suppose that the old horse railroad systems prior to 1888, were capitalized very conservatively. I imagine there was very little water of any kind contained in their capitalization with a few exceptions. In fact, I think that in a large proportion of the systems, a good part of the earnings were turned back into the property and not capitalized. It is impossible to tell whether that is so or not. At all events the capitalization per mile seems reasonable and not excessive in any way. Now when electricity came into the field, as I said before, there was an exaggerated idea of its value as a profit earner.

There are two ways of capitalization. One is to capitalize on the basis of cost, and another on the basis of earning power. Both systems can be defended with substantial arguments according to the point of view. If you capitalize a system on costs, that is, strictly speaking, the correct system. The earning power then is a percentage upon the actual cost in the investment. If, however, the earning power should be, for example, 10 per cent., per annum, in a community whose safe investments yield but 5 per cent. per annum, on an average, and if its investors consider this particular street railway investment as sufficiently safe, they may pay two hundred for the stock instead of one hundred of a property which is capitalized on cost, and that is but another way of capitalizing on earning power. The investor depends on the earning power of the road to receive through a period of years a return of ten dollars a share, or five dollars per hundred dollars of investment.

Those who capitalized the street railways at the beginning, and in the continuing period of electric railway operation capitalized in many cases practically on earning power. For example, they found a horse railway property which was yielding to its owners a certain return on investment. Now these owners could continue operation indefinitely and obtain, we will say, 5 per cent. a year. Moreover, they could reasonably expect an increase of their income, particularly if they had been far-sighted enough to build for the future and for suburban business. Any syndicate proposing to buy that road naturally could not get it on less than a 4 or 5 per cent. basis. They would then find it necessary to discard 60 or 70 per cent. of what stood on the books as "assets," or "cost of road and equipment." The track would be of no use and the cars good for nothing. The horse railway barns, stables and buildings—practically all the property except the real estate—would have to be closed out at a selling value of not more than 10 to 20 per cent. of its book value.

Now it would be an extreme of purism in accounting to refuse to the syndicate the right to capitalize the cost of that plant, minus its selling value, plus the cost of the necessary investment for electricity. What the syndicates did, however, in many cases was this: Having bought these properties and put in electricity they issued bonds for the cost of the properties plus the cost of the electric equipment and reconstruction; they then issued stock which practically meant at that time little or no investment.

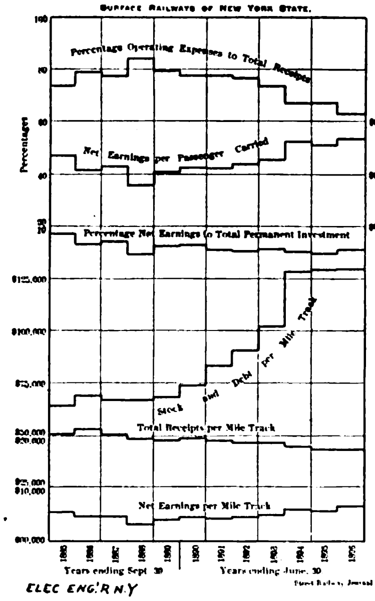

FIG. 4.

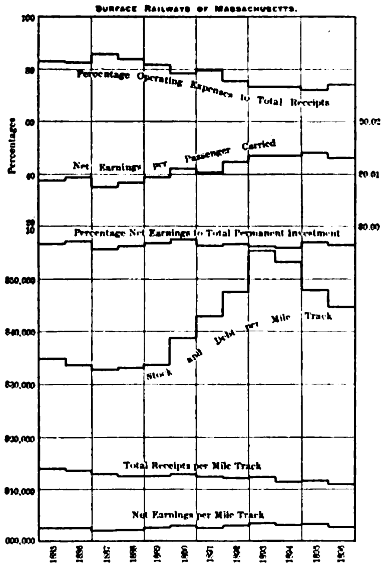

FIG. 5.

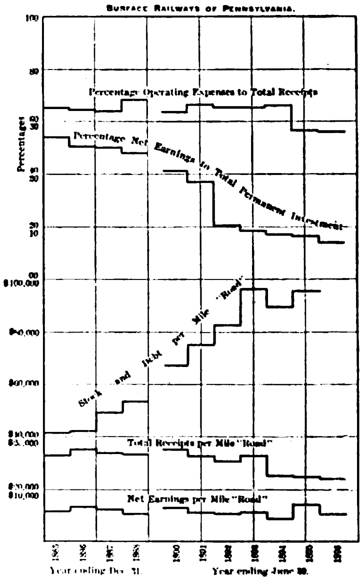

FIG. 6.

This method of capitalization was practised in a few cases, but by no means in a majority. In a large number of instances the old owners retained control of their properties, put on electric equipment, and simply charged up the net cost to their roads. But in the extreme cases where stock was issued without any quid pro quo, the present condition is that that stock does represent a very large investment in one form or another. The early equipment was very high priced—in the case of motors, four or five times present prices were charged and nearly double present prices for rails and other items of plant and equipment were usual. The equipment purchased at that time, moreover, was very poor, that is, it was insufficiently developed; the science of electric traction had not become fully understood and was more or less of an experiment in every sense. The result was that the syndicates had to put their hands into their pockets two or three years later, and buy new motors, frequently new cars, almost always new track joints, and now new rails. They had put a first mortgage on their property, and now had to create a floating debt, or capitalize earnings, or in other ways put more money into the enterprise, so that the cost of the properties to them to-day stands, I think, in a large majority of cases, at pretty close up to the total capitalization, including bonds and stock. In other words, there is to-day comparatively little over-capitalization of street railway properties except in certain isolated cases.

The result of electric traction has been an increase in gross receipts, a very large increase. If you will look at the diagram, Figs. 1, 2 and 3, you will see that in the States of New York, Massachusetts and Pennsylvania, which comprise over 30 per cent. of the entire mileage of the country, these gross receipts have grown at a very rapid ratio. At the close of the horse railroad period in 1889, the total receipts in Massachusetts were $7,500,000, and at the end of 1896, $14,852,000. In New York they were a little less than twice as much in 1896 as in 1889, and in Pennsylvania they were something more than twice as much as in 1889. The ratio of increase was small during the horse railroad period, the increase being fairly normal and due partly to increase of population, and partly to the increase in mileage. In the electric railroad period the growth was much more rapid, and was evidently due to the influence of electricity as well as increased mileage.

When you come to examine this increase carefully certain interesting results appear. In Figs. 4, 5 and 6 it will be seen that the gross receipts per mile of track have decreased in every State; in other words, as a whole, the street railways of New York, Massachusetts and Pennsylvania are earning quite a little less per mile, gross, to-day than they were in the horse railway period. Now, that is partly due to what might be called the generosity of the street railway companies in building for the future in the suburbs, and it is partly due to the increase of interurban traffic, which has a less earning power per mile than is the case in the cities, and naturally brings the earning power down. The gross receipts per car mile have also come down very materially, due again to the generosity of street railway companies in giving a much better service to the people either in increase of car speeds or in the greater frequency of cars.

It has been believed by street railway companies, particularly since the beginning of the electric era, that in order to get the maximum profits, you must give people frequent service; you must run cars at half the schedule intervals of the old horse railway era. That that has been, in a good many cases, overdone, there is no question. The companies have given a service which has brought the gross receipts down from 20 or 25 cents a mile to 15 or 20 cents. The more cold-blooded of the street railway managers have adopted a rule in some cases to govern their schedules by their receipts per car mile, or per car; in other words not to send out cars unless they are able to earn a certain sum per trip. There are various ways of looking at the policy of that method. In some cases, it is an absolute necessity.

The gross receipts per passenger carried have fallen off somewhat in the three States mentioned. Previous to 1890, they were, in all the three States, a very little in excess of 5 cents. They are now somewhat below 5 cents per passenger, but not much.

The changes in gross receipts per capita cannot at the present time be known except in one or two sections of the country, for the reason that we have very few reliable census figures of populations since the 1890 census, so that we do not know what the divisors should be as compared with the official returns in 1890.

When we come to operating expenses we find that in all cases, with very rare exceptions, the actual operating expenses have increased. The increase has not, however, been at such a rapid ratio as increase in gross receipts, and the consequence has been a reduction in the percentage of operating expenses to gross receipts, as seen in the diagrams. That reduction, however, is not only smaller than is generally supposed by those who have not looked thoroughly into street railway operations, but it is smaller than the figures will indicate; the reason for which I will presently explain.

In New York State the percentage of operating expenses which in 1885 was 73.9, in 1889, 79.4, was in 1896, 62.8, showing a very marked advantage in electric operation and one due almost entirely to electricity; but 62.8 is probably too low. In Massachusetts the horse railroads were operated at 82 per cent in 1885 and 1889, and 74.3 in 1896.

These figures are governed very largely by the extremely conservative, and yet, in some ways, not too conservative, policy adopted by one very large system in Massachusetts. In Pennsylvania the percentage has dropped from 65 and 68 to 55.5 under electricity. I am not able to tell how these extremely low operating figures for horse railway service in 1885-9 were obtained. I suspect they are quite delusive, and that the figures for electric railway operation are equally delusive. The Pennsylvania reports are not kept in the same way as the others, and allow more loopholes for differences in accounting methods than in the other two States mentioned.

The operating expenses per passenger have fallen somewhat, as may be inferred from the fact that with a uniform 5-cent fare, or practically so, the percentage of operating expenses to gross receipts has fallen. The operating expenses per car mile is a very delusive thing; it does not mean much of anything. It means something on any particular road when the results of one year are compared with another; it means almost nothing when different systems are compared with each other, the reason being that the expenses are, as I have already said, very much larger where a car can run only 80 miles per day, or at the rate of seven or eight miles per hour, than when run 150 or 175 miles per day, at the rate of fifteen miles per hour, since the "car service" portion of operating expenses forms a very large part of the total expenses. The cost per car mile is also governed by the length of cars, the carrying capacity, weight, etc., and therefore the cost of motormen and conductors per car unit, if we call a 16-foot car a unit. You can carry a hundred people with a thirty-five-foot car, with a single motorman and conductor, and the same number of people with a 16-foot car and two motormen and two conductors, the difference being very marked. The result is seen in such wide variations as 8 cents a car mile, and 27 or 28 cents a car mile, the fluctuations being usually within those figures. Such a road as the West End of Boston is operating at 25 cents a car mile, while a road with quite as great density of traffic, the Chicago City Railway, is operating at 14 or 15 cents a car mile. All these differences come in, and the car mile unit is a poor one to adopt.

I said a moment ago that the percentage of operating expenses to total receipts is delusive, as shown by the actual figures of a large proportion of roads, and in the totals of different States. That is due to this: In a correct financial system, as I defined it, you have to provide for the return of the principal to investors. Now when you start out with a new motive power about which you do not know anything, you should not pass to dividend account or to ordinary surplus account all the apparent net earnings of the first few years. Usually a large proportion of these apparent earnings represent depreciation of the new plant, and various contingencies, such as franchise life, etc. For example, a certain road commenced operation and after six months was able to present a profit and loss account showing operating expenses only 60 per cent. of the total receipts. Of these operating expenses, $2.94 only were for repairs and renewals.

That is, of course, ridiculous. We cannot hope that the life of the best roadbed put down to-day in our large cities, where the car traffic and wagon traffic is heavy, will exceed eight or ten years. In the heart of the business centers it may easily be not more than four or five years, particularly in the case of the special work. Now, during the ten years' life of the roadbed we must, if we are to maintain the capital unimpaired, not only pay the ordinary current repair bills for pushing up joints fixing the pavement and matters of that kind, but we must put aside enough money each year to provide a sum sufficient at the end of the life of the plant to replace it. It is an absolute necessity if we are going to maintain the capital intact. The same rule applies to cars, power station equipment, and every item of the installation. The cars, we hope, will last for twelve or fifteen years, although the electric service is pretty severe upon them. The motor trucks may last for ten years, but there is not a motor in operation to-day which is ten years old, I think; a great many have been discarded at the end of four or five years. The repair and renewal bills of electric railroads during the first six or eight years were something stupendous. The best apparatus known at the time was put in at the beginning of operation, but it was poor enough and had to be replaced. These replacements should properly be charged to operating expenses, but if that is done in any one year there is trouble at once. The best thing to do is to estimate the life of the various parts of equipment and provide for their depreciation.

When the people and newspapers see that a company is reporting expenses of 55 or 60 per cent. of the gross receipts and paying dividends of 6 or 8 per cent., it gives as a rule an incorrect idea as to the profits of street railroads. I believe street railroad managers are making a great mistake in not providing more largely than they are doing for inevitable depreciation, although it is true and sadly enough, in too many cases, that the interest charges alone take up a very large proportion of the apparent net profits, and there is little margin for proper accounting methods.

Now, we come to net earnings. The percentage of net earnings to total permanent investments will be seen also on these diagrams and will be found to be about the same to-day as they were under horse railroad operation in Massachusetts and New York, and very much less than they were in Pennsylvania. In other words, the enormous original investment, the cost of electric equipment and the cost of electric re-equipment and reconstruction of roads—all this experimental work added together has been large, and even though the net earnings have largely increased, the percentage on the investment has not increased, and it is more likely, I think, to slightly decrease than it is to increase in the future. I am inclined to think that the history of street railroading will be something like that of steam railroading, in that many of the companies will have to pass through reorganization periods in order to get down to a basis of fair earning capacity on the investment.

The net earnings per mile of track, as the result of the play of forces between the reduction in gross earnings per mile of track and reduction in percentage of operating expenses to gross receipts, is much the same to-day as under horse railroad operation. The curves in the diagrams show very little variation.

I wish now to speak very briefly of the probable conflict between electric railroads and steam railroads. We find that that conflict is much more likely to take place in the Eastern than in the Western sections of the country. In the Western section there is almost no interurban service and no conflict with steam railroads is likely except for a slight suburban business obtained by some railroads in a few cities. In the Eastern section, however, there are two networks, one of electric railway lines and the other of steam railway lines; and unless steam railways are more complaisant in the future than in the past, the conflict is going to be very severe. I think we will see electricity introduced on what are at present steam railroads to a very great extent in the States of Massachusetts, New York, Pennsylvania, New Jersey, Connecticut, and Rhode Island. I think that the solution of the problem which confronts steam railroads in the retention of their local business, which has always been a profitable one, lies in the adoption of electricity and the multiplication of stations.

PERFORMANCE OF THE COMPRESSED AIR CAR IN WASHINGTON.

MR. T. P. KANE, of Eckington, Washington, D. C., writes as follows to the Washington "Post" in regard to the compressed air car now on trial in that city:

The advocates of compressed air, who claim for it a dangerous rivalry of electricity, could have witnessed a practical demonstration of the superiority of the latter to the former had they been at the corner of R street and Eckington place on Tuesday evening of this week.

As the air car, now on trial on the Eckington line, was making its return trip on the evening stated, after its customary run of about a mile and three-quarters from the power house to the Treasury Department, it became hopelessly stranded in ascending the short grade of the half-square between Quincy and R streets and was unable to reach the top.

Under the skillful manipulation of the lever and brake by the expert in charge of the car every possible effort was made to force it up the grade, but without success. The car was backed and forwarded several times, but each attempt to reach the summit resulted only in its getting farther and farther down the hill. Finally in despair the receiver of the road, who was on the back platform of the stalled car, directed the conductor, sotto voce, to signal the trolley car, which was a short distance in the rear for assistance, and electricity, responding promptly to the call of its competitor in distress, came to the relief of compressed air and with perfect ease pushed its heavyweight rival up the hill and over the curve to the downward grade beyond.

I have been on this air car a number of times when it was barely able to reach the top of the grade at this point and had heard of several similar "hold-ups" which it had experienced at this same place, but I mention this particular instance simply because I happened to be present on the occasion stated and witnessed the occurrence above described.

The most noticeable peculiarities of this air car are its evident aversion to grades in general and a decided tendency to get winded when forced to climb a hill, all of which goes to support the doubt expressed in my recent criticism in the "Post" of the air motor experiment as to the ability of this car to make one round trip over the Eckington line. I mean by a round trip the course followed by the other cars on the line, from the power house to Brookland, from Brookland to the Pennsylvania Railroad depot, and back again to the power house, a distance of probably less than seven miles, and a trip which this car has never attempted to make.

SAFETY APPLIANCES ON RAILWAY GENERATORS.—SOME LIGHT ON THE MT. VERNON STATION FIRE IN PHILADELPHIA.

BY GEORGE MOFFAT.

Of the many fires which have lately destroyed power and lighting central stations, none have been investigated, that I am aware of, to find if the calamity could have been prevented, and, if so, how.

We find in the majority of stations now built a want of balance about the system; either the machinery may be the best money and labor can procure, while the building is simply a rude covering and the switchboard apparatus is of the crudest kind. Then, again, there are at least three stations in the East which have cost the owners considerably more than the machinery they contain. There is no serious objection to this, excepting one is generally done at the expense of the other, for buildings may be of brick and stone to be perfectly fireproof while the generator is left unprotected. There are others which have all the latest safety (?) devices and still the building itself is an invitation for the spark to complete destruction.

But let us look into the manner the machine itself is protected in our large stations. The last large central station fire—that of Mount Vernon station, Philadelphia Traction Company—will serve as an illustration.

When this station was built the first generator (400 kilowatt) had the circuit breakers put up on the negative side, which is the usual way. New machines (1,100 kilowatt) were installed in the fall of 1894, but as they flashed very badly the makers thought it advisable to break the positive side so as to stop excitation. Equalizer jaws were put on the breaker and it was also broken and the breaker taken off the negative side and from the switch, which leaves a complete negative cable from machine terminals to negative bus bar. The negative side of the machine was connected to the coil that releases this interesting (!) piece of mechanism. This can easily be understood by referring to Fig. 1.

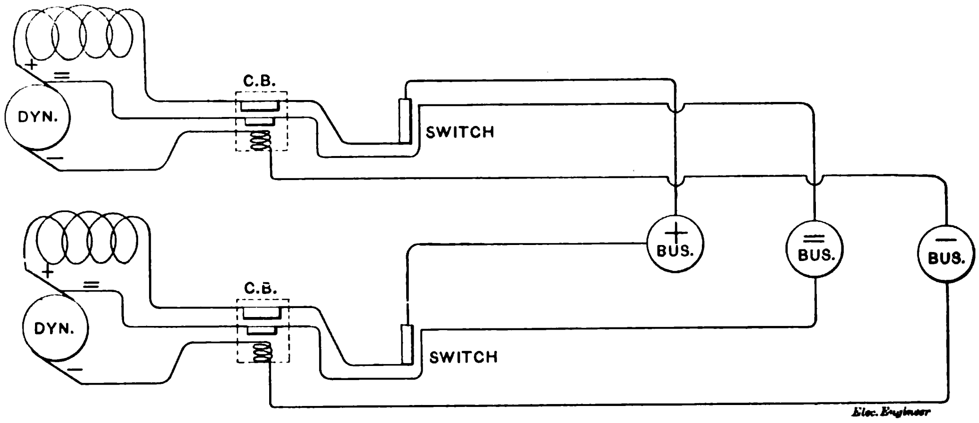

Fig. 1.

The evils of this combination were soon apparent. The author, who had charge of this station at that time, immediately put fuses on the negative side of the machine. Their utter unreliability in railroad work is too well known to be further discussed. It is sufficient to say that one fuse rated at 100 amperes was connected in series with a feeder circuit breaker loaded to 400 amperes and opened the breaker; and at another time the fuses on the machines (1,500 ampere fuses) melted at a load of 700 amperes. Accidents of this kind leave the machine disabled for a few minutes, overload the others and, the chances are, open the breakers and shut the station down. They were taken off soon after. Circuit breakers were next proposed and were to be fastened on the machine, but as the machines were not working well, it was decided to get entirely new ones and place the circuit breakers where they belonged—on the negative side.

The first of these new generators was in process of construction at the time of the fire, March 3, 1897. The fire itself was occasioned by a dangling crane chain short circuiting the positive to ground through the fly-wheel. The particles of molten metal thrown over a greasy floor soon accomplished the mischief.

Fig. 2 shows how the short circuit occurred, also the location of circuit breaker located on positive side, which no doubt opened, as the other machines would tend to open it, but still leave the unfortunate machine unprotected. Had the breaker been where it should have—on the negative side—this could not have happened, as it would have opened and the worst would have been an idle machine for two or three minutes.

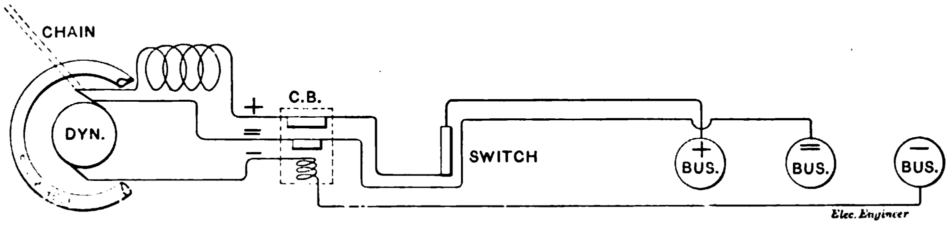

Fig. 2.

Added to this was a wooden floor (which has no right whatever in a central station), dangling chains and unprotected machine terminals—a pretty combination.

Another source of danger in many stations is grounded field magnets. There is not one good reason why field magnets should be grounded. In fact, all the arguments are against such a proceeding, and yet some makers of electrical apparatus are making them so. Possibly the cheapened cost of construction may have something to do with it. It is not enough that they should be put in position properly insulated, but they should be kept so. An insulation test with a voltmeter should be made at least once a week and all oil, dirt, dampness, etc., wiped off the base. This may prevent serious trouble should a field coil prove defective.

What is needed is not new safety appliances but the proper use of those we have, added to scrupulous care.

A SPOUTING TROLLEY POLE.

The spectacle of a sizzling fountain of water, springing geyser-like from the top of a trolley pole drew a crowd of wondering people at the corner of Michigan avenue and Third street yesterday. They looked on with almost as much amazement as the Israelites might have experienced when Moses worked his miracle with a rock and a walking stick. A gang of workmen set to work to discover the occasion of the phenomenon. In the course of time they came to a waterpipe, which ran beneath the pole. It had been eaten through with electrolysis, and the water burst through, entered the hollow trolley pole, and having nowhere else to go, came out at the top.—Detroit Evening News.

SUBURBAN ELECTRIC LINE FOR MONTREAL.

A big electric railway scheme is planned to connect Montreal with many near-by points across the river. The road will probably be called the Montreal and Southern Counties Railway. The idea is to connect Montreal and the south shore with the counties of Chambly, Vercheres, Ronville, St. Hyacinthe, Laprairie, Brown, Shefford, Stanstead, and Sherbrooke. From Montreal and Sherbrooke the main line and branches will form a system of 150 miles of track, and the road is to be constructed on the most approved methods. The trucks will be built in such a way that the cars run as fast as forty miles an hour. A. J. Corriveau, who is associated with a New York and Montreal syndicate, has the scheme in hand, and from present appearances there is said to be every prospect that it will go through. The capital of the company is $2,000,000.

MECHANICAL

THE WELLINGTON ENGINE.

BY IRVING A. TAYLOR.

I BEG to remark the fact that this engine, described in your issue of April 21, 1897, is merely a complex variation of the ordinary, every-day steam engine; and though I have not the time to go into a general analysis, a few words will be sufficient to make it evident that the efficiency is as low, if not lower, than usual.

For the first matter, that of non-originality. The boilers are the same as ordinary boilers and are not necessarily more efficient, while practically they would be less so when the inefficiency (due to loss of heat by radiation, chimney gases and other ordinary losses) of the prime boiler marked "Heater" is considered. The discharge into the "cooler" could just as well be into a river, while the feed from "cooler" could be from a river. The condensers would be called, if used for a non-condensing engine, feed water heaters.

Since the cases are parallel, does any one suppose it would be economical to keep a high pressure (40 lbs. absolute, for instance) in their combined condenser feed water heater, in order to obtain feed water at a high temperature? Or would it not be more economical to use the water from a river (the "cooler") for each condenser separately, thereby securing low back pressure, and heat the feed water to 288 degs. Fahr. by an economizer placed in the chimney of the furnace under the "heater"?

The use of a fluid with a low temperature of evaporation, i. e., a two-fluid engine, has been tried several times and found to be practically inefficient. (See Wood's "Thermo-dynamics.")

Now, looking at the matter of efficiency. The "heater" supplies, per pound of water passing through it, 500—288 = 212 H. U. The engines take 500—220 = 280 H. U., and deliver through condensers 288—50 = 238 H. U. They therefore use 280—238 = 42 H. U. The difference between 212 H. U., supplied by the "heater" and 42 H. U., used in the engines, i. e., 170 H. U., is the amount, 220—50 = 170 H. U., thrown away in the "cooler." The theoretical limit of efficiency of the engines is 42 ÷ 212 = .198 = 19.8 per cent. If the efficiency of the "heater," boilers, condensers, piping, and the mechanical efficiencies of the engines are taken into account, this figure would easily be reduced to 6 per cent., or less.

It may be laid down as a law, that, to be successful, any complicated apparatus must offer as an offset for its complexity, some great advantage, such as a very evident increase in efficiency.

The cost of coal per horse-power hour in a good condensing plant is not over 3-10 cent, while the attendance, interest, depreciation and repairs, brings the cost up to from 2 cents to 10 cents per horse-power hour, depending on the load factor and size of plant. It evidently will not pay, even for a 50 per cent. decrease in the coal consumption, to increase the other expenses by 10 per cent. In the case of 2 cents per horse-power hour, or 2 per cent. at the other limit of 10 cents per horse-power hour.

LETTERS TO THE EDITOR

CARELESS OVERHEAD WIRING.

AN instance of poor line work has come to our attention on one of the alternating systems now operating in Philadelphia. One day recently during a stormy day, a primary wire became crossed with the secondary, and either from poor insulation or through dampness 1,000 volts was sent through the secondary, and came near causing the death of a young man who was working in a store which the secondary supplied.

The young man went to the cellar and reached up to turn on the light; upon touching the brass part of the socket he received a shock which may cause the loss of three fingers. He lay in the cellar fully fifteen minutes unconscious. He was taken to the hospital and is now undergoing treatment.

The electric light company claimed that the accident was due to a ground, but upon a thorough test of the installation it was found to be clear of all grounds, and, what was more, after the test by one of their own employés, when the man went to slide up the canopy of the fixture he was knocked off the ladder.

A thorough search soon placed the blame where it belonged. One of the company's men got up the pole and found the cross not one foot from the converter, and yet the company claim they do good line work. Why does not the city make the companies having high tension lines do good work or hold them responsible for all accidents which may happen, due to their carelessness?

The large number of just such accidents should lead to the employment of competent and careful linemen, who would have some regard for the safety of the company's consumers and the public at large.

Thorough inspection of nearly all lines would probably reveal just such traps as these waiting for some unsuspecting person to walk into.

D. W. G.

MARRIED

CONOVER-GREENE.

The marriage of Miss Mary Richmond Greene to George Stevens Conover occurred on April 21 at St. George's Church. The ceremony was performed by the Rev. Henry Lubeck, rector of St. Timothy and Zion Church, New York, assisted by the Rev. J. Phillip B. Pendleton, D. D., rector of St. George's. The bridesmaids were Miss Downs of Philadelphia, Miss Conover of Princeton, N. J.; Miss Vincent of New York, Miss Page of Boston, and Miss Campbell and Miss Franchot of Schenectady. The best man was F. S. Conover, Jr., of Texas; the ushers, R. S. Conover of Hyde Park, N. Y.; E. F. Conover, A. B. Shepard, F. V. Blackwell, W. L. R. Emmett, J. W. Kirkland, George De B. Greene of Schenectady, and C. L. Perrine of Boston. The attendants upon the bride were four little cousins, Gertrude, Edith, Katherine and Eleanor Greene, daughters of Col. Greene of New York. The bride is a daughter of the late Capt. S. Dana Greene, United States Navy, who commanded the Monitor after Lieut. Worden was disabled, in her famous engagement with the Merrimac, and sister of Mr. S. D. Greene, general manager of the lighting department of the General Electric Company. The bridegroom is chief engineer of the construction department of the General Electric Company.

VOL. XXIII. NEW YORK, APRIL 28, 1897. No. 469.

Notice of Removal.

THE ELECTRICAL ENGINEER

is now occupying its handsome and commodious new suite of offices, entire south wing, eleventh floor, of the Beard Building, 120 Liberty street, New York City. It is not only thus most advantageously situated at the heart of the machinery and electrical district, but enjoys an increase of several hundred feet floor space. The offices are convenient to all railroads and ferries, and an invitation to visit them is cordially extended to all friends and patrons of the journal.

HIGH SPEED TELEGRAPHY.

THE telegraphic art, at least in the United States, has for a good many years been criticised on the score of non-progressiveness and it has been alleged that in the application of improved methods foreign nations for once have left us in the rear. This is not pleasing to contemplate and it seems worth while to consider a little more closely this state of affairs to determine if possible the causes to which the existing conditions may be ascribed. As a matter of fact, the telegraphic art has not been wholly at a standstill in America. This country was the first, we believe, to apply the dynamo as a substitute for the gravity cell, due to the enterprise of Mr. Stephen D. Field, and to-day America leads in the number of such installations. The quadruplex in its present form may also be claimed as ours, due to Mr. Edison; and other, by no means unimportant, improvements in methods and apparatus could be mentioned which have found their way into universal practice. But the fact remains that the Morse key and sounder still continue to be the ways and means of handling more than 99 per cent. of the country's telegraph business. Machine telegraphy can therefore hardly be said to have obtained a foothold here, in spite of the able inventors who have submitted their systems for public approval, among them Delany, Craig, and others. The newest comers are Messrs. Crehore and Squier, whose experiments in timing the flights of projectiles led them to the construction of their polarizing photo-chronograph out of which they have developed a decidedly ingenious system of telegraphic transmission by means of alternating currents. Their system as described by them before the American Institute of Electrical Engineers last week presents a most interesting study and though not yet beyond the experimental stage, is worthy of consideration. We may say, in passing, that the inventors have taken several leaves out of Mr. Delany's book, to whom, we are glad to note, however, they give full credit.

At the conclusion of their description of the apparatus employed by them Messrs. Crehore and Squier enter into a discussion of the place which a system of telegraphy capable of transmitting several thousand words a minute would have in the commercial world, in which they give a very instructive table showing the statistics of the United States mail service, the telegraph and the telephone. They bring these forward to show first how inexpensive the present mail is as compared with the telegraph and telephone and, on the other hand, how expensive the telephone is as compared with the telegraph. A high speed telegraph system, such as that elaborated by Mr. Delany and submitted to a Congressional committee some months ago, could, they believe, take largely the place of the post. It will be conceded even by the advocates of high speed telegraphy, that, however meritorious a system of high speed telegraphy may be, it will, of necessity, be limited to trunk line business, and that most of the way business will continue to be done by the Morse system.

This, however, is no argument against high speed telegraphy, but is only brought forward to emphasize the point that no system of high speed telegraphy has yet been exploited, applicable to all kinds of telegraph business. Nor is it the intention of the advocates of such systems to impose such conditions upon themselves, preferring, as they do, to cater for the most remunerative business. What has just been said is not intended in any way to convey the impression that high speed telegraphy is not worth striving for. On the contrary, we know of no more desirable goal to aim at in the art of transmitting intelligence, and any means brought forward to accomplish that end ought to be welcomed and encouraged. But before that end is reached, it seems to us that other hitherto neglected matters in telegraph work must be looked to, and principal among these is the line. Even the best constructed pole lines built, according to existing practice, are subject, one might say, to hourly disturbances of one kind or another, while not infrequently an entire system of wires is rendered absolutely useless by the destructive elements. Where a line fails temporarily as is frequently the case, the receiving operator's break at the other end informs the transmitting operator of the fact, and the unintelligible part is quickly rectified. But a line disturbance lasting for only five seconds, say, on a line handling 3,000 words a minute would mean a "break" of 250 words, and, what is worse, would not be discovered until perhaps thousands of words had been reeled off beyond it! The condition of affairs under such a régime can more easily be imagined than described. The first thing to be looked to in high speed transmission, it would seem, therefore, is the construction of a line which would be reasonably safe against interruptions of even the most temporary character. Such a line can be built but would, of course, require to be very much more substantial than the present types, and would probably run through a right of way not less than thirty feet wide and clear of all trees and other like disturbing environments. The cost of such a right of way would be to a considerable extent offset by the reduced number of wires demanded with high-speed telegraphy, and by the reduced cost of repairs. If a line such as here contemplated were in existence to-day we have no hesitation in saying that at least one of several high-speed systems would be immediately available. As to the effect of the inauguration of such a system on the present business of the telegraph and telephone companies, we have no hesitation in expressing our belief that it would be beneficial to both. We need only point to the business of the telegraph companies which has, after all is said and done, steadily increased since the advent of the telephone. Each service will command a distinct patronage and there will be room for all. It is to be hoped that private enterprise will take up this work and thus leave the government free to concentrate its efforts on the very defective mail service; but there is great danger that unless some move in this direction is made by existing or by new companies, the government may be forced to take up the matter in response to public demand. This would be highly regrettable.

ELECTRIC BURGLARY WITHOUT THE CURRENT.

THE public was recently alarmed by reports from Chicago of the easy manner in which the burglar of the future will use electric current as the means for penetrating into bank safes and vaults where valuables are kept. Our discussions of the subject have shown how little value need be attached to these sensational stories, and now comes an incident that tends to disprove some of the more subtle theories set afloat. It was urged, for example, that many burglars are expert mechanics and can easily acquire a knowledge of electricity or would graduate from the electrical ranks; so that they would utilize electric heat as readily as a fishmonger uses ice. Previous experience had gone to show, however, that when the burglar went a-burgling he preferred to have all the currents of electricity cut off, and the latest episode proves that this type of human leopard has not yet changed his spots. It appears that the foreman of an electric light plant in this State was discharged not long ago as a bad character, and that his dismissal was soon followed by sudden stoppages of the electric light, attended by a number of petty thefts. A detective was engaged, who soon trapped the man into an avowal of his ability to be bold and bad by engaging him to run a crooked pool and card room. The information was next volunteered by the ex-foreman that he had a plan of the local National Bank and knew how easily it could be "cracked." His plot involved the disabling of the electric light plant so as to leave the town in darkness; and he took the detective with him to the station and actually gave some whisky with "knock-out" drops in it to the night engineer. The drops took effect, and while the man was still under their influence the lighting circuits were thrown off. Next day the ex-foreman and his ally, a drug clerk, who had compounded the drops, were arrested for the offense of drugging, which carries with it a penalty of fifteen years' punishment. This is certainly a very interesting episode, but, as will be seen, every condition was favorable for just that burglarizing by means of electric heat we have heard so much about. Yet, it will be observed, this expert in electricity and crime did not want any electric heat in his scheme. His one idea was to get the current turned off, not to get more turned on; and even the preliminaries of opening the circuit have put him in peril of fifteen years' imprisonment.

THE ELECTRICAL CONTRACTORS' DINNER.

HARMONIOUS and successful in every way, the annual dinner last week of the New York Electrical Contractors' Association was something more than a mere occasion for feasting and oratory. It served to show how large and important a field of work had grown up within the past few years, and how great are the interests now engaged in the task of equipping a big modern city with electricity. Nothing has of late been more remarkable than the creation, not alone of the Greater but of the Newer city on the Island of Manhattan and its adjacent territory; and even the citizen who witnesses daily the work of rapid construction is impressed with the number, loftiness, size and beauty of the new buildings. The electrical contractor is entitled to the credit for much of the difficult work that has made these shining palaces possible, and the high standard always kept in mind was emphasized by the dinner and by the speakers. As President Hatzel pointed out, with labor troubles in the background, the association has important duties and objects none of which is more vital or laudable than that of setting up a high ideal of excellence and requiring all its members to maintain and advance it nearer to perfection. It is evident that the contracting business is expanding—still undergoing development, as suggested by Messrs. Johnson and Mailloux, on the one hand toward "bulk" contracting and on the other to a helpful supervision by the consulting engineer; in other words, an increase and a decrease of direct responsibility. Under such conditions and in view of the others still to arise, it is well that a strong and authoritative body should exist, whose efforts for unanimity on the right lines will do more good than all the multitudinous rules that are incessantly promulgated.

TELEPHONIC CONVERSATION AS EVIDENCE.

LAST week we made note of the fact that Judge Bundy, in Indiana, decided to admit a telephonic conversation as evidence, although he could find no precedent or authority in the books. A correspondent of the Sun, who writes apparently with some authority, asserts that there is authority and that the first admission of such evidence was in the famous Ferdinand Ward suits, when his "partner in crime," J. D. Fish, swore to instructions received by telephone as to the disposal of two checks for about $146,000. The evidence was admitted by Judge Barrett, as was also that given next day by a brother of the witness, to the effect that standing near the telephone he had heard Ward's voice distinctly. The lawyers for the defence of Ward objected, but a letter from Ward to Fish was put in evidence complaining that everybody in the room where that telephone hung could hear what was being said. Ward was found guilty of fraud, and Judge Barrett's decision in regard to the telephone message was sustained on the appeal. The Sun has quoted a precedent furnished three or four years ago in this city by Judge Benedict; so that here we have three authorities all accepting telephonic conversations as good evidence.

The telephone being thus established, the attempt to give a footing to the phonograph or graphophone may be noted. An action having been brought against the New York Central for damage from the noise caused in building its new viaduct uptown, three graphophone cylinders were produced in the court, alleged to bear record of the noises, so as to furnish the court with auricular evidence. Judge Truax ruled that he could not admit the evidence, at least at this stage. This would imply that it may manage to slip in later; and in the meantime this would appear to be the first time that an attempt has been made to secure acceptance by the courts of such testimony.

THE disastrous fire which destroyed the Mount Vernon street power house of the Philadelphia Traction Company a short while ago has attracted more than usual attention among railway men. The origin of the fire is primarily ascribed to the fouling of the crane chains with a generator, causing a short circuit; this was followed by the throwing of molten metal on the oil soaked floor, which did the rest. But the cause of the continued short circuit had not thus far been explained. Just how it came about is now shown in a communication, appearing in another column, which ought to prove of value to all railway power station superintendents.

THE Citizens' Street Railway Company of Indianapolis has come off signally victorious in its fight against the new three-cent fare law, noted by us last week. Judge Showalter in the United States Circuit Court at Chicago has declared the law to be unconstitutional because it is "special legislation," applying only to the city of Indianapolis and to no other part of the State of Indiana. The court holds further that where proceedings in effect destructive of vested property rights are threatened by a defendant in an official position under color of a void statute, a preliminary injunction ought to issue; and it has been granted. As a matter of fact, there are three injunctions: one preventing the company from receiving three-cent fares; one against the State Prosecutor forbidding him from any attempt to enforce the law, and one against the city to prevent its officers from trying to put the law in force. This is pretty complete in the way of choking off the unconstitutional legislation, and the company goes back at once to five-cent fares.

AN important "deal" that has been under negotiation for a long time past has just been brought to a successful issue. The Postal Telegraph Company has been without a Mexican connection and the Mexican National and Mexican Central railroads have been able only to send messages over their telegraphic lines to this country by way of the Western Union Cable between Vera Cruz and Galveston. These interests have therefore got together and have made a 25-year agreement to exchange business, and the Postal lines which have lately been pushed in Texas will now be carried through to Laredo and El Paso on the Mexican side. The Commercial Cable Company will naturally handle all the European business coming and going, and thus the line of communication will be complete. There will probably be no cutting of rates, as that is contrary to the policy of the competing companies, but the elimination of the cable may make a difference in favor of lower cost.

IT is stated that the creditor of a Western street railway sought to make the enforcement of his claim swift and emphatic by levying on all the motormen's switch handles, without which it would obviously be a very hard thing to run the cars. The upshot of the affair is not given, but it seems to us that aside from the meanness of the plan, it is wholly irregular and illegal. If it is improper for strikers to stop cars because they carry mails, it would appear even more improper to let anybody interfere in a suit for debt, with cars carrying not only mails but passengers, and subserving the necessities of a large population. There ought to be some better way out of the difficulty.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—VII.

BY JOSEPH APPLETON. (Copyright, 1897.)

INSTALLATION, CARE AND MAINTENANCE OF STORAGE BATTERIES. (Continued.)

THE value of this test in practical work, is to ascertain whether at the end of a discharge or charge, when the voltage of the cell has reached the limit, both plates are in similar condition or if one is behind.

It will be noticed, from the readings given, that at the end of a discharge the voltage between the cadmium and negative should read .23 to .33, according to the rate of discharge, the cadmium being negative; this requires very accurate measurement on account of the comparatively small difference in potential; therefore, the best way to make the test is as follows:

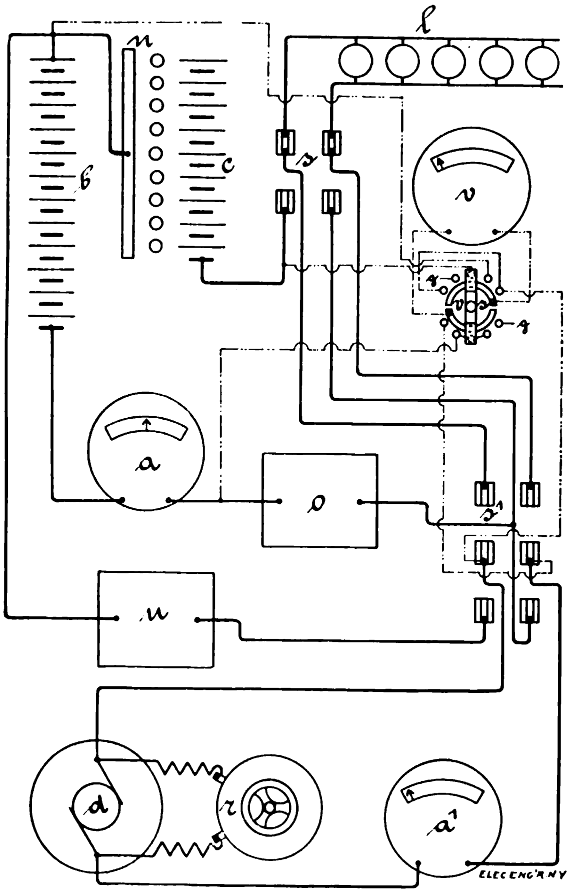

FIG. 21.—DIAGRAM OF CONNECTIONS FOR COUNTER CELL REGULATION.

a, a^1, Ammeters ; b, Battery ; c, Counter Cells ; d, Dynamo ; l, Lamp Circuit n, Counter Cell Switch ; o, Overload Switch ; u, Underload Switch ; s, s^1, Knife Switches ; v, Voltmeter ; v s, Voltmeter Switch ; r, Dynamo Field Rheostat.

At the end of the discharge when the voltage of the cell has dropped to the limit, measure the e. m. f. between the positive and negative plates, also between positive and cadmium.

The difference between these two readings will give the e. m. f. between cadmium and negative; for example:

E. m. f. of cell.	Cadmium and positive.
1.88	2.10

Subtract one from the other, .22, which shows the condition of the negative.

A negative plate should never be discharged beyond the point where the e. m. f. between the cadmium and negative reads .30, except at high rates of discharge, when .35 may be considered the limit.

If the voltage of the cell drops to the limit before the negative reaches this point it is the positive plate which is exhausted.

In the same way during charge this test will show if both plates are fully charged when the voltage of the cell reaches the proper point, which in ordinary work may be fixed when the reading between cadmium and negative is zero, or in other words, when the voltage of the cell, and the reading between the cadmium and positive agree.

During the early stages of storage battery work, when its use was considered more or less of an experiment, the manufacturers found it necessary, in order to sell them, not only to guarantee satisfactory operation, but also that the cost of keeping them in repair would not exceed a certain sum per annum. This custom, once established, became a recognized part of all storage battery contracts and in many cases was an injustice to the manufacturer, as the purchaser neglected the battery, feeling that he was protected under the maintenance contract.

In large central station plants, where the size of the battery is such that proper attention is given to it, the guaranteed maintenance is a fair and equitable arrangement, but in many isolated plants the battery is neglected and it becomes a question of guaranteeing the man in charge as well as the battery. No other class of electrical machinery calls for such a guarantee, in fact, such an arrangement would not be considered for an instant by the manufacturer. It is simply because the action of the storage battery is silent and invisible that the makers have to guarantee something, which in many cases is beyond their control.

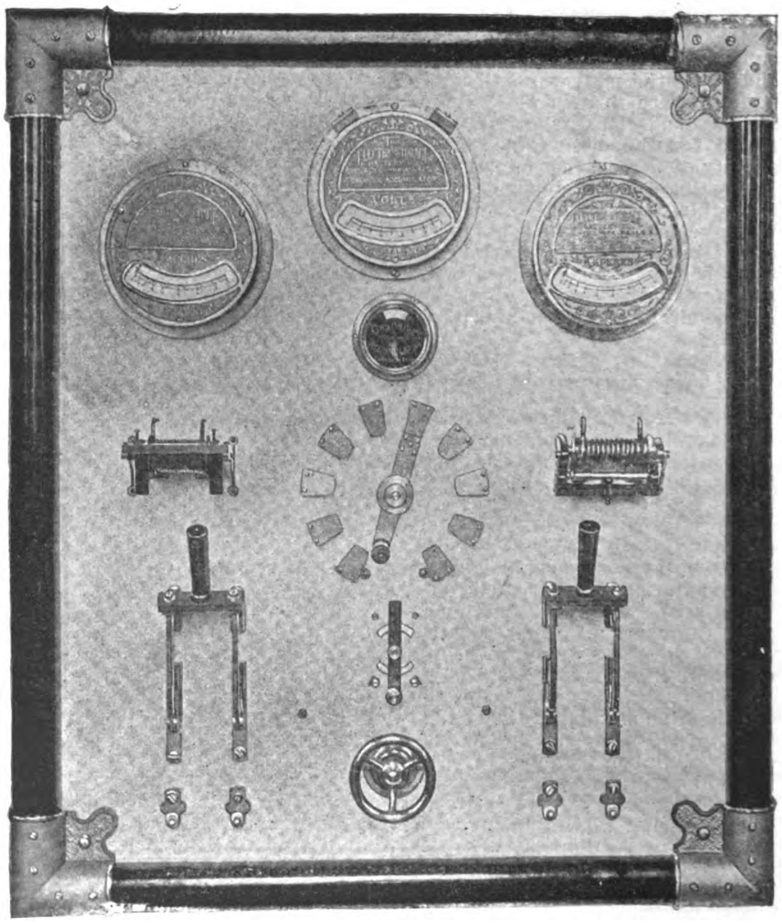

FIG. 22.—SWITCHBOARD FOR COUNTER CELL REGULATION.

With the modern storage battery and a reasonable amount of attention, the cost of maintenance is considerably less than that for which the manufacturer will enter into a contract, and these facts tend to discourage the adoption of such contracts except in large plants where the amount of money invested is considerable and the manufacturer has reason to know that proper attention will be given to the battery, and therefore is enabled to make a low maintenance contract.

In the majority of plants the owners could maintain the battery for a much smaller amount than the manufacturers charge, if they gave it proper attention, as the manufacturer has to allow for the possibility, if not the probability, of the plant being neglected. It is much better all round for the owner to maintain his own plant, if proper attention is given, as the battery is benefited by having regular attention; the owner saves money and the manufacturer is relieved of the responsibility.

APPLICATION OF STORAGE BATTERIES TO ISOLATED PLANTS.

In considering the application of storage batteries to isolated plants, we will divide the latter into two classes, and consider them separately.

1. When the isolated plant is installed in a private residence or similar situation, where convenience is of more importance than economy of service.
2. When the isolated plant is installed in an office building, or other business premises, where economy of operation is the chief point to be considered, the entire system being in competition with other methods of lighting and power.

In the first case, the storage battery is usually the principal feature of the system, all the light and power on ordinary occasions being obtained from it; the function of the generating plant being to charge the battery when necessary. This method of operation is simple and convenient, and eminently suited to the class of work, for it gives a continuous supply of electricity without the necessity of running the generating plant, except when the battery needs recharging.

The motive power in plants of this character is usually a gas or an oil engine, both of which are specially suited for intermittent running, and can be started up on very short notice. Steam engines are not so suitable for this purpose, as they require constant attention, and cannot be started up quickly; it is only where a large number of lamps have to be run for a considerable time that the conditions justify the regular attendance of an engineer.

A storage battery makes an electric light plant of this description possible, and even essential, for a private residence when it would be otherwise entirely unsatisfactory, as direct lighting from a gas or oil engine is impracticable except under special conditions.

The best arrangement of an isolated plant for this class of work is to have a battery capable of supplying one-half the lamps wired, for eight to ten hours on one charge. The average use is considerably less than one-half the lamps wired, therefore a battery of this size will take care of the ordinary requirements for two or three days on each charge.

The capacity of the engine and dynamo should be equal to that of the battery at the eight-hour discharge rate, so that on special occasions when all the lamps are required the battery and generating plant can be run together and supply all the lamps for a miximum of eight hours.

There are two or three ways of installing and operating a plant of this description, but it depends entirely upon the local conditions which will prove the most satisfactory. For installations up to a capacity of 200 16-candle power lamps the best arrangement is a plain shunt wound dynamo capable of generating up to 150 volts, the pressure required for charging a battery operating a 110-volt circuit.

When the engine is belted to a gas or oil engine it should be provided with a fly-wheel pulley to maintain a constant speed under the irregular running of the engine, due to the sudden impulse of the explosions; the engine should also carry as much fly-wheel as the design will permit. A battery of 58 or 60 cells is required for 110-volt lamps, so that the full voltage may be maintained until the end of the discharge.

The best method of regulation for a plant of this size, is by counter electromotive force cells, placed in the circuit between the battery and lamps. These counter electromotive force cells are composed of plain lead plates mounted in a containing cell in exactly the same manner as the positive and negative plates in an ordinary cell, and give a counter electromotive force when the battery is discharging through them, averaging from 2.2 to 2.5 volts, according to the amount of current passing.

It will readily be seen that by keeping the right number of these counter cells in circuit between the battery and lamps, the voltage of the lamps can be maintained at normal pressure irrespective of the voltage of the battery. Sufficient counter cells must be provided, so that if any lamps are being used when the battery is charging, and consequently has a higher voltage, the voltage on their circuit can be maintained at the normal. For example, if 110-volt lamps are used and the maximum voltage of the battery while charging is about 150 volts, the difference of 40 volts has to be absorbed by the counter cells. It is found in practice that 18 counter cells are sufficient for all purposes. When it is possible to avoid using lamps while the battery is being charged—and this is feasible in most private installations—the number of counter cells can be reduced to seven, these being sufficient to regulate the voltage during discharge.

Fig. 21 shows diagram of connections for a plant of this description, and Fig. 22 illustrates a convenient arrangement of switchboard for same. The necessary instruments and apparatus are as follows: Voltmeter with 5-point switch, arranged to read pressure of dynamo, battery and lamps, also to be used as a ground detector. Ammeter in dynamo circuit. Ammeter in battery circuit, reading current in both directions. Counter electromotive force cell switch. Knife switch for dynamo. Knife switch for battery. Automatic underload switch to open circuit when the charging current falls to zero, thus preventing the battery discharging back through the dynamo. Automatic overload switch to open battery circuit when the battery is discharging at too great a rate. Rheostat for shunt field of dynamo.

With the above arrangement of apparatus the plant can be operated and controlled as desired.

ALTERNATING CURRENT DYNAMOS IN PARALLEL.—I.

BY J. E. WOODBRIDGE.

THE advantages to be gained by the parellel running of alternating current dynamos are just beginning to be realized by electrical central station managers. The complications caused by the present prevailing system of running each machine on a separate circuit become very serious and annoying in the case of large stations where there are a large number of generators. The number of circuits increases necessarily with the number of machines, and the problem of properly distributing the loads on those circuits so that in the evening each generator shall do its full share of the work, and yet not be overloaded by some unanticipated addition, is a serious one. A compromise which results in poor economy always has to be made with loads which are subject to sudden changes that cannot be foreseen in the central station, such as theatre and church loads, etc.

Then constant attendance is necessary, as the load rises and falls through its daily range, to start up the fresh dynamos as they are needed, and switch on to them the different lines; and again, when the load falls off, to properly bunch the lines on certain dynamos, so as to keep the machines which are running always as near to their most efficient loads as possible. No little ingenuity is needed when the dynamos in the house are of various sizes and capacities. When the conditions are further complicated by the necessity of giving the longer feeders a higher voltage than the shorter ones, the increase in that voltage being proportioned roughly to the load, the switchboard man has no easy job. Added to that is the necessity of carrying over his circuits as nearly instantaneously as possible, to prevent too long a "wink" in the lights; and the risk of accidentally throwing two machines in multiple by a mistake in the manipulation of his switches.

The case is worse than the handling of a similar number of dynamos in parallel, as they are arranged, for example, in Edison stations; because in the latter case all the circuits being multipled, the various fluctuations of the different individual loads tend to even themselves up, and being small in comparison with the whole multipled load, give far less trouble. There is also but one load to watch, which, if the machines are well designed, automatically distributes itself evenly among them, while on the independent system there are a half dozen or a dozen different loads, each of which must be looked out for.

The winking of lights in switching is another disadvantage of the independent method of running alternators. To the critical customer engaged in reading his evening paper, the sudden darkness of two or three seconds' duration and the jumping of the lights, as the grouping of the switches is changed, are great nuisances, and are likely to cause some remarks concerning the comparative steadiness of the Welsbach gas burner.

These disadvantages are eliminated by running all the alternators in a station in multiple on one set of bus-bars, from which all the feeders are tapped off, either direct or, in the case of long feeders, through adjustable boosting converters. With such a system the number of feeders can in most cases be considerably reduced, which means increased economy, as, for example, two No. 0000 lines cost less and give less trouble than the same amount of copper in eight No. 3 lines. Less copper, even, may be used by cross connecting the feeders, so that they may help each other out when unequally loaded.

Only a few years ago it was considered impossible to run alternators in multiple arc, or, if possible, not commercially practicable. In the year 1889 the now classical experiments of Mr. Mordey proved the contrary. In these experiments he coupled together two large alternators without resistance or impedance coils:

(1) When running at the same speeds and voltage, but regardless of phase.

(2) When running at the same speeds, but generating 1,000 and 2,000 volts respectively.

(3) Generating 1,000 and 2,000 volts as before, but switched simultaneously together and on to a heavy load.

(4) Running at somewhat different speeds.

In all cases they instantly pulled each other into synchronous speeds, and into proper voltage and phase relations, and ran together on all loads; proving absolutely the ability of at least one type of alternating dynamo (the Mordey-Brush) to run multipled under more trying conditions than do direct current machines.

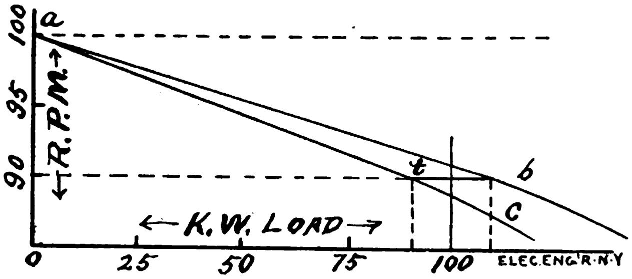

FIG. 1.

Since then the multiple method of running alternators has been generally adopted in Europe, machines of different makes and sizes being run together in some stations, and in one place (Deptford Station, London), high voltage machines being multipled with the secondaries of step-up transformers, the primaries of which are run from low voltage machines.

In this country the parallel working of alternate current machines has not as yet become prevalent. Large modern installations, such as that at Niagara, are arranged for parallel working; but the large majority of small stations work their machines entirely independently, constituting, to their own serious detriment, what Professor Fleming calls "a collection of little central stations, arranged for the sake of convenience under one roof."

The engineers of such plants have the idea that alternating dynamos must be specially made for multiple working. The best ready test of the ability of any two machines to work together is to run one of them as a synchronous motor from the other. If it holds up to speed under a complete range of loads without excessive current passing (and most good machines of the same frequency will do so) the two will run together as dynamos if properly driven. This condition as to the mode of driving is more exacting than with direct current machines; as two alternators, when switched together, must keep the same speed with as great a mathematical accuracy as though their armatures were keyed to the same shaft. Working with this premise and the nature of particular types of driving machinery, the writer has derived the treatments described below which seem to work well in practice.

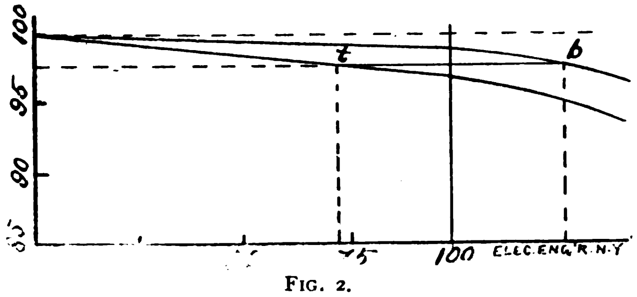

FIG. 2.

Three cases present themselves in common American usage, viz., multipling two machines:

(1) Where both are driven by the same engine or countershaft.

(2) Driven by separate engines, there being no other loads on either of those engines.

(3) Driven by separate engines, one or both of which supplies power to other loads.

In the last case no attempt had better be made to multiple the alternators, unless they constitute almost the entire engine loads, or unless the other loads on the two engines are also multipled, as for example two 500-volt generators running in parallel. The treatment becomes then the same as under case (2).

In the first case, that is where the two generators are driven from the same source of power by separate belts, the essential features for a proper division of the load are, first, such a diameter of the belt pulleys as to give both dynamos the same frequency when running light; and, second, such an arrangement that the slip of one belt shall be the same as that of the other at any load. If the condition does not comply with these requirements, the dynamo, the belt of which slips the more, will shirk its work as the load rises, making the other machine do more than its just share. In direct current working, differences in belt slip are very simply remedied by increasing the field excitation of the machine with the greater slip, thus making it take up its share of the load; but with the alternator this does no good, but makes things worse, if anything. If the two machines synchronize exactly when light, and one belt slips as much on fifty kilowatts as the other does on one hundred kilowatts, the first machine will take only one-half as much load as the second, when in parallel, no matter what tinkering is done with the fields, the armature circuits, or the load. If the fields of the shirking machine are strengthened, the machines are thrown out of phase with each other, though not out of synchronism. This generates idle currents in series through the two machines, which heat up the armatures and reduce their capacity for carrying external loads.

This running out of phase by means of idle currents makes the indications of the machine ammeters very deceiving, as under certain conditions the machine showing the greater current may be doing the lesser work, and a machine may be even motoring, that is, taking power from the other machine by wire and returning it via the belts, without showing it on the ammeter. For this reason an indicating (not a recording) wattmeter should be used on each machine in addition to the machine ammeter.

This description of the effect of the slip shows that a turn or two of the belt tighteners should have a much more beneficial effect in adjusting the relative loads between the machines than any amount of manipulation of the field rheostats; and shows also why a clean belt should be run with more slack than an oily one, etc., in multiple work. The same theory probably explains also why more success has been attained in Europe than here in such work, owing to the use there of rope driving; since rope drives with automatic tighteners are more like each other in their slippage than are belts, which vary with age, quality of leather, amount of oil, water, dressing, etc. By the same reasoning leather link belts should run better in such service than solid belting, because the comparative tension of two link belts can be more readily estimated by the eye than can that of two solid belts. Whether this is or is not the case is unknown to the writer.

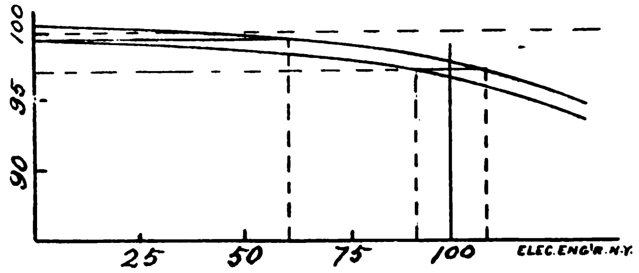

FIG. 3.

All that has been said about belts must be understood to apply only where the machines are driven from the same source of mechanical power. In the second case specified above, where separate prime movers drive the two generators, the treatment is quite different. Here the governors of the driving engines play a vitally important part. Not only must the engines drive the dynamos at the same frequency with great precision when light, but the drop in frequency must be the same in both dynamos at any load, that is, the drop due to the governing of one engine, plus the slip of its belt, must equal at any load the drop and slip of the other at the same load. If this is the case when the machines are independently run, they will divide the loads equally when run in parallel, whether of the same or different make, style and type. If this is not the case, the loads will not be equally divided, no matter what is done with the field rheostats or any other part of the electrical circuits.

It is true that the relative currents of the two machines may be varied by changing the field excitation; but the division of the load, as shown by indicating wattmeters, is not materially changed thereby, until the field excitations are unbalanced sufficiently to break the synchronism. This is owing to the fact that the relative loads depend solely on the relative cut-offs of the two units when running at the same speed.

In running two units of different sizes together, their governors should be so arranged as to slow them both down the same percentage at any proportional part of their respective rated loads. For example, in arranging a 100-kilowatt and a 500-kilowatt generator for parallel running, the governing drop in the first should be the same with a load of 25-kilowatt as in the second with 125-kilowatt, also as much in the first with 50-kilowatt as in the second with 250, and so on. Under this condition and only under this condition will the two units in multiple divide their loads properly. If the smaller unit is belt connected and the larger direct connected, the slip of the belt must be added to the governing drop of the former before the comparison is made.

Strange as it may seem, the more poorly the governors work, in the sense of slowing down as the load increases, the more uniform becomes the distribution of the loads. This may be realized by plotting together the speed regulation curves of two engines, assuming a small unavoidable difference in speed. Fig. 1 is such a diagram for a pair of direct connected alternating steam dynamos of the same size. It may be seen that they run at the same speed (100 revs.) when light, but regulate poorly and somewhat differently, a b being the curve of one machine and and a c that of the other. When the machines are independently loaded with 100 kilowatts each, the curves show that the first loses about 9 per cent. of its speed, and the second about 11 per cent.

Fig. 2 assumes the use of two governors with the same equality at zero load and the same difference at high loads, but shows better regulation for both governors; the drop of one with 100 kilowatts being 1 per cent. and that of the other 3 per cent.

Let us assume that the two machines represented in Fig. 1 are multipled with each other, also the pair in Fig. 2 with each other. Assume a load of 200 kilowatts to be applied to each pair of units. In the case of Fig. 1 it is apparent that the two machines run at the same speed (about 90 revs.) when carrying respectively about 90 and 110 kilowatts, the intersections (t and b) of the horizontal 90-rev. line being, respectively, at those loads. As the speeds of the machines must be exactly the same when in multiple, and as the kilowatt power exerted by either unit depends solely on the position of its governor, the 200 kilowatts will be divided between the generators in that proportion.

The action of a governor, as far as the relation of the point of cut-off to the speed is concerned, is of course the same, whether its dynamo is independent or multipled. In the case of Fig. 2, with better regulation, the diagram shows that the two engines run synchronously when delivering, respectively, about 70 and 130 kilowatts. This gives obviously a poorer distribution because of the better regulation. A little inspection of the figures will show that the multipling of one of the machines represented in Fig. 1, with either of those represented in Fig. 2 would give a much worse load division, the latter machine doing almost all the work at any load.

In Fig. 3 is shown the case of two governors that do not quite run together at any load, the regulation curves being similar but differing from each other for all loads by about one per ent. While the work will be divided fairly well at high loads, as is shown by a speed of 97 revolutions for 92 and 108 kilowatts, respectively, one engine will cut-off at the very beginning of the stroke while the other is carrying 60 kilowatts. The first engine then acts as a brake and its dynamo as a motor. If the internal losses of the engine and dynamo are 12 killowatts, the slower will absorb this amount from the faster and the output from the pair will be 48 kilowatts. With atmospheric exhaust and some valve mechanisms the engine cylinder becomes an air-pump as the cut-off approaches zero of the stroke, absorbing a large amount of power. This explains why, as has been found, some machines run well together when loaded, but get into trouble when light.

The phenomena illustrated in these figures are modified somewhat when belt driven units are used instead of direct connected units. The modification is caused by the slip of the belts, which, being approximately proportional to the load, virtually increases the downward inclination of the regulation curves, since these curves are intended to express the speed regulation at the dynamo shaft. In accordance with the theory given above, belt driven alternators should therefore multiple better than direct driven, other things remaining the same.

AMERICAN ELECTRICAL APPARATUS IN SIAM.

A dispatch of April 10 from Bangkok, Siam, says: The Siamese government granted to Mr. Bennett, an American citizen, one of the greatest concessions ever given by Siam, viz.: a franchise for the exclusive electric lighting of Bangkok. This is attributed to Minister Barrett's diplomatic settlement of the recent trouble, and is noteworthy as a further development of American interests in Asia.

SOCIETY & CLUB NOTES

FIFTH ANNUAL DINNER N. Y. ELECTRICAL CONTRACTORS' ASSOCIATION.

THE fifth annual dinner of the New York Electrical Contractors' Asso'n. was held on April 21, at 8 p. m., at the Hotel Flouret, Fifth avenue, New York City. The gathering was a large and representative one, at least 100 being present, while the arrangements were admirably carried out by the dinner committee, Messrs. C. L. Eidlitz, J. C. Hatzel and J. T. Hunt, and the reception committee, J. R. Strong, E. S. Keefer, P. H. Klein, Jr., J. P. Hall and W. W. Ames. The dinner was given in a handsomely decorated room and was well served. Mr. J. T. Hunt acted as toastmaster in a very easy and graceful manner, and made a forcible claim as to the value and importance of the work being done by contractors and their co-laborers in various parts of the electrical field. He called upon President J. C. Hatzel to respond to the toast of the association.

MR. HATZEL said: It seems fitting and appropriate on this occasion to give a brief résumé of the history of this association, and what it has accomplished. The majority of the gentlemen present are identified more or less directly with the electrical interests and incidentally with ours, in fact, to a great extent our interests are mutual. This mutual interest, in a financial way, naturally applies more directly to the gentlemen who furnish us our material and supplies, but it applies also, if only as a mere matter of sentiment to our friends, the consulting engineers, who share largely in the credit if their plans and specifications are carried out by the contractor to a satisfactory conclusion and who also share largely in the general condemnation if (so to speak) "things don't jibe."

It applies to the inspection departments of the Fire Underwriters and fire department, who can be saved considerable labor and stationery, in advising us of violations, if we consider our interests mutual. It applies to the illuminating companies, who benefit us by prompt and efficient service for our customers, and are benefited by us in turn, as by our zeal to secure business, we secure them new customers and in any controversy over bills, assure them of the correctness and infallibility of the meters. And last, but not least, it applies to the technical press. It would be superfluous if not arrogant to attempt to define this interest on our part, and we can only retaliate by stating that did not the electrical interests exist, there would be no necessity for the existence of the technical electrical press.

In the belief that your identity with the electrical interests may interest you in our association a brief history of its origin, past history and what it has accomplished may be of benefit to all. In the summer of 1892, directly after the great strike in the structural iron business, several members of this association now present received a communication from the United Building Trades (a council composed of delegates representing employers in the building industry), suggesting the advisability of forming an association of electrical contractors and having this association represented in this council. This suggestion was evidently due to the fact that ours was about the only industry in the building trades which had no organization, and the desire to have all trades organized and represented in the United Building Trades, to enable employers by united and concerted action to prevent strikes and adjust labor difficulties. Adopting the suggestion of this communication, this association was organized, and it is a pleasure to state, that the charter members, with one exception, are members to-day.

The first two years of our existence were devoted almost exclusively to the adjustment of labor difficulties, which were sufficiently numerous and harassing to prevent consideration of other objects for which the association was formed. In that time, however, the members had become thoroughly acquainted with one another and it is with pleasure and pride that I testify to the devotion of the members to one another in time of trouble, and to the self-sacrifice often made necessary by these labor troubles. Lifelong friendships were formed and the bitter personalities formerly indulged in and induced by keen competition were no longer heard. The belief of every individual contractor that he was the only competent and responsible party to successfully undertake and complete an installation was badly shaken, when by association he found he was not "the only pebble on the beach," but "that there were others."

While this association numerically and financially may represent a smaller percentage of the United Building Trades than a number of others, it has gained the admiration of all by its uncompromising, determined and united stand against all odds when positive it was in the right. This has been particularly noticeable in our labor troubles, when the trouble of one was the concern of all.

It may be stated without fear of contradiction, that this association represents about 85 per cent. of the work performed in our industry in the metropolitan district and naturally their action influences the trade generally. On this supposition we have endeavored in the past few years, during our respite from labor troubles to advance the profession, placing it on a higher plane and incidentally improve our finances. With this object in view we have endeavored with the able assistance of the consulting engineers to have proper provision made in buildings for the installation of our work, and architects generally now consider this in their plans, where formally no provision whatever was made and the electrical contractor was obliged to utilize every crack, crevice or corner that was left over after the autocratic plumber, steam, gas and water fitter got through.

We are recognized in the formulating of new rules pertaining to our work, and this is especially true of the fire department, to whom we are greatly indebted through the courtesy of the superintendent and chief inspector of the inspection department. We have established the most friendly relations with the illuminating companies. Our relations with the manufacturers are most cordial, and we hope in the near future to induce all of them to establish a trade price and a price for customers whom they sell direct. Ours appears to be the only trade where such a condition does not exist.

MR. E. H. JOHNSON replied to the toast of "Our Guests," after an enthusiastic reception, and went into an interesting and favorable review of American interior work as compared with much of that done abroad. He also pointed to the drift of the times in requiring an electrical contractor to do all the electrical work in any new building, with an undivided responsibility. This tendency was already pronounced and would dominate entirely in the next few years.

MR. A. HENDERSON replied to the toast of the Fire Department, as Chief Inspector of the Bureau of Electrical Inspection, and spoke of the good results of the one and a half years of work. Inspection carefully carried out now kept the work done in the New York district in the lead by a large majority. Mr. Henderson amused his auditors with some good stories.

MR. ANDERSON spoke in behalf of the New York Board of Fire Underwriters, and approved the co-operation of all interests to insure perfect construction. He knew that electrical work was sometimes defective but gas installation was more so, in spite of its long practice. Mr. Anderson was warmly received, but admitted he was out against the doctor's orders.

MR. J. W. LIEB, JR., responded for the "Illuminating Companies" and described vividly the crude conditions of early supply of current, from central stations, the first Edison plant in New York having neither voltmeter nor ammeter. With the advance in central station work had gone a higher standard of wiring construction with great advantage all around.

MR. C. O. MAILLOUX responded on behalf of "The Electrical Engineers," and elicited much laughter by complaining that he had not been furnished with plans and specifications for his speech. As a consulting engineer, he went on to enunciate some admirable ideas of the relation of that body of men to the contracting engineers, and particularly in regard to their responsibility to the purchaser of the apparatus and installation.

MR. T. C. MARTIN replied for "The Technical Press." He said that a short time ago a boy had applied at one of the city free libraries for a book on "How to Get Educated and How to Stay So." The electrical contractors had no doubt educated themselves thoroughly by reading all the books available on the subject of electricity, but he ventured to think they could not stay educated unless they studied with painstaking regularity the pages of the electrical press.

MR. J. W. GODFREY brought the oratory of the evening to a bright and happy close by treating the toast of "Our Creditors" in a very cheerful manner, indicative of the high esteem had by wire makers and other dealers in apparatus of all kinds for the general solvency and solid financial repute of the electrical contractors as a body. He concluded with a poetic tribute of admiration, which brought down the house, and which told how the contractor coming into this world naked and bare, worried through it in such a way as to earn the love of everybody and a cool place in the future life.

After Mr. Godfrey's poetical fireworks had shot off their last sprays of color and sparkle, a small stage at one end of the hall was occupied by a number of artists engaged for the occasion, including such celebrities as "Press" Eldridge, Tom Ballantine, Horace Golden and Messrs. Cooper, Miller and Le Monier. Somewhere between 2:30 and 4:30 the company separated, and saluted in parting the brilliant monogram of the association in frosted lamps over the portals of the hotel. Some of the guests on invitation of Mr. Blizard took a ride in the electric horseless vehicles, which, owing to the clearness of the streets were able to "let themselves loose."

THE OMAHA TECHNICAL CLUB.

On April 8 there was organized at Omaha, Neb., the Technical Club of Omaha, 69 engineers, architects and others interested in engineering work, having for its object the advancement of the profession in general. The following officers were elected: George H. Pegram, M. Am. Soc. C. E., chief engineer Union Pacific Railway system, president; George T. Prince, M. Am. Soc. C. E., chief engineer Omaha Water Company, vice-president; Harry Lawrie, architect, secretary; Curtis C. Turner, C. E., treasurer; Andrew Rosewater, M. Am. Soc. C. E., director for two years; Edward F. Schurig, electrical engineer, city electrician, director for three years.

Thirty-five persons were present and sixty-five have signified their intention to join the club. Meetings will be held on the third Monday of each month, except July and August.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Secretary George F. Porter, who has just returned from a consultation at Niagara Falls with President Nicholls, informs us that arrangements have been made with the management of the International Hotel and Cataract House, Niagara Falls, to take care of members and delegates of the National Electric Light Association attending their twentieth convention, June 8, 9, 10. Rates range from $3 to $5 per day, American plan.

The headquarters and convention hall will be at the International Hotel. Floor plans of both houses can be seen at headquarters of the association, 136 Liberty street, New York, where reservation of rooms can be made. Mr. Porter says that there are signs of an extraordinarily large attendance and that the interest in the convention is very general.

MUNICIPAL PLANTS.

At the University of Wisconsin, Madison, Wis., on April 3, the Engineers' Association had a discussion with the U. W. Engineers' Club on the question whether it is desirable for the city of Madison to have its own electric light plant. The question was decided in the negative.

EDUCATIONAL

UNIVERSITY OF NEBRASKA.

At the University of Nebraska, Lincoln, Neb., Mr. E. G. Willyoung, of Philadelphia, will begin on April 26 a course of lectures on "Electrical Measuring Instruments," being part of the series lately organized by Prof. R. B. Owens for bringing his students in touch with the practical side of things.

The Nebraska Legislature, before adjourning, gave the University $30,000 for the wing of a new engineering building. The edifice will be laid out for extensions, and on a plan involving a total final expenditure of about $80,000.

PERSONAL

MR. H. C. GUNTON and Mr. H. Lomas, two English electrical engineers from Manchester, have recently been making an extensive trip through the country as far West as Chicago, examining electric light and electric railway work. They left for England by the Campania on Saturday last, well pleased with their trip and with what they had seen.

MR. W. R. CARSON has become superintendent of the Eddy Electric Motor Company's factory at Windsor, Conn., vice Mr. G. T. Briggs, who is to take charge of the Briggs Manufacturing Company, at Voluntown. Mr. L. L. Rivers becomes assistant superintendent. Both of them have been some time with the Eddy Company.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 20, 1897.

Alarms and Signals:—

FIRE-ALARM SYSTEM. C. E. Buell, North Plainfield, N. J., 580,927. Filed April 29, 1894.

Comprises a circuit controller that is held to close a circuit by a fusible substance, and when acted upon by heat opens the circuit and then closes it.

SWITCH AND SIGNAL APPARATUS. C. A. Geissenhainer, Pittsburg, Pa, 580,973. Filed May 25, 1896.

Comprises a longitudinally movable rod, and electric motor for operating the rod, a sliding trigger, a pendant arm engaged by the trigger, and electrical connections between the trigger and motor.

Batteries, Secondary:

CONSTRUCTION OF BATTERIES. E. N. Dickerson, New York, 581,104. Filed March 28, 1892.

A caseless battery, the elements with the aid of gaskets forming the cells.

Connectors, Conduits and Insulators:—

SECTION INSULATOR FOR ELECTRIC RAILWAYS. S. L. Foster, San Francisco, Cal., 581,023. Filed December 23, 1896.

Details of construction.

JUNCTION BOX COUPLING FOR ELECTRIC WIRE CONDUITS. J. P. Cochlin, Worcester, Mass., 581,064. Filed February 8, 1897.

Embodies a coupling for attaching the conduit thereto, consisting of a hollow coupling bushing exteriorly screw-threaded, and interiorly smooth.

ELECTRIC WIRE INSULATOR. J. E. Sharpe, Oneida, N. Y., 581,088. Filed February 8, 1897.

Consists of a block of non-conducting material provided with parallel wire-receiving grooves, respectively, in its top and bottom, and with channels at opposite sides of and at right angles to the grooves, for the reception of fastening devices.

ERECTING AERIAL ELECTRIC CABLES. F. S. Viele, Pittsburg, Pa., 581,242. Filed November 12, 1896.

Employs a curved rail and clamps adapted to secure the ends of the rail in line with the messenger wire.

Dynamos and Motors:—

ARMATURE FOR DYNAMO ELECTRIC MACHINES. A. L. Parcelle, Boston, Mass., 580,889. Filed October 9, 1893.

Comprises a laminated core, a supporting frame provided with arms which engage the periphery of the core, and enter grooves therein to keep the core permanent, and means for keeping the laminæ of the core in place.

SECTIONAL ARMATURE FOR DYNAMO AND ELECTRIC MOTORS. G. L. Jeck, Nashville, Tenn., 580,977. Filed January 9, 1897.

Comprises a series of interchangeable shuttle sections, wound with wire of different gauge and resistance, so that by removing one series of sections and replacing another series the machine may be changed from a dynamo to a motor.

DYNAMO ELECTRIC MACHINE. M. O. Southworth, Indianapolis, Ind., 581,089. Filed September 22, 1896.

A casting embodying a set of shoes for dynamo electric machines, united by webs and provided with lugs whereby they may be secured to the face plate of a turning machine and be finished altogether before separation.

Electro-Metallurgy:—

APPARATUS FOR SEPARATING PRECIOUS METALS FROM METALLIC ORES. C. F. Pike, Philadelphia, Pa., 581,032. Filed April 6, 1894.

Employs a body of mercury upon which ore is placed, an intermittently acting electro magnet above the body of mercury, and electric circuits in which the magnets are situated.

PROCESS OF AND APPARATUS FOR SEPARATING PRECIOUS METALS FROM MAGNETIC ORES. C. F. Pike, Philadelphia, Pa., 581,034. Filed October 21, 1896.

Means for the separation of gold from what is known as "black sand," a comminuted magnetic ore in which fine particles of gold are loosely held.

MAGNET. G. G. Brown, Brooklyn, N. Y., 581,101. Filed April 7, 1896.

Adapted for use in ore separators.

PROCESS OF TREATING ORES CONTAINING SILVER AND GOLD. H. Hirsching, Salt Lake City, Utah, 581,160. Filed August 9, 1895.

Consists in subjecting copper in the presence of moisture to the action of ammonia and a nitrate, and then decomposing the resulting solution to separately recover therefrom the metal and the ammonia.

Electro Therapeutics:

ELECTRO-MEDICAL APPARATUS. R. H. Wappler, New York, 581,091. Filed February 5, 1897.

Means to regulate the current.

Lamps and Appurtenances:—

OSCILLATING INTERRUPTER. D. McF. Moore, Newark, N. J., 580,987. Filed December 3, 1895.

The combination of an oscillating member capable of vibration in different planes, of a ring or encircling contact member. Intended for vacuum tube lighting.

INTERRUPTER. D. McF. Moore, Newark, N. J., 580,998. Filed December 3, 1895.

Consists in operating the interrupter by an electro-magnet traversed by an alternating current passing over a circuit independent of that controlled by that of the interrupter contacts.

ELECTRIC LIGHT AND HEAD GEAR FOR SURGICAL USE. L. Woolf, New York, 581,052. Filed December 30, 1896.

Details of construction.

ELECTRIC ARC LAMP. W. L. Preece, Derby, Eng., 581,136. Filed July 7, 1896.

A frictional grip which allows a sliding rod to be freely moved in one direction, but holds it firmly when strained in the opposite direction unless it be released.

Miscellaneous:—

ELECTRIC SELLING DEVICE. A. Davidson, New York, and C. G. Armstrong, Chicago, Ill., 580,931. Filed January 25, 1896.

A device to permit of the sale of reserved seat tickets, at a number of different stations in such a manner as to prevent the sale of the same ticket at two different stations.

APPARATUS FOR BLEACHING BY ELECTROLYSIS. A. E. Woolf, New York, 581,052. Filed Dec. 30, 1896.

For bleaching textile fabric thread, wood-pulp, or other material by the electrolysis of a saline solution or a solution of a chlorid of salt.

ELECTRICAL RESISTANCE COIL. J. Nebel, London, Eng., 581,170. Filed June 12, 1895.

Comprises casing of heat conducting material, a resistance coil supported therein, and insulating granular material within the tube and surrounding the coil.

APPARATUS FOR UTILIZING ROENTGEN RAYS. C. F. Easton, Wallace, Idaho, 581,199. Filed June 1, 1896.

Consists of a case which is opaque to X-rays, a Crookes tube, arranged within it, a vertically adjustable arm supporting the tube, and means for adjusting the arm horizontally and laterally.

ELECTRIC PUMP. B. Heftye, Tuxpan, Mexico, 581,204. Filed October 10, 1896.

The pump, cylinders and pistons constitute an electro-magnetic engine.

METHOD OF AND APPARATUS FOR DISINFECTING AND DEODORIZING. A. E. Woolf, New York, 580,919. Filed April 19, 1894.

Consists in discharging or injecting into a stream of infected water or sewage, an electrolyzed solution of salt water.

Switches, Cut-Outs, Etc.:—

INTERLOCKING SWITCH FOR THEATRE DIMMERS. G. L. Colgate, Westfield, N. J., 580,929. Filed November 16, 1896.

Means for the regulation of lights of different parts of a theatre.

AUTOMATIC CUT-OUT. C. A. Rolfe, Chicago, Ill., 580,957. Filed July 16, 1896.

Means to shunt the cut-out when the current becomes greater than the safety of the instrument will warrant.

Telegraphs:—

TELEGRAPH KEY. M. M. Porter, Malone, N. Y., 581,135. Filed May 13, 1896.

Means for automatically closing the circuit through the instrument after the key shall have been released by an operator.

Telephones:—

MAGNETO TELEPHONE. L. E. Dye, Morris, Minn., 580,851. Filed May 27, 1896.

Details of construction.

TELEPHONE SWITCHBOARD. C. E. Egan, Chicago, Ill., 580,853. Filed December 5, 1896.

Comprises a stationary jack, a pair of movable arms with their front ends projecting in front of the board in proximity to the jack, and contact points in the path of the arms, one contact point being in the circuit of the signaling apparatus, and the other in the telephone circuit.

ANNUNCIATOR SIGNAL FOR TELEPHONE SYSTEMS. W. F. Smith, San Francisco, Cal., 581,044. Filed August 4, 1894.

Means for signaling the operator and registering at the station switchboard the number of the telephone with which the subscriber desires to connect his telephone.

COMBINED TELEPHONE AND ELECTRIC LIGHTING SYSTEM. C. E. Buell, North Plainfield, N. J., 581,246. Filed July 27, 1896.

Means whereby a system of lines that are used for electric lighting, can be utilized for the transmission of conversation.

REPORTS OF COMPANIES

STANDARD AIR-BRAKE CO.

The annual meeting of the stockholders of the Standard Air-Brake Company was held at the company's office, 100 Broadway, New York, Wednesday the 21st. The following directors were elected to serve for the ensuing year: Henry Seligman, Edward J. Wessels, Albert Strauss, Leopold Wallach, Theodore Seligman and D. F. Meyer.

The engineering staff of the Standard Air-Brake Company has been increased by the addition of Mr. Edward H. Dewson, Jr., with whom General Manager Wessels lately closed a contract for a term of years. Mr. Dewson brings to the company a ripe experience. He entered upon his new field April 26. Mr. Dewson has been long and favorably known in connection with his work while with the General Electric Company in their engineering department and in connection with locomotive practice and the superintendency of one of the Western lines. He has for some time filled the position of master mechanic for the Pratt & Letchworth Company, of Buffalo. Mr. Dewson is thoroughly posted on the mechanical arts and will find full scope for his ability in his new field.

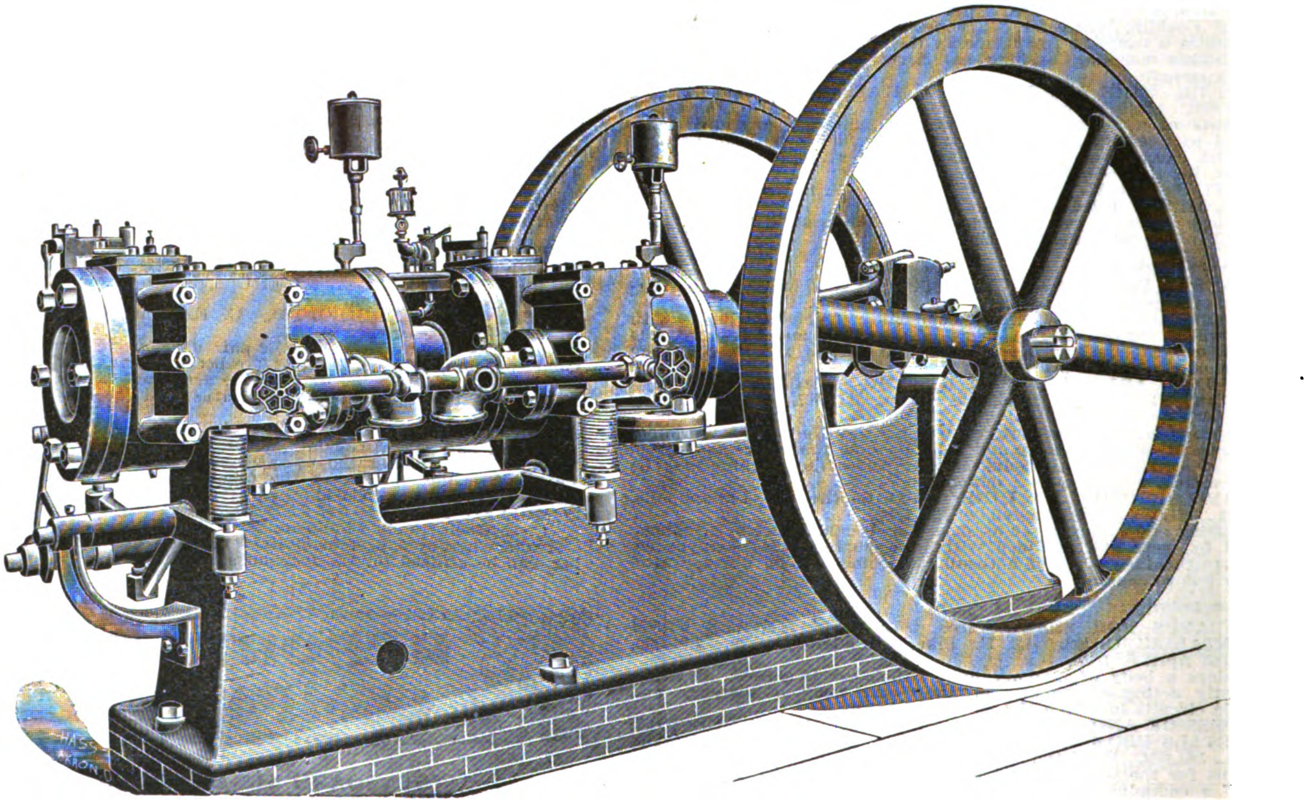
THE NEW YORK HEAT, LIGHT AND POWER COMPANY is now controlled under lease by Messrs. Oscar T. Crosby and C. A. Lieb.

TRADE NOTES & NOVELTIES

THE HICKS SELF-STARTING GAS AND GASOLINE ENGINES FOR ELECTRIC LIGHTING.

It is well known that a given amount of illuminating gas or gasoline burned in the cylinder of a gas engine will produce nearly twice as much illumination in candle power than when burned in gas burners. Hence we find the gas engine making rapid strides in isolated plant lighting and for the charging of storage batteries. When to this is added the absence of boiler, with its attendant nuisance of hauling coal and and ashes, the convenience of a gas engine which can be started up at a moment's notice, becomes aparent.

In seeking to utilize these advantages the Yaryan Company, 142 Times Building, New York, have placed on the market the Hicks self-starting gas and gasoline engine, a view of which is given in the accompanying engraving. In this engine two cylinders set in line are employed to work alternately, their pistons being on one piston rod, to which an effective impulse is imparted for every revolution of the crank, doubling the power of the engine while adding only the weight of one cylinder and piston, a very small percentage of the whole weight of the engine. By this doubling the number of effective strokes of the piston a very much steadier motion is attained.



The Hicks Self-Starting Gas and Gasolene Engine.

The operation of the engine is as follows: Under 15 horse power, which are not self-starting, the gas throttle valve being opened, the fly-wheel is turned by hand once or twice, and the engine starts in full operation. At the first outward movement of the piston the explosive compound is drawn into one of the cylinders, say the end one, through the valves, which then close and prevent its flowing back into the pipe as the pistons make their back stroke. While the compound in the end cylinder is being compressed in the end of the cylinder, the crank shaft passes its in-center, the charge in the end cylinder is exploded and the expanding air and gases drive the piston out rapidly and start the engine. When the piston has completed its outward movement and starts back, the escape valve is opened and the burnt gases in the cylinder allowed to escape. On its next outward movement, the piston again draws in a fresh charge of the compound which is compressed and exploded as before. When the pistons are on the outward stroke under the impulse of the explosion in the end cylinder, the front cylinder is drawing in its charge of the compound to be compressed and exploded, while the end cylinder is being cleared of the burnt gases and recharged, the two cylinders thus working alternately.

It will be seen that many advantages arise from this construction and arrangement of the parts. Every out stroke of the piston delivers power to the shaft so that the engine is twice as powerful as one in which every other out stroke, only, is a power stroke; and further, all the power of the piston tends to force the shaft on to the solid parts of its bearing, and thus relieves the cap entirely of wear. In fact, the cap might be entirely removed and the engine would run, consequently there will be no jumping or pounding of the shaft in any of the bearings. The valves admitting the compound to the cylinders are direct acting vertical poppet valves, and being always closed on their seats when combustion is going on, they remain perfectly clean and require no attention or occasional scraping. The governor regulates the engine to a nicety as with steam. The engine is so well balanced that it can be run at full speed without being fastened down to the floor or foundation.

FESSENDEN MFG. CO.

The Fessenden Manufacturing Company is organized under the laws of the State of Pennsylvania. The capital stock of the company is $100,000, and the directors are D. N. Seely, F. H. Seely, J. G. Wainwright, J. F. Tener, N. L. Tener. The company has been formed for the purpose of manufacturing under the patents of Prof. Reginald A. Fessenden, and the apparatus which it now has ready for the market are the Shadowless Arc Lamp and X-Ray outfit. The latter apparatus was illustrated and described by us last week. The arc lamp is striking in that it casts absolutely no shadow, and that it is only 12 inches long when furnished with the shortest style of globe. The lamp can be entirely enclosed within the holophane, and many handsome and peculiar forms of globe can be used. The life without inner mantle is 50 hours, and with the mantle from 100 to 150 hours. Mr. J. F. Tener is manager of the new company, which has headquarters at Pittsburg, with branch offices at room No. 307, Electrical Exchange, New York, and room 780 Monon Building, Chicago.

THE EDDY ELECTRIC MANUFACTURING COMPANY, Windsor, Conn., are now represented on the Pacific coast by the California Electrical Works, San Francisco.

NEW C. & C. IRON CLAD MOTOR.

THE C & C Electric Motor Company, of New York, have just brought out a series of ironclad motors of the type shown in the accompanying engravings, which possess a number of very desirable features.

The frame consists of a soft steel shell with radial poles projecting inwardly; the shell is capped at each end with a circular end plate, which carries the bearings and also the rocker arm support.

The machine has four poles and magnet coils, and the coils may be readily removed after taking out the armature, and are interchangeable.

The armature, of drum type, is built up of thin laminae of soft iron, well insulated to provide against Foucault currents, and having the conductors laid in slots, the coils being wound on forms.

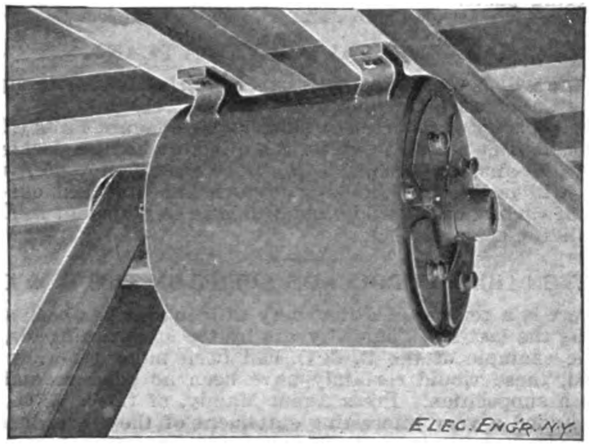


Fig. 1.—C & C Iron Clad Motor.

The commutator is of generous proportions with ample brush surface, and the brush pin support is designed to secure mechanical rigidity and to avoid humming noises.

The brush holders are of the well-known C. & C. reaction type, securing a flexible and even pressure of the brushes with a minimum wear, and of such design that the brushes maintain a constant relative position on the commutator, thereby providing against the necessity of shifting the brushes forward when they have been shortened by wear.

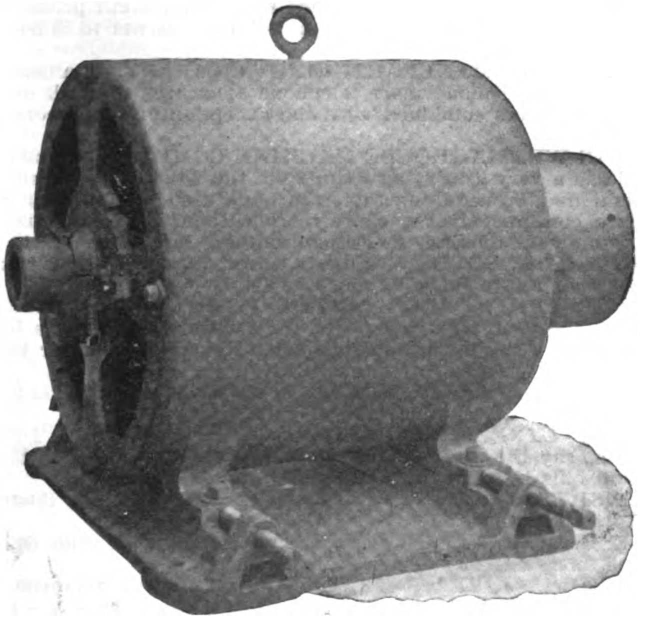

Fig. 2.—C & C Iron Clad Motor.

The bearings are self-oiling, with oil wells of large capacity, thus providing an ample quantity of clear oil for lubricating purposes. The shaft is of best steel and of such proportions as to insure rigidity and ample driving capacity.

The cylindrical form of the machine makes it well adapted to all cases of direct connection, either through gears or otherwise. The gear shaft boxes can be placed on the shell at any convenient position, as the distance from the shaft to the outside of the shell is always the same. The machine itself can be placed in any horizontal position, thus making it well adapted to run as a ceiling motor, or attached at any angle to an "A" frame, or to bolt on the bed plate of any machine or tool with which it may be combined; the circular form of the end plates allowing them to be bolted on always with the oil wells in the proper position.

The ironclad magnetic field is ideal in its compactness, its circuits of minimum length and its freedom from external field or magnetic leakage; all of which qualities effect a saving in magnetic force, and consequently a gain in efficiency. While improving on the ordinary type by providing an ironclad type of field, the outer shell also forms a protection to the motor, making it especially valuable where dust or dirt or dampness are apt to occur, and, in fact, anywhere where employés are liable to be careless with the motor. It will also be noted that the commutator is inside of the shell, thereby gaining full protection. Indeed none of the moving parts, except the pulley, pinion or coupling, are outside of the shell, which secures safety not only to the operator, but also to the armature of the machine.

As the shell is of steel ⅝ inch or more thick, it may be tapped into wherever desirable, as in a case of direct application to machine tools or other classes of machinery, providing iron bolts are used, thus making the motor form part of the frame work as well as the driving power.

The construction of the armature, while making it a beautiful winding, has also the mechanical advantage that it can be handled without danger to the winding, the conductors being below the surface of the armature.

The efficiency of the C & C ironclad motors ranges from 85 to 92 per cent., depending on the size of the motor.

The construction of these motors is such that they can be belted, back-geared, direct connected or furnished with change gears to drive at a range of speeds.

G. E. MAGNETIC BLOWOUT LIGHTING ARRESTER FOR RAILWAY CIRCUITS.

IN order that lightning arresters may be effective in conducting away high potential discharges generated in overhead lines by atmospheric disturbance, they must have less resistance across the spark gaps than the apparatus to be protected. Railway armatures are usually constructed with insulation that will stand a high potential test of approximately 3,000 volts, and very often lightning arresters are used that require from 8,000 to 10,000 volts for the current to pass across the gap spaces in them. It is easily seen that arresters having long gap spaces are likely to fail to protect electrical machinery.

In the new arrester for 500 volts continuous current work, known as type M-D, recently designed by the General Electric Company, and illustrated in the accompanying engravings, the spark gap which separates the overhead line connection from the ground connection is only one thirty-second of an inch and 2,000 volts only are required for the electric current to bridge this gap. After the passage of the high voltage current, if there were no means of rupturing the arc, a short circuit would be maintained and the lightning arrester would be completely destroyed. In this arrester, the gap is placed in a strong magnetic field, which tends to force the arc from the field and ruptures the current. It is the same principle em-

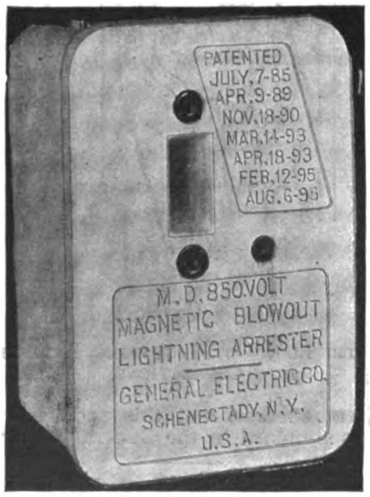

Fig. 1.—Magnetic Blow-Out Lightning Arrester, Closed.

ployed for rupturing arcs in circuit breakers and car controllers.

In order to limit the current, a low non-inductive resistance is placed in circuit. The spark gaps are mounted on the cover and may be easily removed from the circuit for inspection and adjustment. In the station type all the metal parts are contained within a substantial porcelain box. For line use, the arrester is placed in an iron case or wooden box.

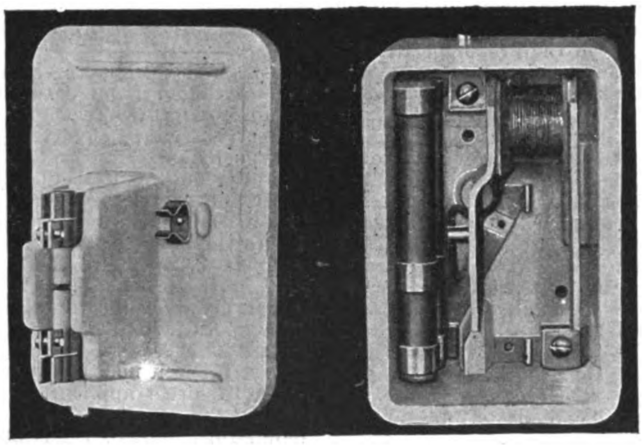

FIG. 2.—MAGNETIC BLOW-OUT LIGHTNING ARRESTER, OPEN.

Arresters of similar type have been used for the past two years with great success, and this perfected type has now been adopted as standard by the General Electric Company.

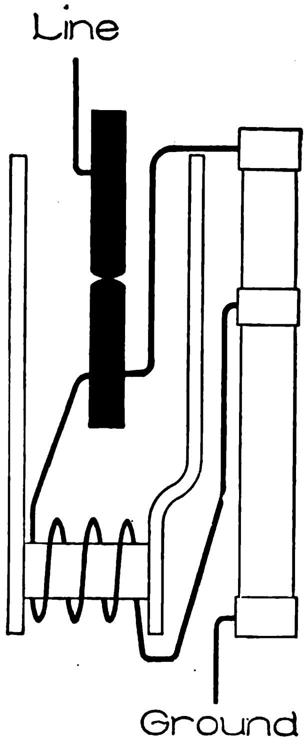

FIG. 3.—MAGNETIC BLOW-OUT LIGHTNING ARRESTER, DIAGRAM OF CONNECTIONS.

HIGHLAND INSULATING SOLDERING PASTE.

Soldering fluid made from zinc cut with muriatic acid, as is well known, is harmful to insulation. The zinc chloride it contains will not only decompose the insulation, but will continue indefinitely to absorb moisture. Again, the fluid being thin, the workman invariably uses an excess, which runs down into the commutator, or between the wires of the armature or other apparatus, and often causes a ground or short circuit.

To meet this want of a safe and rapid soldering compound, the Highland Electro Chemical Manufacturing Company, of Connellsville, Pa., are manufacturing the "Highland" insulating soldering paste.

The material itself is an insulator; it can be more quickly applied and is cleaner than a fluid. It contains absolutely no acid; being in a paste form it cannot be spilt or splashed on the work. In a deep joint as on a commutator, a small amount will run at once, when the iron is applied, into every crevice of the joint. In soldering copper wire a streak of it like a grease mark will do the work. It will not run where it is not wanted, as the cold part of the commutator, for example, will chill an excess. If it is not used in excess, no fumes will be given off. It is also claimed to be the cheapest compound to use. It is concentrated, and a little goes a long way, as it cannot be spilt or wasted.

The company have many valuable letters from leading electrical manufacturers attesting the merits of the Highland soldering paste.

CANADIAN CARBORUNDUM PLANT.

Work will be begun at once by the Carborundum Company on its Canadian plant across the river.

The capacity of the present plant in the Niagara Falls (N. Y.) power district will be doubled, the directors having decided to make the amount 2,000 e. h. p., twice the amount used now. This will enable the company to turn out four and one-half tons of carborundum a day and will give employment to about 25 additional men.

SEVEN MILLION DOLLARS SPENT ON THE B. & O.

There is a general idea that very little money has been spent during the last few "panic" years by the steam railroads, but if the example of the B. & O. had been more generally followed, there would certainly have been no good ground for such a supposition. Press Agent Maddy, of the B. & O., has just issued a very interesting statement of the work done on the road since February, 1896. The expenditure figures up $7,000,000, and this amount does not include the outlay for 58,000 tons of 85-pound steel rail just ordered, costing about $1,000,000 more. Probably the B. & O. was never in better physical condition than to-day or better able to compete for local and through traffic wherever its lines run.

ADVERTISERS' HINTS

WARD-LEONARD ELECTRIC COMPANY, Hoboken, N. J., are offering ventilating fan speed regulators at cut prices for all sizes and kinds of motors from 1-12 horse-power to 25 horse-power.

VIADUCT MANUFACTURING COMPANY, Baltimore, claim to have made more telephone apparatus than all other manufacturers combined with the exception of the American Bell Co.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, publish a very gratifying letter from the Bristol (Pa.) Electric Light and Power Company, who have used one of their engines continuously for eight years without its costing them anything for repairs. They have nothing but praise for it.

HENRY F. NOYES, 56 Liberty street, New York, advertises "How to Apply for a Patent," at $1.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., have an iron roof which they will dispose of at a bargain. It is admirably adapted for a machine shop, car barn or general manufacturing purposes.

NATIONAL TUBE WORKS COMPANY advertise trolley poles.

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., say they can save customers 25 to 50 per cent. on their lamp bills by renewing burned-out lamps.

FISHER & CRAMPHORN, Congress and A streets, Boston, show another style of their station switches.

E. G. BERNARD COMPANY, Troy, N. Y., have some dynamos for sale at prices worth investigating.

SCHIFF, JORDAN & CO., New York, have removed to larger quarters at 232 Greenwich street, where they are better than ever able to make prompt shipments of carbons for all kinds of arc lamps.

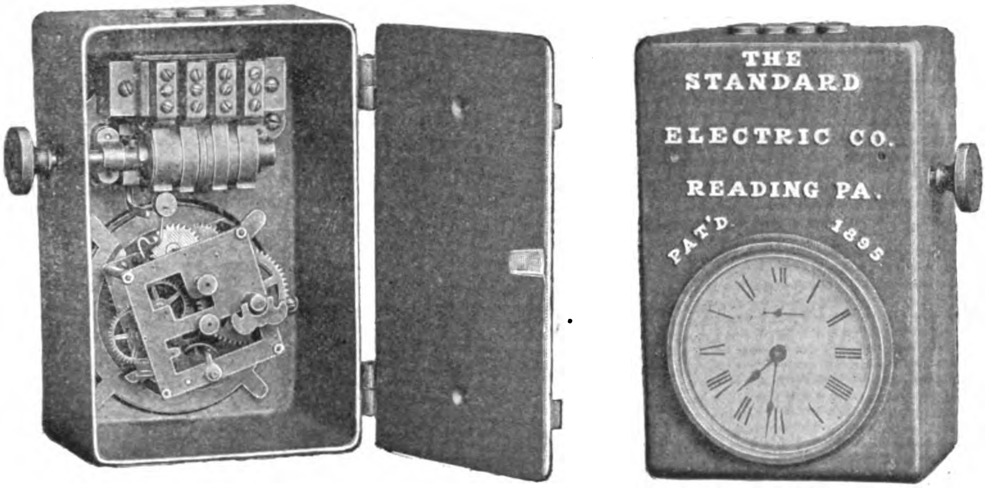
HART & HEGEMAN, Hartford, Conn., illustrate their "ad" with a cut of their No. 2 box for iron armored conduit with gang of two switches which they furnish with any number of outlets desired.

MR. A. C. DARRAGH, general manager of the Purity Filter Company, 211 Water street, Pittsburg, Pa., has issued for 1897 a neat little brochure with catechism on oil filtration and giving a number of testimonials. He says: "We are well satisfied that we fly the pennant as to sales and satisfaction."

THE STANDARD AUTOMATIC TIME CUT-OUT.

EVER since the introduction of incandescent lamps devices have been constructed for cutting off current automatically. In most cases this was accomplished by the use of magnets, which in course of time proved unreliable and caused their abandonment.

The Standard automatic time cut-out, illustrated in the accompanying engravings, is a device purely mechanical and well calculated to meet all requirements and any demand made upon it up to its carrying capacity. For display windows the merchant will find it invaluable as a saver of current and most convenient for cutting off current at any given time.



THE STANDARD AUTOMATIC TIME CUT OUT.

By means of this switch the consumer is saved the annoyance and inconvenience of going himself or sending another person to the point of consumption in order to break the circuit. On account of the inconvenience of this proceeding, it is seldom done, and the consumer who has his lamps longer in circuit than he needs them, is saved this unnecessary expense.

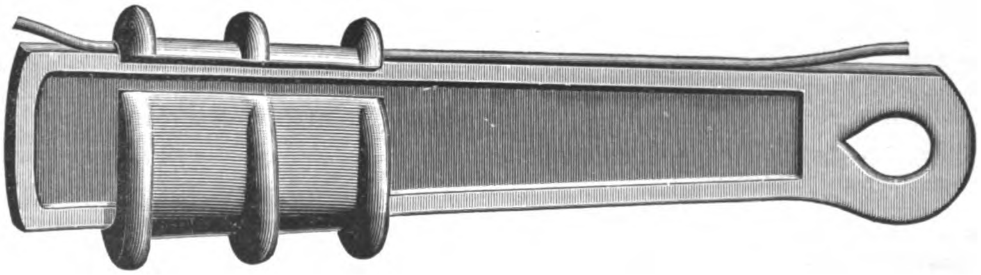
With the Standard automatic time switch in circuit, the consumer has merely to wind the clock work and to set the "let-off" mechanism, so that it will be released at the desired time; he can then turn on the switch and leave the device to operate automatically. If, however, it is desired to switch off the current before the time determined upon, and perhaps to again complete the circuit, or if it be found desirable to turn on the switch and to turn it off again after the time switch has operated automatically, all this can be done without any interference with the automatic mechanism employed in the switch.

The Standard cut-out has been approved by the Fire Underwriters for currents up to 40 amperes and 220 volts. It is made double-pole, but can be wired so as to make it a single pole device as well.

The Standard automatic cut-out is manufactured by the Standard Electric Company, of Reading, Pa., for whom Mr. R. E. Difenderfer, of 20 North Fifth street, Philadelphia, is general agent.

THE CLEVELAND "COME ALONG" WIRE STRETCHER.

WE illustrate herewith a quite novel wire stretcher or "come-along," which will be of interest to every construction man. It is called the "Cleveland" come-along, and consists of only two pieces of malleable iron. It does away with all springs, screws, eccentrics, etc., yet is claimed to be the most positive in clamping and easiest to release of any clamp heretofore introduced. It is made in two sizes, the No. 1 for wires of a larger gauge than No. 8, and the No. 2 for No. 8 wire or smaller wires. The illustration shows the No. 2, but the principle is the same in both sizes.



THE CLEVELAND "COME ALONG" WIRE STRETCHER.

The "come-along" consists of a wedge-shaped piece having an eye at its smaller end for attaching the rope. This wedge-shaped piece slides in a flattened tapering sleeve, having an opening to one side to admit the wire; the edge of the wedge-shaped piece next the opening in sleeve, is grooved to fit the wire and is parallel to the adjacent wall of sleeve so that as the wedged-shaped piece is drawn towards the small end of the tapering sleeve the wire is clamped the whole length of the sleeve and held positively as long as the tension is maintained. On releasing the tension and giving the sleeve a slight blow at the small end the clamp is instantly released.

These come-alongs are made with copper faces for use with hard drawn copper lines. Messrs. J. H. Bunnell & Co., 76 Cortlandt street, New York, are the sole agents.

NEW YORK NOTES.

GENERAL ELECTRIC COMPANY have received an order for several hundred alternating current induction motors, to be used to operate the Tuerk ceiling fan, manufactured by the Hunter Fan and Motor Company, of Fulton, N. Y. This is a high indorsement of the alternating current induction motor, inasmuch as hundreds of these motors were used last year for operating Tuerk ceiling fans, to the entire satisfaction of the Hunter Company.

MIDLAND ELECTRIC COMPANY, of 281 Pearl street, New York City, manufacturers of electric batteries, have gone into the hands of the sheriff. The company had a capital stock of $10,000. It has ceased to do business for a month past. The effects will be sold Thursday, April 29.

SCHIFF, JORDAN & CO., of Vienna and New York, owing to the increased demand for their well-known brand of high grade imported carbons, have taken larger and more commodious quarters at 232 Greenwich street. At this address the company will have not only its offices but a capacious warehouse in which will be stored a full line of all sizes of high grade imported carbons. Mr. Ralph Straschnow will continue the management of the company's affairs and will be pleased to see all his friends at his new address.

THE STANDARD PAINT COMPANY, F. S. De Ronde, general sales agent, 81-83 John street, New York City, inform us that they have just arranged with the Electric Appliance Company, of Chicago, to handle their P. & B. products extensively. That concern will carry a large stock at all times, and their store will be known as the Western Depot fór the P. & B. insulating compound, armature varnish, tape, etc. They are prepared to fill large orders promptly direct from stock. This method will enable Western purchasers to get their wants supplied in a speedy and convenient manner.

MICANITE IMPROVEMENTS.—The Mica Insulator Company's plant at Schenectady has been again increased by some very fine machinery for the purpose of milling their Micanite plates to more accurate thicknesses. Their insulating commutator segments are steadily gaining ground. The difficulty they at first experienced from the cement oozing out when the commutator became too hot while running has been entirely overcome. They report business greatly improved, and during the past year of depression have prepared themselves for a much larger business. At the present moment their factory in the machine department is already putting in some overtime. There is no doubt that Micanite is playing a very important part in electrical machine design and has a very bright future before it.

THE GARVIN MACHINE COMPANY, Spring and Yarick streets, New York City, have just issued a very neat and most useful illustrated catalogue and price list. It shows a bewildering variety of labor-saving machinery of latest style and construction at the lowest price consistent with good workmanship and durability.

MR. MAX OSTERBERG, of the firm of Osterberg & Sutton, succeeded recently in locating a bullet very near the spinal column of a patient in the Smith Infirmary on Staten Island. The case was one of peculiar difficulty as but a couple of small storage batteries were on hand, and the exposure had to be quick since the man was on the point of death. The negative showed not only the exact lócation of the bullet, but also the outline of the wound and that had been washed out with iodoform. The cord and the vertabrae were also plainly discernible.

MR. SAMUEL RUSSELL, JR., who has been connected with the Crocker-Wheeler Electric Company for some time past, at the Ampere factory, has now taken up their representation at the Philadelphia office, 14 South Broad street. He is thoroughly familiar with this standard apparatus, and there is no doubt that a large market exists in the territory he is now covering in conjunction with Mr. H. S. Smith.

WESTERN NOTES

MR. J. E. ELLIOTT, general manager of the National Electric Company, reports business brisk in repair line. The National Electric Company is a new concern and starts out with good prospects. Mr. Elliott is a man of long experience in electrical field and all his friends wish him well in this new enterprise.

MAXSTADT ELECTRIC FUSE COMPANY has been formed in Chicago to make electrical appliances and supplies, with a capital stock of $2,500. The incorporators are F. G. Jones, S. W. Norton, C. D. Stillwell, C. S. French and S. A. French.

THE METROPOLITAN ELECTRIC COMPANY, of Chicago, has been given the agency for the Thompson-Brown arc light hanger board. This is one of the best hanger boards on the market, is neat, well built, of good mechanical construction, and a good seller; filling all the requirements of the underwriters, and one that will meet the approval of the best electricians.

THE C. H. LEVER MFG. CO., makers of wooden specialties for electrical and other purposes, have moved their quarters from 16 North Canal street to 19-21 North Jefferson street, Chicago.

TOLEDO, O.—The Saddler automatic switch and electric signal system is to be built for electric roads by the Saddler Electric Switch and Signal Company, of Toledo, whose factory and salesroom are at 809 Monroe street, that city. Mr. C. W. Munson is secretary and treasurer.

PHILADELPHIA NOTES

MR. L. R. SCHULTZ, formerly with the Penn Electric Engineering Company, has opened offices as consulting engineer at 1001 Chestnut street. Mr. Schultz is acting as engineer for the Girard Estate, who are putting up extensive buildings on Eleventh street; and he has also several large contracts on hand.

READING, PA.—The firm of Clymer & Heilman, manufacturing electricians, has been dissolved by mutual consent, Mr. E. S. Clymer having fallen heir to a controlling interest in the East Saginaw (Mich.) Electric Light Company, to which plant he will devote his personal attention, while Mr. D. B. Heilman has accepted a position as general superintendent for the Standard Electric Company, of Reading, who are manufacturing time cut-outs, fan motors, quick break switches and other electrical apparatus.

THE CATHOLIC PROTECTORY, Valley Forge, Pa., for whom Wilson Bros., Drexel Building, Philadelphia, are the architects and engineers, will be entirely equipped with electric motive power for the propulsion of machinery intended for use by 2,000 boys, who will be engaged in learning shoemaking, printing, book-binding, blacksmithing and tailoring under instructions from technical experts employed by the order of Christian Brothers.

The Electrical Engineer.

Vol. XXIII. MAY 5, 1897. No. 470.

POWER TRANSMISSION

ELECTRICITY IN COAL MINING.

BY HARRY N. GARDNER.

A GOOD example of the economical results of applying electricity to mining purposes is to be found in the anthracite mines of the New York and Scranton Coal Company, located at Peckville, Pa., about eight miles from the city of Scranton.

The two mines of this company, the Ontario and Sturges, are located well up on the mountain side above the town. They are about three-quarters of a mile apart, the Ontario being what is termed a "slope" or tunnel mine, while the Sturges is entered by a shaft about two hundred feet in depth. There is but one breaker, located some distance below the entrance to the Ontario.

A double inclined cable road is used to lower the coal from the Ontario mine to the head of the breaker, a loaded trip of cars in its descent always pulling back a trip of "empties" upon the other track. Two donkey engines are used in the transportation of coal from the Sturgess shaft to the breaker, and to handle the culm upon the dump.

AN ANTHRACITE COAL BREAKER.

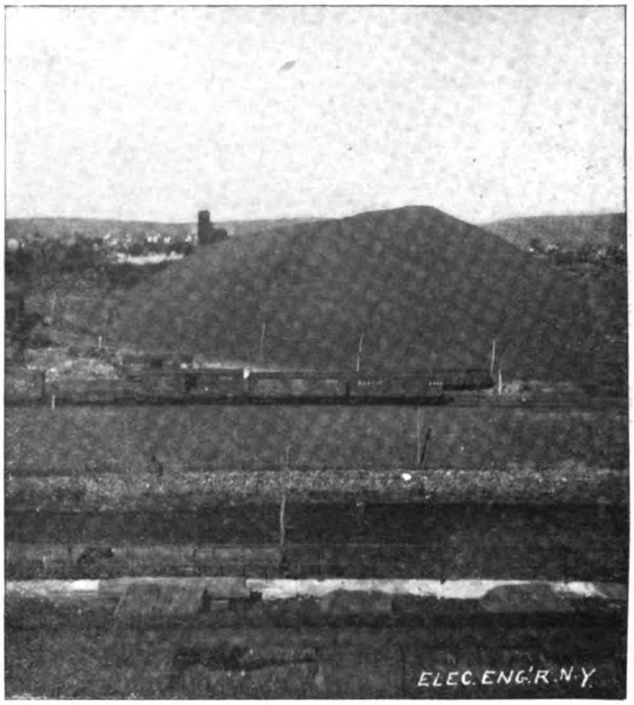
Two electrical plants assist in the operation of these mines. The generating machinery for the Sturges mine is in the building at the head of the shaft which contains the engines and drums for operating the shaft carriages. One building is also used near the entrance to the Ontario mine to contain the electrical generating machinery and the engines and cable drum for the gravity cable way. Thus one engineer at each place can look after the entire plant.

For the electrical plant at the Sturges shaft a 60-horse-power Ball & Wood engine is used. The engine is belt-connected to an old type bipolar 40-kilowatt C & C generator, operating at 250 volts.

The No. 0000 cable leads are carried beneath the floor to the skeleton oak switchboard, standing a few feet from the dynamo. The switchboard contains the regular instruments, ampere and voltmeters, a G. E. blow-out circuit breaker, large main switch, rheostat and lamps.

Both sides of the circuit lead from the switchboard and out of the building to the head of the shaft a few feet distant. No. 0000 solid wire is used, and the mains are carried down the side of the shaft upon glass insulators, the wooden bracket supports being fastened to the shaft timbers. A lightning arrester protects the line at its exit from the power house, and another arrester is placed in the mine at the foot of the shaft.

Besides the branch circuit taken off for the power house lights, another branch circuit leads from the switchboard to a smaller switchboard in an adjoining room. In this room is a four-pole General Electric 7½-horse-power dynamo, which is used to furnish power for the pump line when the large generator is not running. This dynamo is driven from the main shaft that operates the ventilating fan. When the large generator is running, power for the pump line is taken from the main circuit. But it is sometimes unnecessary to run the large dynamo, because it frequently happens that the mines are in operation but three or four days a week. The pump, however, must be kept running; and when the large generator is idle the small one is started and switched onto the pump circuit.



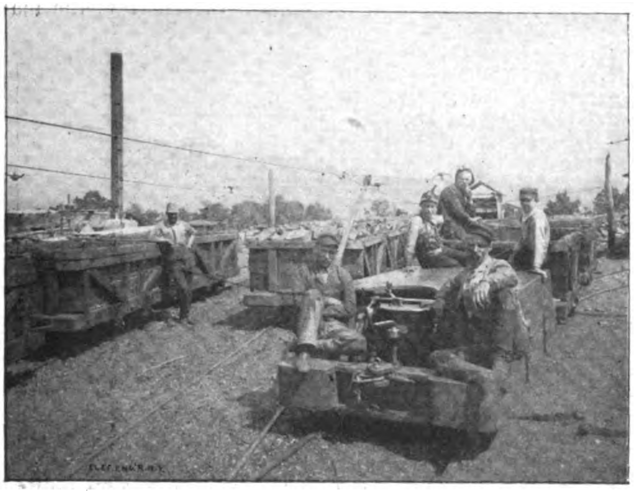
AN ANTHRACITE CULM DUMP.

ELEC.ENG'R.N.Y.

ELECTRIC DRILL IN COAL MINE.

At the foot of the shaft one side of the circuit is attached to the rails, and wherever the locomotive is used in the mine, the rails are bonded with a single bond of No. 0 copper wire.

The No. 0000 feeder runs from the foot of the shaft some distance into the mine, being supported at the side of the mine upon wooden brackets and glass insulators. The feeder is tapped into the trolley line at three points, a single pole switch being used to cut in the current at these places. As the three sections of trolley are insulated from each other, it is thus possible to cut out any section if desired for any purpose.



Electric Motor at Ontario Tunnel, Scranton, Pa.

The trolley wire is No. 0 hard drawn copper, and is supported by wooden blocks bolted to the roof of the mine. To fasten these blocks, holes are drilled in the roof, into which the bolts holding them are secured by means of split pipe wedges. The old type of General Electric clamping ears and hangers are used to support the wires and insulate them from the blocks. Instead of being placed overhead midway between the tracks, where it would be in the way of the men and mules, the trolley wire is suspended at one side at a point about six inches outside the rail.

As the hangers are attached directly to the blocks upon the roof, and the mine varies from five to eight feet in height, the trolley pole spring is kept in operation more constantly than upon street railroads. On account of the angle at which the trolley pole stands to the wire, and because of the varying height of the wire, an ordinary trolley wheel attachment could not be kept upon the wire if any speed was maintained. The trolley wheel for mine use is therefore connected to the pole with a swivel attachment. On account of the location of the wire, the trolley pole is, of course, attached to one corner instead of the center of the locomotive.

The locomotive used is a regular General Electric 6½-ton mine locomotive, driven by two W. P. 30 motors. As these locomotives are only three feet in height, it is possible to operate them in low roof mines where it would be impossible to use mules for haulage without going to the expense of blowing down part of the rock roof for headway.

The locomotive is used only in the main tunnels, mules still being used to draw the cars from the chambers and the main gangway. At present the locomotive runs from the shaft to a point about 4,000 feet distant. At the farther end of the trolley line a grade of three per cent. against the load extends for some distance. Up this it would tax two mules to draw a loaded car. In order that the locomotive may not be overloaded because of the voltage drop at the end of the line, only two loaded cars are handled by it on this grade. This load is increased to eight or ten cars upon the more level stretches nearer the foot of the shaft, where the voltage drop is less.

Not only does the locomotive handle from two to three times the load which a team of mules would draw, but it handles it from two to three times as fast. There are no mules to get in the way of one another, nor any conflict of loaded trips going out and "empties" coming in. It is therefore found that one locomotive with two men to operate it, can perform the work of from ten to fourteen mules and the necessary driver boys.

When the locomotive is not in use it is housed in a side chamber near the foot of the shaft. This chamber contains a repair pit, so that the under part of the motor can be conveniently gotten at.

The wires for the pump circuit run down the shaft the same as the trolley feeders, two No. 6 wires being used for this purpose. From the foot of the shaft the wires are conducted to the point where the pump is now located, about 4,200 feet distant, upon porcelain knobs, placed upon the side of the mine near the roof. To fasten these knobs, holes were simply "drilled and plugged" in the mine wall, the knobs being screwed fast to the plugs. If a steam pump were used in such a place the steam piping would be more expensive than the wire, it would require more work to change the location of the pump, and more care would be necessary to attend to its operation.

The mine was not in operation the day when it was recently visited; but Mr. W. M. Price, the efficient electrician for the company, descended the shaft, and gave the writer an underground trolley ride. When the end of the line was reached, there was the five horse-power bipolar C & C motor working away energetically at its pump. There it works day in and day out, the only attention it requires being to start it and an occasional oiling. A 5 by 6 inch vertical triplex pump is used; and the motor and pump are mounted upon a truck so that they can be easily moved from place to place.

At the foot of the shaft, and at important points along the main gangway, incandescent lights are tapped off from the trolley circuit. All the underground lights, as well as those in the power house are run three in series.

The plant at the Ontario tunnel consists of a 12 by 16-inch McEwen engine, which develops 90 horse-power, belt connected to a General Electric 55 kilowatt four-pole, steel frame generator. Weston volt and amperemeters, Carpenter rheostat, blowout circuit breaker, and the switches, mounted upon a skeleton switchboard complete the station equipment.

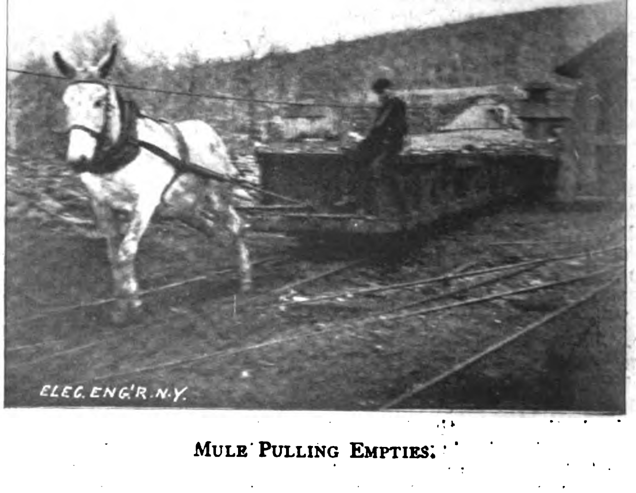
But one lightning arrester is used, that at the exit of the lines from the power house. The same voltage is used as in the Sturges mine.

As the locomotive in this case draws the cars to the tunnel's mouth, it is also used outside of the mine to do the necessary switching. When not in use it is housed in a small building a short distance from the tunnel. The locomotive is similar to one in the other mine, and the same trolley construction is used; but as it enters less than half as far as in the other mine, no feeder wire enters the tunnel.

A drill circuit of No. 6 wire is tapped off from the trolley some distance in the tunnel, and from there it is led through a side chamber to another part of the mine. Two drills are used. Each of these, with their motor, which will develop 3 horse-power for short periods, weighs but 121 pounds. The motors are entirely inclosed; thus the drills will stand the rough handling to which they are subjected in being dragged from one part of the mine to another. Current is taken from the stationary wires to whatever part of a chamber a drill happens to be working in by means of a flexible cable. The motor runs at 1,600 revolutions, and a nine to one reducing gear is used for the drill.

With one of these drills two men can drive a six-foot hole, changing drills in the operation, in five minutes; while three or four times that, and much harder labor would be required to drive the same hole by hand.

No better idea of the financial side of these electric plants can be given than to quote from a paper read before the Anthracite Coal Operators' Association in January of this year, by Frederick J. Platt, the engineer who installed these plants.



Mule Pulling Empties.

In one part of his paper he said:

"I will now take up two electric haulage plants at the mines of the New York & Scranton Coal Company, at Peckville, Pa., based on the expenses of the year 1896.

"Sturges shaft plant consists of an engine and dynamo, one 6½ ton locomotive and 4,500 feet of trolley wire. Cost, $6,103. Five per cent. depreciation per year would amount to $305.15, or for 200 working days, $1.52 per day.

"Cost of operating is as follows:

Motorman	$1.75
Helper	1.25
Electrician	.78
Repairs	1.03
Depreciation	1.52
Oil	.24
Total	$6.57

showing a cost by electric haulage for 250 tons of 2.62 cents per ton.

"By mule power the cost would be:

14 mules @ 50 cents	$7.00
7 boys @ $1.35	9.45
Total	$16.45

"or a cost for 250 tons of 6.58 cents per ton. Thus showing a saving of 3.96 cents per ton, or for 250 tons, about $9.90 per day. Taking 200 working days in the year, there is a saving of $1,980. The locomotive travels about 32 miles per day and has run about 7,800 miles, with a cost for repairs of 2.7 cents per mile.

"This company has also an electric haulage plant at its tunnel opening, where the cost is as follows:

Cost of plant $7,039.00
5 per cent. depreciation .... $351.95, or $1.75 per day

Cost of electric haulage:

Motorman	$1.75
Helper	1.25
Electrician	.78
Repairs	.65
5 per cent. depreciation	1.75
Oil	.24
Total	$6.42

Cost of electric haulage for 600 tons, 1.7 cents.

Cost of mule haulage:

12 mules @ 50 cents	$6.00
6 boys @ $1.35	8.10
Total	$14.10

"Cost of mule haulage for 600 tons, 2.35 cents, or a saving of 1.28 cents per ton.

"Saving on 600 tons, $7.68 per day.

"Saving in year of 200 working days, $1,536."

Of the electric pump in the Sturges mine he said:

"Comparing it with a steam pump for the same work, we find that it is saving the cost of two men or boys, who would be required to look after a steam pump, from the fact that the pump is first running on water and then on air, and a steam pump under these conditions would require close watching.

"Had a steam pump been used in this place it would have been necessary to put down a bore hole for the exhaust steam, or use a surface condenser, as the roof in a return airway is very poor, and would not permit the exhaust steam being turned into it.

"This pump and the wiring cost $625, which was less than a steam pump with the piping. The repairs during 1896, including wire used in changing its location, amounted to $159.55 for 365 days and nights.

"The cost of operating per day of 24 hours, for the past year, has been as follows:

Repairs	$0.43
Oil	.10
Electrician	.41
Total	$.94

"Cost of operating a steam pump would have been at least two boys @ $1.25—$2.50, without taking into account the oil and repairs. The saving therefore has been at least $1.56. It has run for 970 days, which shows a total saving of $1,513.

"The fact that the pump is drawing water through 700 feet of suction pipe is one of the strong points in favor of electric over steam pumps for such work as pumping out dips and slopes which are being driven, as it only becomes necessary to change the location of an electric pump every few months, instead of every few weeks, as would be necessary were a steam pump used."

In speaking of electric drills he referred to one of those in the Ontario mine when he said:

"The New York & Scranton Coal Co. is using one of these drills for driving a heading and airway through a poor piece of coal. The vein averages 7 feet 5 inches in height and contains 46 inches of coal and 43 inches of rock. It is driving this at a cost of $2.85 per yard, as against $5 per yard, hand work. In the month of September it drove 109 yards; 58 yards in the heading and 51 yards in the airway, which was a decidedly good showing for an electric drill as compared to what could have been done by hand power, both as regards to cost and number of feet driven.

"In all of the above figures you are probably aware that no charge has been made for steam used by the generating plant. This is due to the fact that in none of the above mentioned cases has it been necessary to add to the boiler plant, and the fuel used practically costs the company nothing."

In regard to the economy of electric haulage in coal mining, the superintendent of the Hillside Coal and Iron Company, which at Forest City, Pa., operate the largest electric mining plant in the United States, recently said that he had kept an account of the cost of operating one part of a certain mine with mules and another part of the same mine with an electric locomotive. He had figured his mules as costing only 25 cents a day each; but he admitted that he had given the mules the benefit of every doubt.

With mule haulage he found that it cost 5.86 cents per ton, while the electric locomotive did the work for 5.04 cents a ton. "This looks like a rather small saving, only .82 of a cent a ton, or only 14 per cent. in the cost of haulage," said the superintendent, "but it is only fair to explain that the electric locomotive worked in a part of the mine where mules could not be used on account of the steepness of the grade against the load, while the slight grade in the part of the mine operated by mules, is in favor of the load."

ELECTRIC LIGHTING

ARC LIGHTING IN AMERICA AND EUROPE.[1]

BY C. WILER.

In America arc lighting was considered a necessity while it was a luxury in Europe. It is no wonder then that the streets of American cities and towns have been glittering in the splendor of the electric light while Europeans were still content with gas and oil and thus too it became possible that the keen foresight and genius developed in our country a system which allowed of an economical distribution over a large area and left nothing to be desired as regards simplicity.

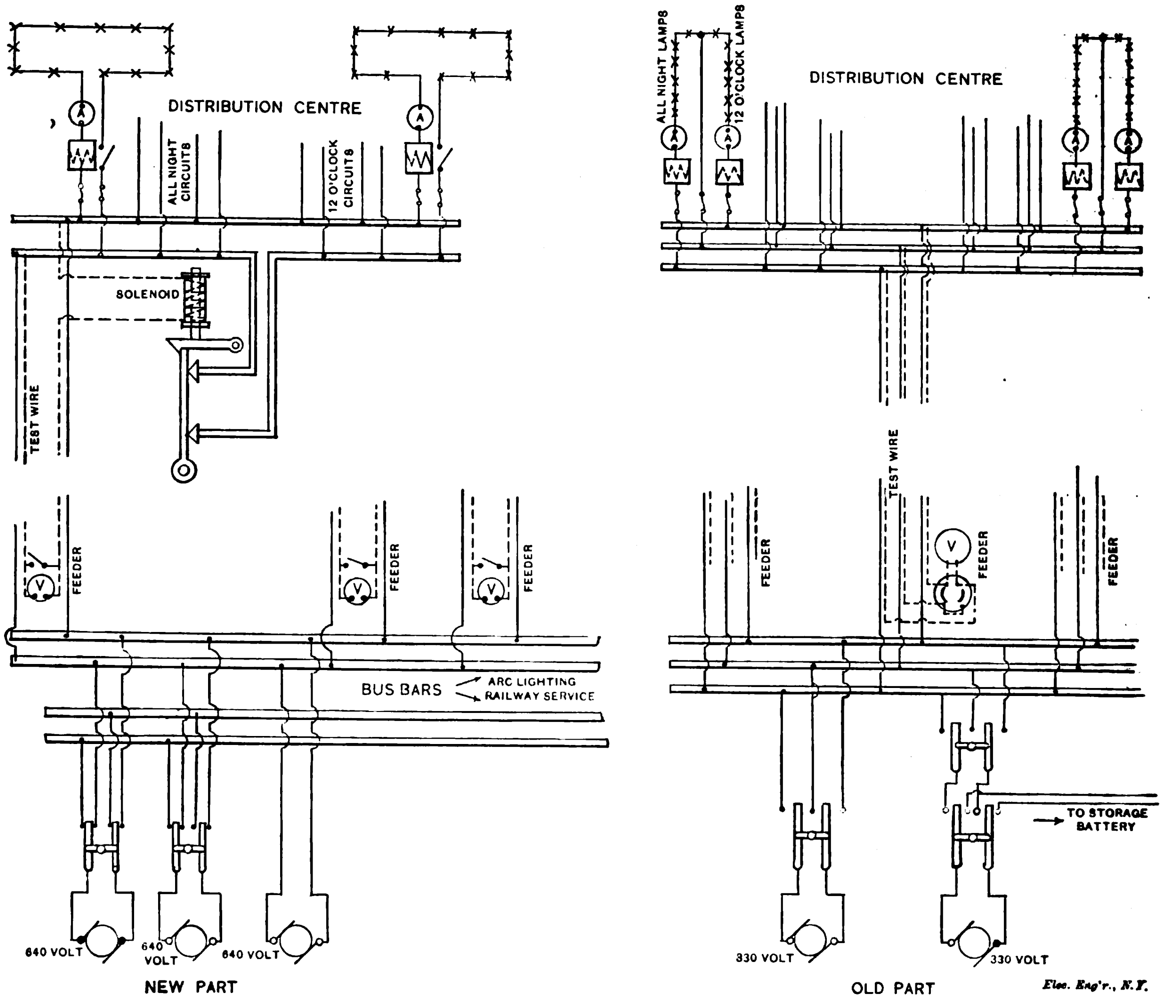
Series arc lighting with constant current dynamos of varying electromotive force found its birthplace, its application and its perfection in America. Up to date it has hardly gained a foothold on the European continent. It was adopted in England at the time that the Brush and Thomson-Houston machines made their first appearance and although the plants are still running and a few have been added, the system has been nearly entirely abandoned. The desire to supply arc and incandescent light as well as the motive power from one and the same generator, the once low efficiency of arc dynamos, the use of small high-speed units, the consequently inferior arrangement of the steam plant, and, last, but not least, the high pressure for interior lighting are the objections made abroad against high tension series arc lighting. Some of these objections have of late years been overcome in our land since larger units were built. The speed of arc dynamos has been decreased and hand in hand therewith their efficiency has been increased, so that to-day the commercial efficiency of a 60-light dynamo reaches 82 to 83 per cent. and of a 100-light about 86 per cent. Since, however, the speed has been decreased to about 800 revolutions per minute for 60-light dynamos, and to about 500 to 600 r. p. m. for 100-light dynamos, it has been made possible to escape that labyrinth of countershafts, belts, pulleys, clutches and bearings which for many years was characteristic of an arc plant. This enabled an economical arrangement of the steam plant. The countershaft can be avoided, as arc dynamos can be direct connected with the steam engine.

Series arc lighting predominates in America. Arc lighting by constant potential circuits was developed much later than in Europe. It has come into extensive use here since 1891, especially in large cities for private lighting. Most of the large direct current supply stations for light and motive power here and abroad use the three-wire system with 220 volts across the outers, in Germany in conjunction with storage batteries. Plants, which serve mainly for arc lighting on the European continent, use the two-wire system with a pressure from 110 to 650 volts. The turning on or off of public street lamps, which are connected with constantly supplied circuits is mostly done by hand when the area covered is small. When the supply extends over a large area, street lamps are turned on or off from the station or the distribution point. Each circuit with from 2 to 12 lamps in series is controlled from the station switchboard or from the distribution center, where the necessary measuring instruments for each circuit (ammeter, voltmeter, polarity indicator) and rheostats are placed.

---

[1] Abstract of a paper read before the Chicago Elec. Assn., April 16.

Figs. 1, 2, 3 and 4 (modified from the Elektrotechnische Zeitschrift) show the arrangement made in the combined arc and railway plants of the city of Munich. The voltage of the generators is 640, 12 lamps are connected in series in one circuit. The feeders are run to well designed distribution centers which are located on the street and resemble patrol boxes in their exterior appearance. From here the arc circuits branch out. The all-night circuits are connected with the same side of the bus bars in the distribution center as the incoming feeder, while the 12 o'clock circuits are connected with the other side. Both sides can be disconnected by an automatic cut-out, the fine wire winding of which is connected with a test wire which indicates in the station the voltage of the feeder end. But short-circuiting the voltmeter in the station the current rises sufficiently to operate the automatic cut-out, which disconnects the desired circuits.



Elec. Eng'r., N.Y.

FIGS. 1, 2, 3 AND 4.—COMBINED ARC AND RAILWAY POWER CIRCUIT ARRANGEMENTS, MUNICH, GERMANY.

In the old part of the plant the three-wire system is used for the feeders as well as for the arc circuits. The all-night lamps are placed on one side of the neutral, the midnight lights on the other. The three-wire system is changed into a two-wire system after midnight; the disconnected dynamo can be used for the charging of a storage battery during the rest of the night.

Thus far only direct current distribution systems have been considered. Alternating arc lighting has been kept in the background both here and abroad. Only within a few years has it come into a more extensive use, especially in the European continental countries, where it is no longer regarded as much inferior to direct current lighting. The success is to some extent due to moderate frequencies, to the use of the very best proper size, and even special carbons and to the prevailing tendency of using lamps with a very fine adjustment and slow feed.

Alternating street lamps are connected in America with an individual transformer, the secondary voltage of which is 30 to 40, the primary mostly 1,000 or 2,000. This does not require a great amount of wire, allows an economical distribution over a large area, makes the lamps independent of each other and avoids a complicated lamp mechanism. It has the drawback of requiring a special transformer for each lamp. When alternating arc lamps are connected with incandescent circuits the lamp voltage is obtained either by the introduction of sufficient resistance, by a transformer or by a choking coil, usually called an economy coil. The coils are wound either for 50 volt circuits for the connection of one or two lamps or for 100 to 110 volt circuits for the connection of one to three lamps. Some are arranged so that the lamps can be turned on or off independently of each other.

Since the Frankfort exposition in 1891 a large number of alternating current stations have been built on the European continent. Some of the older ones, as Cologne and Amsterdam, supply each consumer with an individual transformer, the secondary voltage is 72. An intermediate terminal on the transformer allows of the use of single lamps at 36 volts. Most of the stations built later connect the lamps with a network of secondary mains fed from a transformer substation. The voltage is 110 or 120, so that three lamps can be connected in series with a suitable choking coil, which takes the place of the ohmic resistance of the direct current lamp. Quite recently the Avenue de l'Opera in Paris has been again lighted with alternating current lamps. The first attempt was made in 1878 with Jablochkoff candles, but since 1882 the street had been lighted with gas. The primary current is stepped down to 220 volts. Two transformers are used, each supplying five circuits. Five lamps are connected in series on one circuit, requiring $5 \times 36 = 180$ volts, the choking coil for five lamps requires 20 volts; a drop of 20 volts in the line is allowed, which makes a total of 220. After midnight the illumination is reduced by disconnecting the transformer from the 12 o'clock circuits.

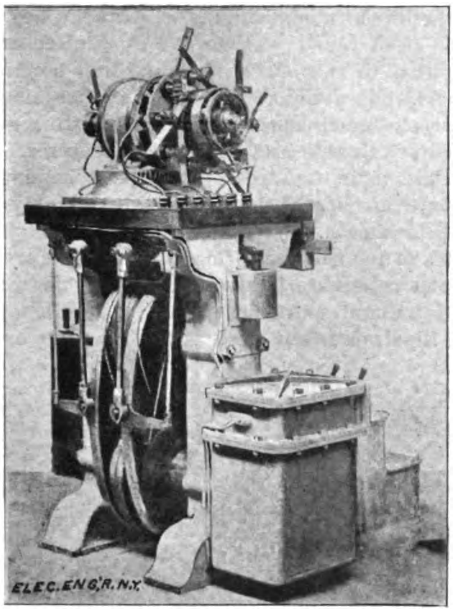


Fig. 5.—Ferranti Rectifier for Arc Light Current.

These examples serve to show that alternating arc lighting is in vogue on the European continent. Various attempts have been made to run a large number of alternating arc lamps in series from a constant current dynamo with varying voltage or they have been connected with a constant current transformer; other methods for alternating series arc lighting have been proposed and tried, none, however, have come into extensive use. The difficulties in high series alternating lighting arise in the lamps which are not yet satisfactory. They have been overcome in England by rectifying the negative waves of the alternating current. The current from the constant potential alternator is led to a constant current transformer. This consists of moveable primary coils and fixed secondaries; the force of repulsion between primary and secondary is balanced by adjustable weights. The regulation is dependent upon the leakage in the transformer. The current is brought from the converter to the rectifier proper, which is a revolving commutator driven by a synchronous motor. The pulsating direct current is sent from here into the line. The crater is formed at the positive carbon, the light is consequently thrown downwards, just as in a direct current lamp.

A rectifier set requires but small floor space and very little attendance. The wear of the brushes on the commutator is said to be not worse than on arc machines. The efficiency of a 40-light set is about 81 per cent. The rectifier system fills a long-felt want in England as is amply demonstrated by its rapid introduction. Fig. 5 shows the latest type of Ferranti rectifier; it has a capacity of 50 12-ampere lamps. These are the systems which at present are used in America and Europe for the distribution of electrical energy for arc lighting.

In taking up the final conversion into light we will compare European with American lamps. Gravity feed is nowadays used everywhere, the mechanical means for accomplishing the feed, however, differ greatly from one another. The clutch and rod is the American standard, the clutch or brake wheel in connection with a gear and a rack rod, the English. The rack, the chain or ribbon in connection with a train of wheels is the standard on the continent of Europe. The arc in American lamps is mostly traveling. The interior of the globe, the lower carbon holder and the lamp rod are not protected against the weather. With these concessions a greater simplicity has been obtained than in foreign lamps which are mostly of the focusing type and encased.

English lamps are very simple in construction, those of the other European countires, however, show strongly the hand of the clockmaker. They are often fitted with contrivances which are easily put out of order and are very delicate. For simplicity, ability to stand wear and tear, quick carboning and and cleaning, ease of inspection and repair, quick handling and connecting, the American clutch lamp has not been surpassed.

In England the electrical regulation of the lamp is mostly mechanically differential, while in Germany as well as in many other countries, the shunt lamp—filled with a shunt magnet, which strikes, regulates and feeds the arc—has displaced the differential type to a great extent. Of late, high tension series arc lamps have come into use in our country, which are focusing, encased, of the clutch type, short length, ornamental in their outer appearance and fitted with a single pair of carbons for all-night lighting. Double carbon lamps are very seldom used at present in new installations, single carbon lamps with ⅝-inch carbons and the necessary length for all-night lighting take their place. Double carbon focusing lamps are used in England; ⅝-inch or 11-16-inch carbons are used for all-night lighting elsewhere in Europe.

Very little need be said about the European solid and cored carbons. They are used extensively here and are well known. The purpose of the core is to anchor the arc and keep it from wandering about, which results when the section of the carbon is too large in proportion to the current. The core decreases the resistance of the arc by the higher conductivity of the vapored material and allows a lower lamp voltage. Coated carbons are unknown abroad and at present are used here less than heretofore. Their use was justified in the earlier days,

when the resistance of the carbons was high and their life short. The thin coat of copper which surrounds the lower part of the peak of the negative carbon where the temperature is not high enough to melt it very readily, intercepts a good deal of the light. The molten globules of copper which drop on the glass globe and adhere to it account to some degree for the breakage of the thus disfigured globes. It is just as important to use good carbons and of the proper size as it is to employ efficient machinery. Else the advantages gained by one are offset by the disadvantages of the other.

To the progress in the manufacture of carbons in due the perfection of the long-burning arc lamps with enclosed arc. The arc in these lamps is surrounded with a small glass globe which is closed airtight at the bottom. At the top it is closed in such a manner as to allow the passing through of the positive carbon, the escapement of the products of combustion and the entering of fresh air. The oxygen of the air combines with the free carbon to CO_2 and CO and prevents its deposit and blackening of the globe. The lamp, which has become standard in the United States—abroad it is hardly in use at present—consumes 4.5 to 5 amperes at a pressure of 110 volts. The arc voltage is about 80. The remainder is taken up in a resistance which serves for the steadying of the arc. Aside from the great saving in carbons and attendance these lamps have the advantage, that they can be connected singly with a 110-volt circuit, whereas thus far constant potential arc lamps had to be run in pairs on 110 volt circuits. Long life arc lamps require when run singly, only a simple mechanism, with a main circuit magnet; they are perfect spark arresters. The double globes, with which the lamps are fitted, diffuse the light very evenly when properly selected.

Clear glass globes for street lighting are solely used in America, while abroad diffusing (opalescent, opaline, alabastrine) globes are used. European critics who usually describe these clear globes as a mere protection against the weather have often made them the target of their sarcastic remarks and have blamed the American public for the poor protection they afford the eye. Of late, however, opalescent globes have come into use. Different attempts have been made to reduce the loss in light produced by the use of the diffusing globes in outside service and to gain a better distribution. Although these attempts are old it is only since a short time that they have reappeared again greatly improved and modified in France in the holophane or entirely luminous globes. The outer surface of these clear, transparent globes is covered with a large number of very small horizontal ribs and groovings (prisms). They have two faces, one reflecting and the other refracting, and spread the light vertically. The shape of these prisms is different according to their relative position to the light. The inner surface of the globe is covered with a large number of vertical flutings, which spread the light horizontally. The flutings are concave at the bottom and separated by narrow ribs. The loss in light is very small compared with other diffusing globes, and the light is better distributed. Holophane globes are expensive at present, are difficult to clean, are split in two halves, and require special fittings for their support.

Two part globes are sometimes used in France where for street lighting the harp and hood is in very extensive use for the rigid support of lamps on posts. Quite sharply marked from this is the German method which supports street lamps in a so-called bishop's crook, a straight ornamental stem with a crook at the end—in such a manner that they can be lowered for the trimming. This avoids the use of a ladder or of steps on the post, but the line wires hang flopping about, which does not add to the beauty of the post or to the insulation resistance of the net. Where high voltages are used lamps are rigidly supported on the post and carefully insulated from the ground. The American hood with its wooden hangerboard and post answers these requirements. Since the voltage on arc circuits has in late years been nearly doubled, the hangerboard and hood have been discarded; with the outside exposed binding posts of the lamp located in the inside, the weather-proof lamp is insulated suspended on the post.

Arc lighting is by far not in as general use abroad as it is here. Public street lighting (see Prof. Blondel's table above) is very often confined to the main thoroughfares. The conditions under which arc lighting developed in America and Europe differ greatly, as shown, and the results are a consequence of these varying conditions.

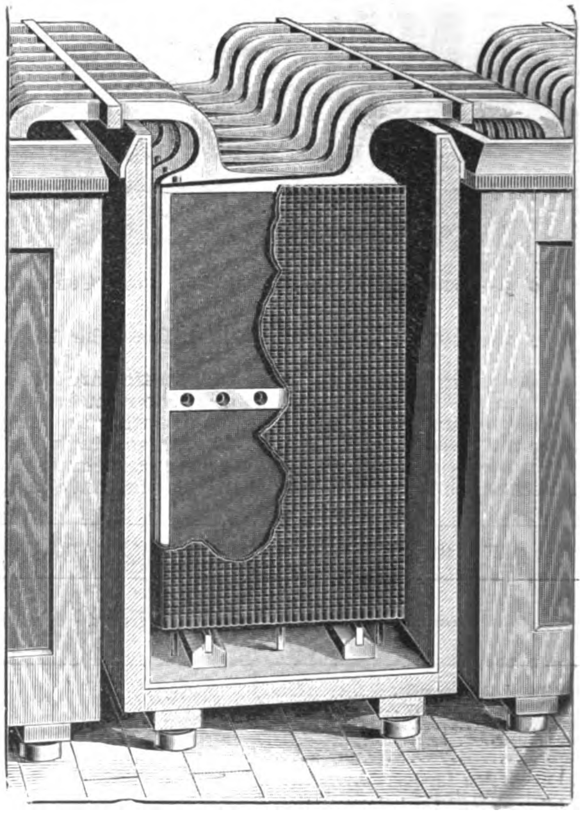
ELECTRIC LIGHTS vs. CRIME.

"There has been a remarkable decrease in crime," remarked Justic Potts to a Jersey City, N. J., "Journal" reporter. "I used to have an average of twenty to thirty cases daily, but now the average is down to single figures. I attribute it to the improvement made in the lighting of streets. The decrease began when the electric lighting system was extended. Criminals shun the light; they operate in the dark. It proves that the lights are a great protection to the community."

THE WILLARD CENTRAL STATION STORAGE BATTERY.

Owing to the rapidly increasing field for the use of storage batteries in central station work, trolley regulation, etc., it has been found necessary for manufacturers to pay more attention to this class of work than heretofore. The accompanying engraving represents one of the large Willard station cells designed especially for the above services. This cell possesses valuable and interesting features. It will be seen that the main feature is its perfect insulation. Each positive plate is encased in a corrugated highly perforated rubber cell or sheath.

The plates of the cell are formed by a special process which only occupies a period of three hours; They are made of pure rolled lead without joints or solder. The size of the plate in the cell illustrated is 16 in. x 34 in. No paste or pellets are used, the active material cannot possibly fall out, and the plate is claimed to be practically indestructible.



THE WILLARD CENTRAL STATION STORAGE BATTERY.

The supporting perforated cell is made of pure hard rubber and perforated so highly that there is a perfectly free action of the electrolyte. The internal resistance of this cell is very low. In a recent test of one of these cells the voltage remained practically constant in an eight hour discharge until the last fifteen minutes, dropping from 1.9 volts to 1 volt almost instantly.

The manufacturers of this battery, the Willard Electric & Battery Company, of Cleveland, O., are in position to furnish plants of any size up to 20,000 amperes.

Among the many plants of this type of battery installed by the Willard Company, is that of Mr. J. D. Rockefeller at his summer residence at Forest Hill.

LIGHTS PUT OUT BY EELS.

Ten eels caused trouble at the electric power station of the Attleboro street and commercial lighting systems recently. The station uses water power and steam, and while the water wheel was doing its work 10 large eels became tangled in the wheel. The wheel stopped and lights about the town went out. Next day the wheel was taken apart and the eels were found. They measured, on the average, three feet in length and from two to three inches in diameter.

ELECTRIC TRANSPORTATION

REQUIREMENTS OF HIGH SPEED AND HEAVY ELECTRIC TRACTION.[1]—I.

BY HAYWARD COCHRANE AND E. J. SWARTOUT.

IN presenting this paper we have tried to bring out what seem to be some of the most practical conclusions of the best authorities, to condense these into practical form and to suggest some outlines of what we consider to be the best results obtainable from the use of electrical machinery as it is now manufactured.

Mr. William Baxter, Jr., in a series of articles in The Electrical Engineer of 1896, gave data to prove that there would be a marked economy in coal consumption by the adoption of electric traction on roads now operated by steam. He showed that the cost of coal on trunk line steam railroads was about 10 per cent. of the total operating expense; that the substitution of electricity would reduce this item to about 4½ per cent. of the operating expense. If such a saving as this could be effected on roads where the stops were few, a much greater saving ought to be made where the stops are frequent. Steam locomotives when starting trains are working at a very low economy, whereas an electric motor would consume energy more nearly in proportion to the work to be done.

Mr. O. T. Crosby ("Limits of Steam and Electricity in Transportation") states that the repair bill for electric railway motors would not exceed 30 per cent. of that for steam locomotives. Electricity would therefore effect a marked reduction in operating expenses over steam in repairs alone. The elevated roads in Chicago use motor cars equipped with two General Electric motors of 100 horse power nominal capacity, and a drawbar pull of 2,000 pounds each at about 30 miles per hour with 33-inch driving wheels, or 2,700 pounds each at about 20 miles per hour. The series-parallel method of control is used. A few motor cars were equipped with four 100 horse power motors and were tested with two coaches, the loaded motor car weighing 70,000 pounds and each coach loaded to 42,000 pounds, making a total train weight of 154,000 pounds, or 77 tons. This train, we are informed, was run at a speed of 30 miles per hour on a level track. The weights of cars empty were as follows: Motor car, 60,000 pounds; coaches, 32,000 pounds. In case of the two-motor equipment, the motor car with two coaches, which is an ordinary train, gives a total train weight loaded of about 147,000 pounds, or 73½ tons, assuming 10,000 pounds per car as full load and an empty motor car as weighing 53,000 pounds, with a maximum two-motor elevated train of one motor car and three coaches of 42,000 pounds loaded (which is a rush hour train). This gives a total train weight of 159,000 pounds, or 94½ tons.

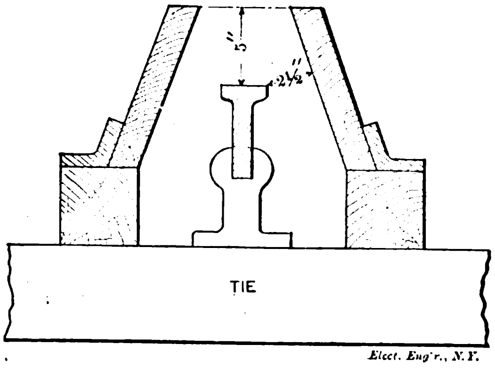

FIG. 1.

We give in the table data regarding some of the standard makes of steam locomotives, also data of a B. and O. electric locomotive used in the tunnel at Baltimore, also data of the electric motor cars on the Metropolitan Elevated Railroad in Chicago. The approximate ratio of adhesive to tractive power is given, the adhesive power being calculated on a basis of 450 pounds per ton of weight of drivers, but the steam locomotives are supplied with sand boxes to use in case the wheels slip, which probably increases the adhesive power to 600 or 650 pounds per ton. The electric motor cars or locomotives, should also have sand boxes, and these might be electrically operated.

We will now estimate the tractive power and the adhesive power of the two-motor and four-motor equipped motor cars in comparison with those of a Chicago, Rock Island and Pacific suburban steam locomotive.

Assume 12 coaches as the maximum train hauled by this locomotive and 7 coaches as an average train, and speeds of 30 miles per hour. Total weight of engine and tender, 194,700 pounds; weight on drivers, 107,000 pounds; 12 coaches loaded at 58,400 pounds, 700,800 pounds; total train weight, 895,000 pounds, or 447¾ tons. With a 7-coach train at 58,400 pounds each, the total is 408,800 pounds, plus engine and tender, 194,700 pounds, 603,500 pounds, or 301¾ tons.

The formula used by Mr. G. F. Wilson, superintendent of motive power for the Rock Island Road, for obtaining the tractive power of locomotives is,

$$T=\frac{D^2\times P\times S}{W}\text{ lbs.}$$

where D is diameter of steam cylinders in inches; P is mean effective steam pressure, 85 per cent. of boiler pressure; S is length of stroke in inches; W is diameter of drivers. For the above suburban engine, $D=18''$; $P=(160\times.85)=136$; $S=24''$; $W=63.75''$. Substituting, we have

$$T=\frac{18^2\times 136\times 24}{63.75}=16{,}588\text{ lbs.}$$

Allowing 10 per cent. for friction losses, $T=14{,}929$ pounds.

The adhesive power of the locomotive upon ordinary rails must greatly exceed the tractive power, because the rails may be wet or slippery at times. An English rule for obtaining the adhesive power of a locomotive is as follows: With dry rails, allow 600 pounds per ton of weight on drivers; with very wet rails, allow 550 pounds; with ordinary rails, 450 pounds; with misty weather, rails greasy, 300 pounds, and with rails frosty or snowy, 200 pounds. Assuming 450 pounds per ton, the above suburban locomotive would have an adhesive power, $A=(107{,}000\div 2{,}000)\times 450=24{,}075$ pounds, or about 61 per cent. greater than the tractive power.

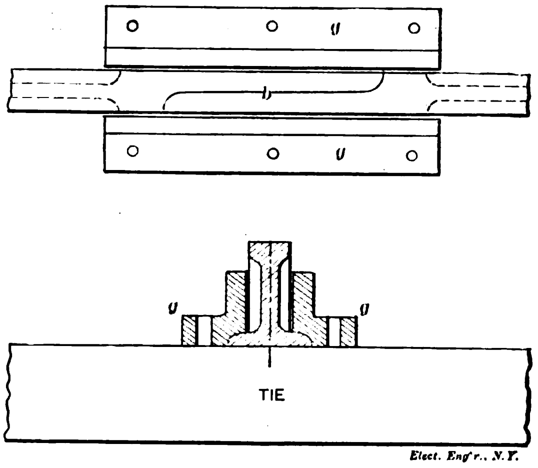
Assuming that each loaded coach of a Chicago, Rock Island and Pacific suburban train weighs 58,400 pounds and twelve coaches to be the largest train, the total train weight would be, including locomotive and tender, 895,000 pounds, or 447¾ tons. The tractive power being 14,929 pounds, there is a tractive power per ton of train of 33.3 pounds. For a 7-coach train weighing complete 301¾ tons, the tractive power per ton is 49.4 pounds. With an elevated railway train of two coaches and one motor car equipped with four motors equal to a total weight of 77 tons, where the motor car loaded weighs 70,000 pounds, or 35 tons, the adhesive power is 35x450 = 15,700 pounds, but the tractive power of each motor at a speed of 20 miles per hour is about 2,700 pounds, or for four motors 10,800 pounds. The adhesive power is therefore about 45 per cent. above the tractive power, which is lower than for the Rock Island suburban engine. The tractive power per ton of train is 140 pounds, or greatly in excess of that for the Rock Island trains.

---

[1] Read before the Chicago Electrical Association.

For an elevated railway two-motor equipment, assuming a loaded motor car to weigh 63,000 pounds with two loaded coaches each of 42,000 pounds, or a total train weight of 147,000 pounds, or 73½ tons, the tractive power would be that of two motors of 100 horse-power each of 2,700 pounds drawbar pull, or 5,400 pounds. Assuming the weight of motor car on drivers to be 35,000 pounds, we have the adhesive power equal to (35,000 ÷ 2,000)x450 = 7,875 pounds or about 45 per cent. more than the tractive power. The tractive power per ton of train is 73.4 pounds. For an elevated train of one motor car, loaded, equipped with two motors, and three loaded coaches of 42,000 pounds each, the total train weight would be 189,000 pounds, or 94½ tons. The tractive power would be 5,400 pounds. and the adhesive power 7,875 pounds. The tractive power per ton of train would be about 57 pounds, which is low for a service where the stops are so frequent.

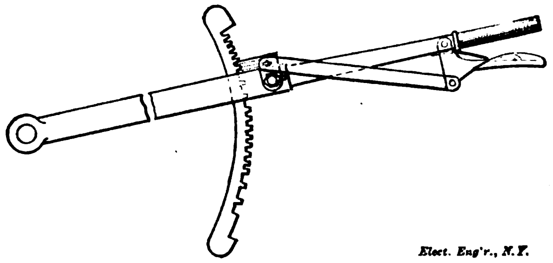
The adhesive and tractive power per ton of train should be much greater for frequent stopping than for a suburban service like that of the Rock Island road, where there are but four or five stops in 8 miles. The motors used on suburban railways should be linked to both axles so that the whole weight of the motor car would be effective in giving adhesive power. The motors moreover should be designed for a much greater weight per horse-power since the trucks are crowded with them as they are now built; larger drivers as well as slightly longer trucks would probably be required. If the motors were designed with a greater weight per horse-power, they would be less likely to heat seriously when run continuously under full load. It would be advisable, moreover, to have upon the motors a commuted field winding for use in connection with the series-parallel method of control such that a greater number of safe and fairly economical running speeds could be had in place of the two running points of the present series-parallel controller. Running in series may give too slow a speed, while running in parallel may give too fast. If, however, the motorman can have the option of about six running speeds, it would be much easier for him to keep on schedule time. By having heavier motors per horse-power and more running points, the acceleration and running of trains would be accomplished far more economically and satisfactorily than at present. The passenger coaches and trucks need not be any heavier than now built, and might be considerably lighter. The double spring suspension of motors should be adapted, as tending to prolong the life of rolling stock, and of rails not cast welded.



Elect. Eng'r., N.Y.

FIG. 2.

The third rail, wherever used, should be protected by guards so that trackmen would be comparatively safe while discharging their duties. Fig. 1 shows a form of trolley rail which we think would be better than the present form for using with high guards. This rail could be easily supported by insulating brackets at intervals and would be less likely to cause lodging of snow in winter. The top of the guards should be raised at least five inches above the top of rail, and there should be 2½" or more between the rail and either guard at the sides. For the sake of obtaining easy riding trains and saving to rolling stock, it would be advisable to cast-weld the rails together and to have expansion joints (Fig. 2) at such intervals as might be found necessary to prevent too great a movement of rails at the joints. At the take-up joints (b), Fig. 2, the rails could be specially designed, with each half equal in cross section to the main cross section of the standard form, there being no web, but the width at top being retained down to foot of rail with guides g g at the sides to keep the rails in place.



Elect. Eng'r., N.Y.

FIG. 3.

The motorman's cab should be arranged as follows: His seat should be from 4 to 6 feet back from the front window (this distance being easier for his eyes) and at the right hand side of the cab. A sliding window should be placed by his seat to enable him to look out easily upon the track or the train whenever necessary. The painting of the cab should be dark so as to relieve the motorman's eyes from all glare. The controller should be operated by a horizontal lever (Fig. 3) instead of a crank, the lever being arranged with a dog engaging in notches which give the required speed combinations.

AMERICAN STREET RAILWAY FINANCE.—IV.

BY E. E. HIGGINS.

THE question of power station is physically at the root of the whole operating plant of an electric railway, but commercially it is not, because the cost of power is so small a proportion of the whole expense. The power station, however, is usually the pet of the street railway managers, and it is given more attention perhaps than is really due to it from some points of view. In the original power stations a 150 kilowatt machine was a monster, a subject for admiration, and was only put in after considerable experience with 50, 60 and 80 kilowatt machines had demonstrated that they could be replaced easily by larger ones and to advantage. Since that time we have gone by successive leaps to 500, 1,000 and 1,500 kilowatts, or 2,000 horse-power units. We have passed from belted machines, high speed engines, to direct connected engines and generators, the engine speeds going up, and the dynamo speeds coming down to meet each other, until now we have engines which are run up pretty nearly to the limit of speed and dynamos which could easily be run at greater speeds for great output, but have to be run less economically as far as interest on investment is concerned in order to be direct connected to the engines. We find coincidentally with this that the areas of the power stations are coming down to very moderate limits, and that the cost of real estate is therefore becoming a less marked feature of street railway investment. I imagine it would be surprising to make a comparative estimate of the cost of real estate and buildings necessary for operating an electric railway plant with those of the buildings necessary for operating a horse railway plant of the same size. I think the figures for the horse road would be several times those for the electric road.

The boilers used in street railroad work at the present time are, almost without exception, of the water tube type, although there are quite a number of horizontal tubular boilers in use. The principal advantage claimed for a water tube boiler is the quickness with which it answers to the many calls for power which are put instantly, a thousand times a day, on the steam space. The more sluggish horizontal tubular boilers sometimes have pretty dangerous conditions developed through their inability to quickly respond to these calls, particularly if the surplus of water is small.

As far as the ordinary features of the boiler house are concerned, these are known to all and may be passed over briefly with the statement that there are self-feeding grates, grates for using small coal—buckwheat and slack—and a good deal of care is taken latterly to prevent the formation of smoke in the furnace and chimney, by providing more perfect combustion. It is generally conceded that smoke consuming devices do not reach the root of the difficulty and you must go further back and get at the heart of the problem in securing perfect combustion of gases in the furnace. The engines which were originally of the high speed type run with belts, are now, as I said before, of much lower speeds, and Corliss valves are used in a large proportion of the engines. There are other valves which have given excellent service, and there are medium speed machines which some people swear by, but as a rule I think no one would hesitate to-day to put in direct connected generators in any plant of 500 kilowatts capacity.

As an illustration of the difference between American and foreign engineering a curious thing came to my attention recently. A road serving a German city of about 175,000 people is actually building seven power stations, each having a capacity of about 300 kilowatts, to operate the comparatively small system of only sixty or seventy miles of track. It seems a rather strange thing to increase stations in this manner and to multiply the original and operating costs. The idea in this country is concentration, although I believe the idea of concentration can be carried too far and has been in some cases. I think we are coming to a point where the burden of copper is going to be too much to be stood and some relief must be found.

The efficiency of our dynamos is so high that it seems difficult to improve them. I imagine that this is perhaps the most stable part of a street railway plant as far as efficiency and intrinsic economy are concerned, but, of course, improvements may come even here, though in directions other than efficiency. Switchboard appliances are all quite perfect. As to the methods of power station distribution there is nothing special to be said, except that I believe that the power coming out of a station should be metered, and it is not metered generally enough at the present time. The true basis for the determination of comparative power station economy between systems, and from year to year on the same system is found in the kilowatt hour unit.

Water power is used in a good many places and with considerable success, the form of regulation varying according to the amount of power. Where the power is ample for all requirements and the surplus cannot be sold there seems to be no material objection to regulating the power as is done in one case by the introduction of rheostats, to take up the surplus power, the rheostats being switched in automatically as the current consumption of the outside circuits goes down. It is an extremely wasteful means of regulation, and if you did not have Niagara Falls behind you, you could hardly use it. There have been devised excellent automatic regulating gates so that the output is not difficult to govern and fluctuations of electromotive force and current can be taken care of with only moderate variations of electromotive force.

I am inclined to think that on the present lines of power station development there is little to be expected in the future. Steam engineering in its present state has been the result of so many years of development and study and investigation that we can hardly get above the present economy in such engines and boilers as we have to-day, and, as I have already said, the efficiency of dynamos is so great that the consumption of coal per kilowatt output is about as low as we may expect to find it with any of the present lines of engineering. There are two possibilities of the future, however, which must not be lost sight of in providing against contingencies. One of them is the much longed for direct conversion of coal into electricity. There is here an opportunity for saving perhaps eighty-five per cent. of the operating cost. The actual saving may be only fifteen to twenty per cent. of the total energy of coal and still it would double the present economy. There is another field which is nearer than that perhaps, and that is the use of turbines instead of engines. This improvement leads less to economy in operating cost than to heavy reduction in the investment cost. The economy of turbines is likely to be slightly in excess of engines, while the first cost of engine-dynamo and units may be only one-tenth or one-twentieth as much. I think we are nearer the turbine era to-day than ever before, and I am inclined to think it is only a short time away.

I have examined the operating figures of 69 railway power stations in New York and Massachusetts for 1896, as to the cost of electromotive power. The costs in Massachusetts include the repairs and renewals of power house apparatus, but this is not included in New York State. Of the 69 roads there are only 4 which are operated at less than $.01 per car mile; 12 at from $.01 to $.015; 16 from $.015 to $.02; 20 from $.02 to $.03; 9 from $.03 to $.04, and 6 from $.04 to $.05. These figures show that in the larger cities the cost of operation is usually smaller, but there are exceptions in all these cases.

The distribution circuit is always an interesting part of a street railway plant. There has not so far been any material variation in the practice of adopting a direct current, constant potential system of distribution, at a pressure of 500 volts. Experiments with less voltage were early given up and the higher voltage is used. The series system has much to commend it theoretically but has not proved a success and there are very great difficulties in the way of success on any large system. The alternating system we hope will soon come to perfection and will solve many problems that are now troubling us.

One most important thing wanted is a solution of the copper problem. It is not a pleasant thing to have to put a whole copper mine in a city, and there is certainly a chance for great reduction in that item of cost by the alternating current. There is a still greater opportunity for it in the direction of doing away with motor commutators and all the commutator difficulties which, as we know, are a large proportion of the motor difficulties in toto.

The three-wire system has been thought of in connection with street railroad work, and experiments have been made with it, but it has not been considered feasible for various reasons, among them, the difficulty of crossing wires at branches with 500 volts difference of potential between them. This is a serious and in some cases a prohibitory matter. The heavy cost of feeders in the distribution system is a serious burden on the roads and is constantly growing heavier with the increase of the number of cars called for by population increase and extensions. It is customary to divide the overhead circuit into a larger or smaller number of sections and to have the feeders run to the station from those sections. Originally there was a little different arrangement of feeders by which the sections of the trolley wire were made smaller and tapped into the same feed wire with fuses or some automatic cut-out arrangement so that if a section 1,000 feet in length gave out, it would disconnect the section from the continuous feeder but would not blow any cut-out at the station. It has the disadvantages that when there is trouble on the line, you have to get a repair wagon out as quickly as possible to locate the trouble and put in a fuse. The trouble may simply have been a ground on the motor, and cars had to be stopped till the fuse was put in. This system has been almost entirely discarded in this country, but I see by the Board of Trade regulations in foreign countries it is now used quite generally abroad. I think they will soon discover that changes are necessary.

Various methods of reducing the burden of copper have been devised, among them the "booster" system. This is a very ingenious and pretty system. Its operation is very generally known and it will hardly be necessary for me to describe it here. I think nothing need be said about the overhead construction except that in general it is very good. Iron poles are used almost universally now in our principal cities and can be made ornamental and will last longer, probably, than wooden poles will, although we have no actual knowledge on that point from experience. The span wire construction is light and strong. Altogether we seem to have gone pretty nearly as far as we can go in perfecting the overhead construction. There is a possibility of doing away with frogs and switches, and quite a little of the special work in that way, by the adoption of a trolley other than the wheel trolley. At present such trolleys are in quite general use abroad and to some extent in this country. There is also another means of doing away with some of the disadvantages on a single track, and that is by running two trolley wires along the track, branching out at turnouts so as to make it unnecessary for the trolley to leave the wire at any time. The copper for two trolley wires is usually necessary on the line, and there is no reason why this should not be an excellent form of construction.

THE COMPRESSED AIR MOTOR IN NEW YORK.

"And things are not what they seem" is an appropriate quotation sometimes. The subjoined has just been printed on the editorial page of the New York "Sun." We are sorry for that paper and for Mr. Elias:

New York, March 31, 1897.

E. A. Willard, Esq., American Air Power Company.

Dear Sir: Your cars, operated by compressed air, have been steadily operated on the 125th street line of Third Avenue Railroad Company since the 3d of August last.

They have been easily handled, started, stopped and reversed, the last-named quality being a very desirable feature, reducing the liability to accidents.

Of course, the advantage of a motor that operates independently of connection with any subterranean motive power is apparent.

I have not been able accurately and definitely to determine relative cost of this compared with other motors, but am quite sure that it is not greater, and am of the impression that it is less than animal and probably less than cable traction.

The motors are capable of attaining high speed and overcoming considerable gradients. Very truly yours,

A. J. ELIAS, President.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—VIII.

BY JOSEPH APPLETON. (Copyright, 1897.)

FIG. 23 illustrates an automatic underload switch and Fig. 24 an automatic overload switch.

An additional feature, which is sometimes of great service, is an arrangement whereby the gas or oil engine can be started by running the dynamo as a motor supplied by current from the battery; this requires simply an ordinary motor starting box with short circuiting device to be used when the plant is running under normal conditions. This feature is very convenient and relieves the attendant of the trouble of pulling round the engine by hand until the explosions commence.

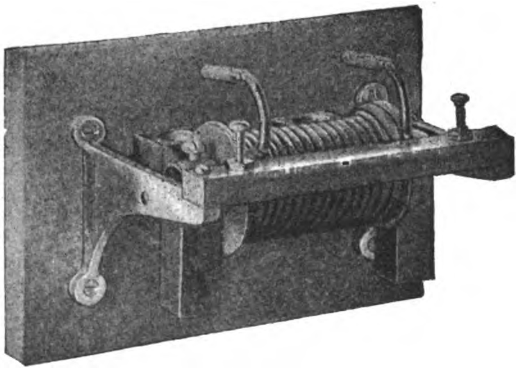


FIG. 23. AUTOMATIC UNDERLOAD SWITCH.

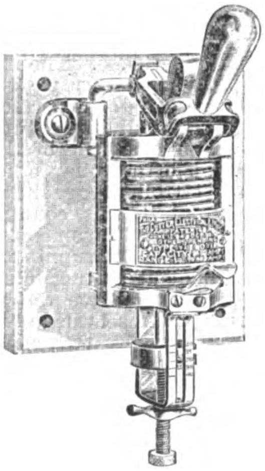

FIG. 24.—AUTOMATIC OVERLOAD SWITCH.

Another method of regulation is by means of switches which cut in and out the end cells of the battery as required, to maintain the voltage on the lamps at normal pressure. This method obviates the use of counter cells and the consequent loss of energy, but has the disadvantage of discharging the end cells of the battery unevenly, some of them being in circuit longer than others; this necessitates more attention during charge to see that the end cells are switched out of circuit when they are fully charged.

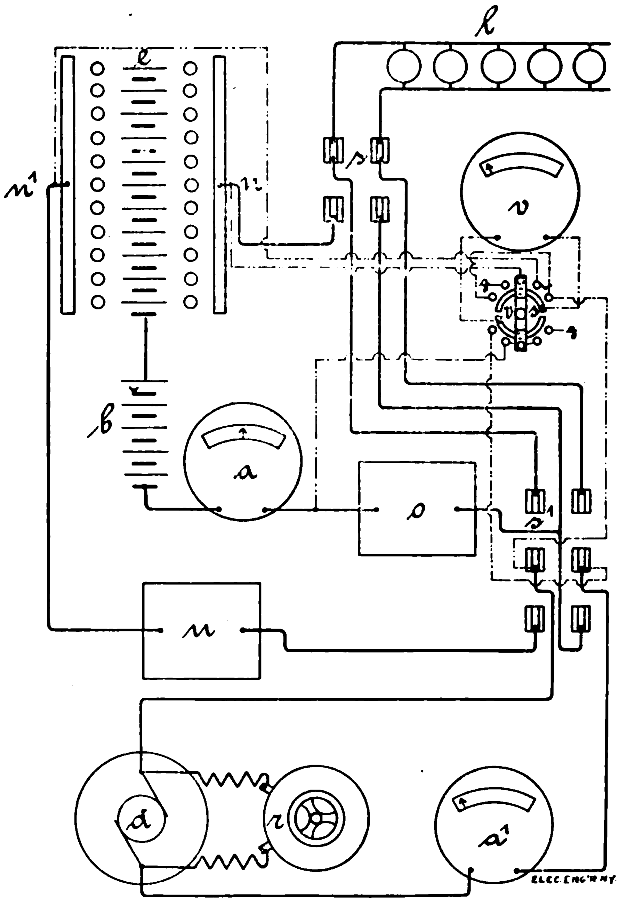

FIG. 25.—DIAGRAM OF CONNECTIONS, END CELL REGULATION.

a, a^1, Ammeters, b, Main Battery; e, End Cells; d, Dynamo; l, Lamp Circuit; n, n^1, End Cell Switches; o, Overload Switch; u, Underload Switch; s, s^1, Knife Switches; v, Voltmeter; v, s, Voltmeter Switch; r, Dynamo Field Rheostat.

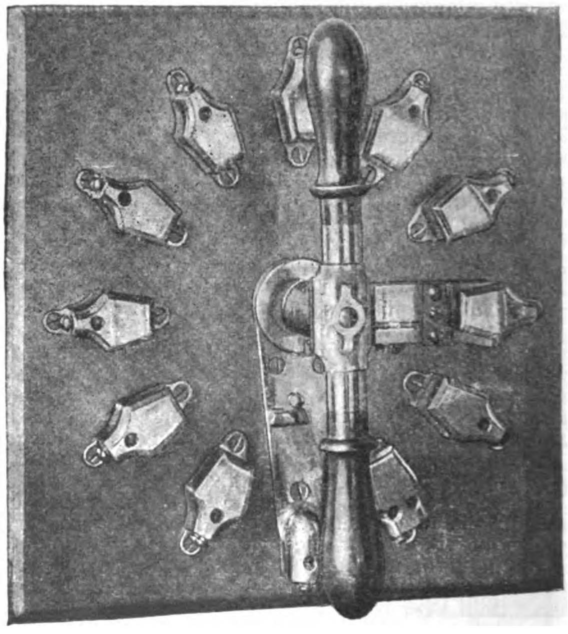

FIG. 27.—END CELL SWITCH.

The connections for this method vary somewhat from the arrangement used with counter cells; two end cell switches are required, one for controlling the number of cells in circuit during charge, and the other for regulating the number of cells in circuit on the discharge side. The number of cells which have to be controlled in this way varies from 10 to 18, according to the conditions. Fig. 25 shows diagram of connection for this method of operation, and Fig. 26 illustrates a switchboard for same which the writer installed for a large country residence; Fig. 27 illustrates an end cell switch for controlling cells as described above.

A special feature in the construction of this switch is the divided lever or contact arm; with an ordinary multiple contact switch. In switching from one contact to another, the cell connected between the two contacts would be short circuited if the contact arm made contact with one block before breaking with the other or would interrupt the circuit entirely if the contact arm broke circuit with the one block before making with the other. In order to overcome this difficulty, the contact arm is divided, a resistance being inserted between the two sections, so that in moving from one block to another, the intervening cell is not short circuited, neither is the circuit broken.

This method of regulation is generally used in very large installations where an engineer is in constant attendance, as it gives the best economy, if properly controlled; but in private installations for residences where simplicity of operation, and the smallest amount of attention are the chief considerations, the counter cell method is preferable.

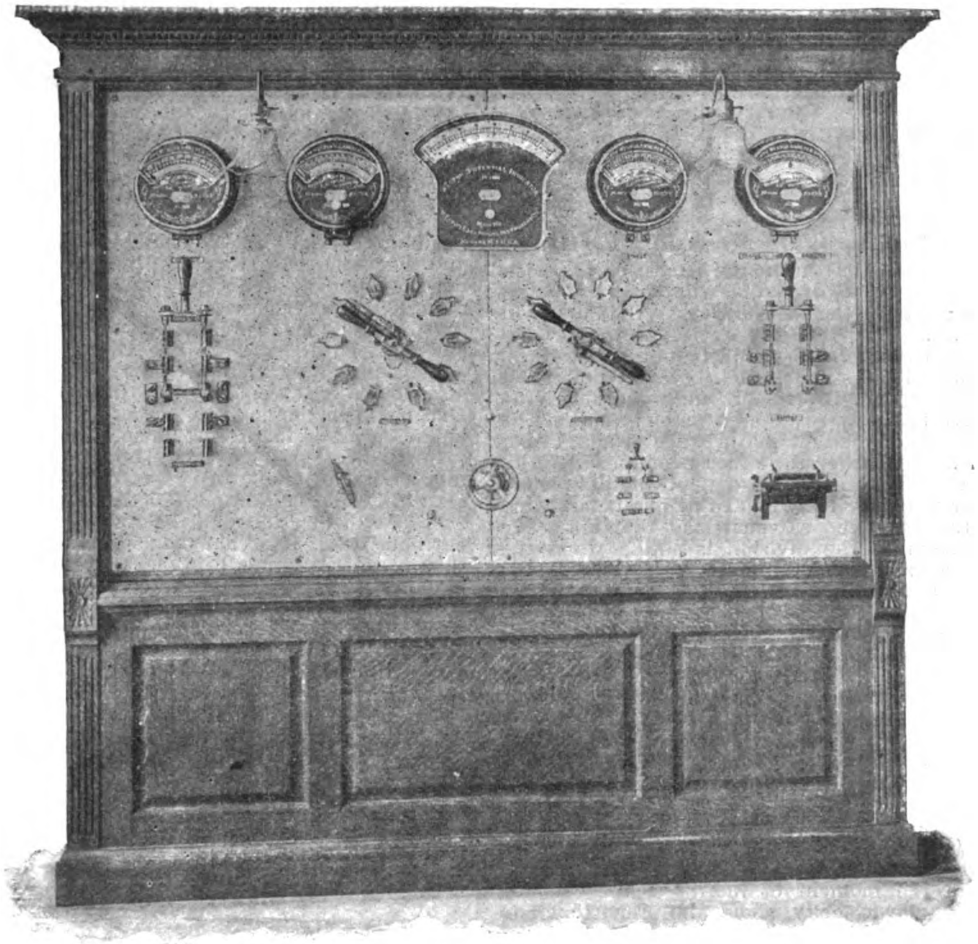

FIG. 26.—SWITCHBOARD FOR END CELL REGULATION.

A properly designed plant of this description can be satisfactorily operated by the class of help usually employed to take care of heater furnaces, if once properly instructed, and does not require a skilled mechanic. The writer has installed many such installations in all kinds of residences where they are run entirely by the gardener, coachman or handy man, requiring only a few hours' attention and giving the greatest satisfaction.

The cost of lighting a residence by means of an electric light plant of this description is very reasonable and will compare favorably with the cost of lighting by current taken from an electric light company, even where the same is available; although in the majority of cases where these plants are installed, there is no public lighting system, and the choice lies between gas, oil lamps and a private installation. Another advantage derived from the use of this system of lighting is the operation of electric motors for power purposes and ventilating.

The following figures as to cost of installation and operation are taken from a plant installed by the writer in a residence containing about 300 16-candle-power incandescent lamps.

The plant consists of a 20-horse-power gas engine, 200-light dynamo and storage battery having a capacity of 100 lamps for eight hours. The cost of installing such a plant exclusive of house wiring and fixtures is about $5,500. The cost of operation per annum is as follows:

Interest at 5 per cent. per annum	$ 275.00
Depreciation at 7½ per cent per annum	412.50
305,000 cubic feet gas	305.00
Proportion of man's time, 12 hours per week	125.00
Lamp renewals	49.00
Oil, waste and sundries	40.00
	$1,206.50

The number of lamps supplied for above cost averages 80 lamps for five hours per day throughout the year, or a total of 146,000 lamp hours for the year.

This gives a cost per lamp hour of .802 cent.; as a matter of fact, the actual cost to the owner is not so much as stated above as the man's time would be paid for whether he looked after the plant or not, and again the depreciation during the three years the plant has been in operation has not reached anything like the amount allowed, which is most liberal, considering that the generating plant is not run on an average throughout the year more than three times a week.

The cost per lamp hour for a similar residence taking current from an electric light company would be one cent., thus showing a considerable margin in favor of the private installation. Where gas is not available for the engine and gasoline is used, the cost of power would be somewhat less.

DUBUQUE, IA.—City Electrician Osborn in his annual report advocates that all interior wiring for light and power should be done under the supervision of the city, as a measure of public safety.

ALTERNATING CURRENT DYNAMOS IN PARALLEL.—II.

(Concluded.)

BY J. E. WOODBRIDGE.

ANOTHER factor that affects operation of such combinations is the relative promptness of response of the governors. If one governor responds more promptly than the other to a change of load, it will overrun, then when the other governor operates, the former will have to reverse its action, and a series of governor oscillations will be thus set up, which may cause disagreeable fluctuations in the lamps. These oscillations will be the more violent as the governors approach ideal synchronous action, as may be realized by imaging one or both of the curves in each of the figures to oscillate irregularly up and down and noticing how the horizontal or load difference between them varies with these speed oscillations. It may be readily seen that the variations in the length of the horizontal line t b between the two curves will be greater and more violent for a given vertical oscillation of the curves in Fig. 2, than in Fig. 1.

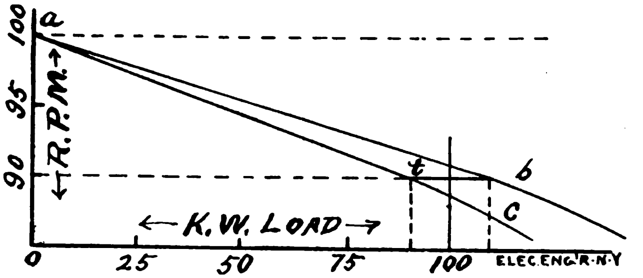

FIG. 1.

Perfect or isochronous governors would be out of the question for direct connected units in parallel, because, unless set at precisely the same speed, the faster one would take the whole load and drive the slower one as a motor; and even if set at the same speed, any slight disturbance would throw the whole of the load on one or the other machine. The division of the load would be in a state of neutral equilibrium, and either generator might be fully loaded at one instant and motoring heavily the next, the external load remaining the same. The equilibrium of the division is stable when the curves fall as the load rises, and the more rapid that fall the more stable is that equilibrium, although the regulation is poorer. Other interesting complications arise when the curves are non-similar, cross each other, or rise with the load; but are too numerous for the limits of this article.

Still another factor that has a theoretical influence on the action is the inertia of the units. When abrupt changes of load come on any engine, no matter how perfect, the speed changes somewhat before the governor acts. The inertia of each unit should be of such a value as to make these changes of speed take place simultaneously and at the same rate. That necessitates for units of different sizes or speeds that the first differential co-efficient of the inertia with respect to the angular velocity of the different units should be proportional to the rated loads of the respective units. This requires that the respective products of the moment of inertia of the rotating parts, times their angular velocity, should be proportional to the respective rated loads. This requirement is probably of no great consequence, but its application to direct connected units of widely different sizes carrying fluctuating loads might be of value.

The problem of running on a single set of bus-bars two or more groups of alternators, the dynamos of each group being belted to a separate prime mover, is solved by first mutually adjusting the dynamos in each group according to the rules laid down above for case (1), and then obtaining proper full range load distribution between the independent groups by properly adjusting the governors of their prime movers as defined above for case (2). In this second operation each independently driven group should be considered the equivalent of one dynamo of the same capacity, and treated as such. The attempt should not be made to vary the number of the dynamos on any one such engine without properly readjusting the engine governor at the same time. For example, if one of two dynamos, driven by any one such engine, is shut down, the engine, unless re-regulated, will attempt to carry through the remaining single dynamo the same proportion of the whole station load that it formerly carried through both, which will compel the remaining dynamo to carry double its due share of the load.

It is now plain also why alternators driven by engines carrying other independent loads should not be multipled. The variations in these independent loads would tend to disturb the equality of speeds between the engines, which would vary the distribution of the alternating loads. The special case of multipling two alternators coupled to the same shaft is, of course, solved by keying the armatures in such an angular position that they are in phase with each other. The fields of such a set should preferably be run in multiple arc from the same field rheostat.

In starting up a fresh unit, and switching it on to the bus-bars with a group of loaded units, the following difficulty arises. If the regulation curves are all the same (like the lower curve in Fig. 2, for example), the fresh dynamo before it is switched in will be running, say, three per cent. faster than the loaded machines. To synchronize the new machine with the others, it has been customary in European stations to provide a great bank of lamps on the station wall sufficient to load a dynamo, or some equivalent non-inductive load. The fresh generator would be loaded with these lamps as heavily as the working machines at the time, which would bring it to a synchronous speed with them; and when the phase indicator showed that the fresh machine was in phase with the others, it would be switched on to the bus-bars, after which the starting resistance would be removed gradually. Of course this accomplishes its purpose and gives absolutely no disturbance to the lamp voltage in switching, but it seems a rather unscientific method.

A better arrangement would be to provide in connection with the engine governors a hand adjusting device, by which each governor could be adjusted, while running, to any desired speed within a certain range. In starting such a machine the attendant could adjust the governor until it would run light at the same speed as that at which the working machines were running. Then with the voltage brought to the same point, and the phase indicator dark, the switch could be closed without the slightest disturbance and the machine gradually loaded up by adjusting the governor to a higher speed. By reducing the speed of any unit, it could be unloaded and switched out when light.

Such an arrangement would be, however, more valuable in affording a ready means of adjusting the distribution of the load between the engines. If any unit shirked, its load could be increased by increasing its speed, and vice versa. The wattmeter indications of a group of units could be made to harmonize by adjusting the governors, and then the ammeter readings could be brought to a minimum by adjusting the field rheostats; when it would be known that there were no idle currents being interchanged between the machines, and that they were therefore all in phase with each other and working together as though all keyed to the same shaft.

All that has been said applies equally to single phase and multiphase machines. The multiphase machine allows the application of the Siemens-Halske synchronizing device, in which a spot of light revolves one way when the fresh machine is running too slow, the other way when too fast, and remains fixed when the machines are at the same speed, its position indicating whether they are in or out of phase. The ordinary phase indicator, although it tells when a fresh machine synchronizes with the others, gives no indication as to which machine is running the faster, without some rather uncertain experimenting with the speed. A pair of resonant "humming" coils would tell the tale to an attendant with a musical ear, but all attendants are not gifted that way. A small split-phase motor arrangement, constructed as follows, will always indicate that information with single-phase generators. Let the stationary inductor of this motor be of the ordinary split-phase type, and connected to the bus bars. Let the motor be also wound with a split-phase winding connected to collecting rings with the same number of poles as the stator, and arranged for magnetic rotation in the same direction, and let it be connected to the fresh dynamo. Then the rotor will turn forward or backward, according as the fresh generator is running faster or slower than the loaded ones. Its speed will be propor-

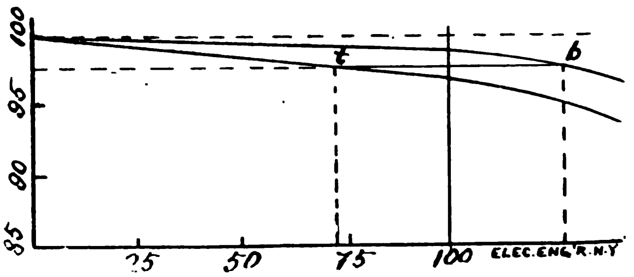

FIG. 2.

tional to the difference in speed between the fresh and the loaded generators, and its stopping will indicate synchronism. Its angular position will also indicate the phase relation.

The ideal governing arrangement (and an easily attainable ideal) for a set of engines, or turbines, each driving one of a multipled set of alternators, is a single governor controlling, through connected mechanism, the point of cut-off, gate opening or gas admission, as the case might be, of all the power units. Such a mechanism would, for example, keep the cut-off in each of a group of engines at the same point. All engines of the same size in the group would then be exerting at any load the same power, and engines of different sizes would be exerting powers proportional to the sizes of their cylinders. A special runaway governor would be necessary on each engine, to provide for any accidental opening of the circuit of that unit. This runaway governor could be a centrifugal trigger throttling arrangement, arranged to trip the valve and shut down the engine whenever the speed reached any predetermined unsafe amount.

The operating governor could be connected to the cylinders of the different engines as are the governors of multiple cylinder Corliss engines, or better by a pneumatic, hydraulic, or electric controlling mechanism; the governor itself being an accurate, sensitive instrument, placed out of harm's way, perhaps in a glass case, and driven by a synchronous motor connected to the bus-bars. The principle could be carried further, if found desirable, and a clock work or chronometric governor used, in which case the generators would make a certain number of revolutions per day, regardless of loads, and clocks could be used, driven by minute synchronous motors tapped from the lighting wires anywhere. This clock service would require no special lines, no winding devices, no batteries, and the instruments would be of the simplest. Such a plan is quite visionary, however, and is only given as an interesting possibility.

A prominent engine building house in this country has lately designed and started to build a line of marine type engines intended for direct connection to alternators, in which every element, down to such details as the width of the valves and the size of the exhaust steam pipe has been proportioned, in the different sizes, to the rated capacity of the engine. The idea was to obtain by that means proper load distribution between different sized units when running in multiple. Such extreme care for details may be valuable to their advertising and sales agents; but it is a safe prophecy that the loads will distribute themselves properly if the governors give the same speed regulation to the different sizes, and improperly if the speed regulation differs, whether the size of the steam pipes and weight of connecting rods are directly or inversely proportioned to the size of the engine.

MECHANICAL

THE WELLINGTON ENGINE AND MODERN STEAM ENGINE EFFICIENCY COMPARED.

BY HENRY E. LONGWELL.

I HAVE read with much interest the article on the Wellington series engine, appearing in your issue of April 21, and your editorial comments on the same.

This work of the late Mr. Wellington, representing as it does, such a vast amount of study and research by a man of unquestioned ability, is for this reason, if for no other, deserving of the most respectful consideration. Unfortunately however, this work is so voluminous, and of a nature so far removed from the lines along which the average engineer is accustomed to thinking, that it seems almost hopeless that a reasonably busy man should be able to fully acquaint himself with it in all its details.

Assuming that your article is a fair exposition of Mr. Wellington's theory, and that the numerical quantities, given in the illustration,—Fig.2, page 421—are from Mr. Wellington's own calculations, it is difficult to see, without throwing over all of what we are pleased to regard as knowledge of thermodynamics,—how such a system can promise, even theoretically, results equal to those actually obtained in the best modern steam engine practice.

In the first place, we may as well neglect any consideration of the efficiency of boiler and furnace, and consider only the action of the heat in the circulating fluid in the case of the Wellington engine, and the heat in the steam, in the case of the steam engine. There is no reason to suppose that the circulating fluid coming from the heater of the Wellington engine would carry any larger percentage of the heat in the fuel than the steam coming from a first-class boiler plant. The products of combustion, in the case of the Wellington engine must escape at a temperature not lower than that of the incoming circulating fluid, 288 degrees, and there are numerous examples of boiler plants fitted with economizers, which discharge the products of combustion at an equally low temperature, and which, consequently work with equal efficiency.

The measure of the efficiency of any heat engine is represented by the ratio of the amount of heat converted into mechanical work, to the total amount of heat supplied. The heat converted into mechanical work is equal to the total heat supplied, less the heat rejected.

Referring now to the illustration in your article, and supposing, for ease in calculation, that the circulating fluid is a substance of which the specific heat is unity, it will be noted that each pound of the circulating fluid in passing through the heater has its temperature raised from 288 degrees to 500 degrees, and consequently absorbs 212 British thermal units. In passing through the cooler, the temperature is reduced from 220 degrees to 50 degrees, and each pound of the circulating fluid rejects 170 British thermal units. With no intermediate losses the total amount of heat available for conversion into mechanical work would be 212—170 = 42 British thermal units per pound of fluid circulated.—Consequently the maximum possible efficiency would be $\frac{42}{212} = 19.81$ per cent.

Examining the operation from another standpoint, it will be observed that each pound of the circulating fluid in passing through the system gives up in each of the five boilers 56 thermal units, 47.6 of which are returned to it in each of the condensers, leaving 8.4 thermal units converted into work in each engine, or a total of 8.4 x 5 = 42 thermal units per pound of fluid circulated, which gives us the same result as the previous calculation.

There are a very considerable number of modern steam engines in operation which have shown actual efficiencies of 15 per cent., and over, when running under conditions of pressure and temperature much less favorable than those proposed for the Wellington engine. As a single instance might be mentioned the Leavitt compound pumping engine at Louisville, Ky., a test of which, reported to the American Society of Mechanical Engineers in 1894, by Mr. F. W. Dean, of Boston, showed a duty of 12.156 pounds of steam per indicated horse-power per hour, with an average boiler pressure of 151.6 pounds absolute, and an average vacuum of 27.75 inches. At this pressure, and with feed water at 100 degrees, the expenditure of heat would be 1,123.5 thermal units per pound of steam, 13,656.8 thermal units per horse-power per hour, or 227.6 per horse-power per minute. The heat equivalent of one horse-power being 42.75 British thermal units per minute, the actual efficiency of the engine was $\frac{42.75}{227.6} = 18.7$ per cent.

If with this comparatively low boiler pressure we can obtain an actual efficiency of nearly 19 per cent., there can be no reasonable doubt that with steam at 355 pounds, as proposed for the Wellington engine, a suitably designed condensing steam engine would give an actual efficiency far in excess of what appears to be the ultimate theoretical efficiency of the Wellington engine.

Exception must also be taken to the statement that with water and its vapor used as the working substance in all the engines of the series, operating under the conditions set forth in the example cited, the engines toward the right will do a much larger amount of work than those toward the left. If each pound of the fluid circulated gives up to each of the five boilers 56 thermal units, and receives back from each of the five condensers 47.6 thermal units, each of the five engines will have done exactly the same amount of work per pound of fluid circulated, that is, the equivalent of 8.4 British thermal units.

The volume of steam generated in boiler E would be many times greater than that generated in boiler A, and consequently the cylinder capacity of engine E would have to be correspondingly larger than that of engine A. By the use of ether or ammonia in boiler E, we might be able to obtain pressures which would admit of less cylinder capacity in engine E, but it is hard to see how the use of any working fluid can make the mechanical equivalent of 8.4 British thermal units any more or any less than 6484.8 foot pounds.

VOL. XXIII. NEW YORK, MAY 5, 1897. No. 470

THE GENERAL ELECTRIC REPORT.

WE publish this week the full text of the General Electric report, anticipatory figures from which had already been given out and have appeared in our columns. On the whole, the report is much better than might have been expected, and shows, if not an advancing business, at least a material gain in the relations of income and outgo, and in the value of the assets to the capital liabilities. It may be seriously doubted whether prices of electrical apparatus can ever again attain their former level, but the sales of $12,540,000 if taken at the prices prevalent before the panic of 1893, would represent about $25,000,000, with a corresponding, if not larger, margin of profit, for the General Electric Company is to-day doing business on a basis of economy that might fairly be called parsimonious. With that policy, however, stockholders will not complain, provided the results shall presently bring back the days of dividend and a rising market for the stock. So far nothing has been done, and nothing is hinted at in the report, as to provision for dividend resumption, but the company has, without increasing its obligations, enlarged its plant, and has also retired $750,000 of its debenture bonds. There is also reason to believe that such of the stocks and bonds as remain in the possession of the company, now of a par of $15,427,259 and carried as an asset worth $8,545,795 are likely to appreciate in value materially, in the bulk.

As to the "monopoly" of the company, it is perhaps less a fact and possibility than ever, but the relations entered into by the company with several other concerns, and not yet carried out in all the directions feasible, must be regarded as having in some measure solidified its position. There are probably more companies than ever making lamps, motors, dynamos, converters and general supplies, for lighting, railway and power work, and the tendency is to their gradual increase. But the factors making for the pre-eminence of the company, in any event, are numerous and obvious; and our conviction is that worse things might happen to the whole industry than to have the General Electric Company earning and paying good dividends by reason of its large bulk of product and the return to living prices.

THE STORAGE BATTERY OUTLOOK.

SIGNS are not wanting that the storage battery is gradually but surely looming up as a practical factor in American electric central station practice. If no other indication of this were at hand, we would be fully convinced of the fact by the letters which we have received from station managers since the publication of Mr. Joseph Appleton's series of articles on "Storage Battery Engineering Practice," in the columns of The Engineer. These communications voice the unanimous opinion of the writers as to the timeliness and value of these articles and manifest the deep interest of our correspondents in a class of work which must sooner or later be taken up by the majority of them. The letter which we publish in another column presents a typical case, in which many station operators will find a reflection of their own experience. It tells the story of a station operating at full load for less than one-half the running time and greatly underloaded during the remainder of the run. Can the storage battery remedy this state of affairs and will it pay a profit on the investment? While no answer covering every case can be given to these questions, since much will depend on local conditions, we firmly believe that the investment can be made to pay in a large majority of cases. Besides the greater economy of operating at full load, the storage battery in connection with the large majority of alternating stations would mean an increased revenue and would enable those stations shut down during the daytime to supply current during the whole twenty-four hours, which would attract not only lighting but more particularly power customers. The location of the storage batteries will probably in most cases be outside the central station as well as in it, in substations as at Buda Pest, where such an installation on a large scale has been in successful operation for several years. The manner of converting from alternating to direct current for battery charging will probably for some time yet be carried on by moving apparatus, although the static converter for this class of work has long been heralded as about ready. The rectifier, driven by a synchronous motor, has been used with success in some stations abroad, but for heavy work the rotary converter seems to be preferred in this country. The efficiency of both types of apparatus is high, so that no difficulties are encountered on that score.

What has been said regarding electric lighting service is equally, if not more, applicable to electric railway work. Already many companies are confronted with the enormous and increasing cost of feeders demanded for their heavy traffic and as lines are extended, it becomes a serious question as to the proper limits of economic operation of electric railway stations. As Mr. E. E. Higgins suggests in his paper on American Street Railway Finance, may it not be that the matter of concentration of railway power service in single stations has been somewhat overdone? Here again the storage battery, situated at the farther end of existing feeders constitutes a valuable aid to maintaining potential on the trolley lines and has already been utilized with marked success.

Thus, viewed from every standpoint the conviction is irresistable that the storage battery is destined to play as important a part in electrical work in America as it now does in Europe. When one stops to consider the relative number and magnitude of the central stations in the United States compared with those of European countries, the prospects for storage battery work in this country assume gigantic proportions.

THUNDER AND LIGHTNING AS BOGIES.

A CURRENT news item gives the results of an investigation carried out by Dr. G. Stanley Hall, president of Clark University, on the things that most excite fear in people. Of the 298 classes of objects of fear to which 1,707 persons confessed, thunder and lightning lead all the rest, although in certain localities, as, for instance, those subject to cyclones, etc., the fear of the latter predominates. It may be accepted as probably true that thunder storms constitute the most pronounced source of fear with the majority of people, due, no doubt, to the always impressive and not infrequently overpowering nature of the phenomenon. But is there any justification in fact for this fear, so far as fatal results are concerned? We believe there is not, but on the contrary, that many other causes which barely have a place in Dr. Hall's list are infinitely more entitled to the distinction as fear producers, than lightning. As proof of this we may cite statistics of the U. S. Weather Bureau. These show that for the four years 1890-93 the deaths from lightning numbered 784 or an average of 196 a year. Again, Mr. H. F. Kretzer, of St. Louis, found from the record of nearly 200 newspapers, that for the five years 1883-8 there were 1,030 deaths caused by lightning, or an average of 205 a year. We doubt whether, of the number of deaths classed as "accidental" in the whole United States, any one group can show so small a number. In New York City alone over 200 hundred people are drowned every year, while nearly 150 are burnt or scalded to death, and close on to 500 persons meet their end by falls of one kind or another. Comparing the record of 200 lightning fatalities for the whole country with the above records for New York City with its total of nearly 1,500 accidental deaths every year, it will be seen how groundless is the popular fear of lightning. It is a survival, an inherited superstition.

But there is another point in connection with this matter, which ought to be particularly comforting to city dwellers, albeit country dwellers may not be affected in a like manner, and that is, that statistics show that the risk of lightning is five times greater in the country than in the city. The cause of this immunity for city dwellers is not far to seek. It is doubtless due to the predominance of metal roofs, the well grounded water pipes in houses and probably as much as anything to the protective network of overhead electric wires of all kinds.

The popular belief that a stroke of lightning is invariably fatal is also not borne out by facts. Indeed one record specially devoted to this feature shows that of 212 persons struck only 74 were killed. Taking it all in all, there seems to be no more groundless popular fear than that of lightning. Indeed, if one can go by statistics the risk of meeting death by a horse kick in New York is over 50 per cent. greater than that of death by lightning. Yet with all the weight of statistics against its deadliness lightning will probably continue to scare people as heretofore. Perhaps, after all, there may be a more direct cause than the mere psychological one usually ascribed to it, and that is the fact that many people of nervous temperament are affected hours before the approach of a thunder storm and thus rendered particularly powerless to stand the strain which more or less affects even the most phlegmatic natures during a disturbance in the heavens.

RUNNING ALTERNATORS IN PARALLEL.

AMERICAN electrical engineers are apt to look with complacency on their record of work accomplished in the furtherance of the industry, and while they might well be entitled to a temporary rest from their labors during the past fifteen years, can they claim to have brought central station practice up to its highest state of perfection permissible by the state of the art? Leaving out of consideration types and efficiency of apparatus, is the apparatus as it stands utilized and operated to its best advantage? Take the case of our alternating stations. How many managers couple their machines in parallel to a common bus-bar? Probably not one in a hundred. And yet, how important a factor of economy this method is. The majority of American alternating stations, in fact, are running what has very aptly been characterized as "a collection of small central stations arranged for the sake of convenience under one roof," each feeding separate and individual circuits and regulated independently of all others. When to the disadvantages of such independent operation within the station are added the inconvenience and the disturbances caused thereby on the outside circuits, it is indeed a matter of surprise that no serious attempt has been made to introduce a more rational system into the alternating stations. We believe that most, if not all, types of alternators now employed commercially have been or can be operated successfully in parallel. The question, then, resolves itself into devising proper means of keeping them in step, when once they have reached that condition. It must be admitted that the methods best adapted for insuring successful parallel working of alternators, as a rule, require some study and experiment, but this ought not to constitute a bar to making the attempt. Just what conditions have to be fulfilled in the matter is very well brought out in the two articles by Mr. J. E. Woodbridge concluded in this issue of The Engineer. We believe that a careful study of the suggestions contained in them will enable the central station engineer to accomplish the paralleling of any alternating station.

CHANGING ONE'S SKIN ELECTRICALLY.

NOW that the summer is coming along, with its outdoor sports and exercises, the "summer girl" and the summer man will be exhibiting all shades and styles of sunburn. The fact that one's skin is ruddy or tanned is regarded in many circles as proof of ability to leave the city and spend time and money in pastimes; and those who cannot so indulge have hitherto been credited with closing up the front of their houses and living a secretive hermit life in the rear, to conceal their presence in town. A process of artificial sunburning by electricity has now been seriously put forward, and is likely, it is said, to be largely patronized in fashionable but impecunious circles. Per contra, Prof. Lucien I. Blake has been raising wild hopes in the breast of colored humanity by stating in a lecture at Kansas City that by means of electrical cataphoresis he expects to remove the black pigment from under the epidermis of the negro race, and thus render it easy to become white. Experiments on some parts of the body of willing subjects are reported to be going on, and the results are eagerly looked for. Care is necessary, however, in such work, for it will be remembered that in using the X-ray for removing superfluous or kinky hair, more harm than good has been done.

Stamping out heresy by killing the heretic is an old practice, but its analogue hardly goes in modern medicine. We trust that our black citizens who wish to change their color may find it possible to do so with the aid of electricity, simply and safely, for with the increase of our negro population a new and permanent branch of electrical industry would thus be created.

IT is an item of personal gossip of more than ordinary interest that Transvaal Raider Jameson is now to go to Lake Tanganyika to help in the construction of the transcontinental telegraph line from Cape Town to Cairo. He could not be better employed. Electricity will put the plucky Boer in his right place more quickly than anything else; and that line of wire across Africa is as good as a railroad.

A COMMON sight in Western cities, even the largest, is that of numbers of buggies hitched on the street in the most crowded parts of the town. But it would appear that the revolutionary trolley car is changing all that. At Columbus, O., farmers from 15 or 20 miles around, leave their traps and teams on the outskirts and board the trolley cars for the remainder of the trip. The plan is popular and works well. As the local Dispatch puts it: "They can save time, avoid the dangers of the city with horses unfamiliar with city sights, and be free from the responsibility of their teams, besides saving the expense of putting them up at a livery stable." More and more, the farmer swears not at the trolley, but by it.

THE utilization of Niagara power on the Canadian side has now reached an interesting stage. The Niagara Falls commission has notified the power company that it must begin operations on its Canadian plant by May 1 or lose its franchise to hold which it has been paying $25,000 a year. The company had applied for an extension of time, but this privilege having been denied, it has faced the problem by actually beginning work. Details for the plans of the Canadian side have already been published in The Engineer, but it is still too early to say when the work will be completed or what the exact present intentions of the power company are as to the disposal of the power that it generates. It is said that large customers stand ready for it, and it can only be hoped that this is true.

A THOUGHTFUL mayor is an inestimable boon to any community. Mayor Marshall of Corunna, Mich., has just exhibited this quality of considerateness to a marked degree by recommending that during the summer evenings the local electric light company be instructed to turn out its lights. This inaugural recommendation has caused great joy amongst the young folks, and it is said that the mayor can be re-elected if he choose or has only to say the word to be pushed for the gubernatorial office now held by Potato Patch Pingree. Authentic cases are on record where request has been made by courting lovers for the removal of an ostentatious and obnoxious arc light, but never before has a mayor come forward and thus assumed the part of a wholesale Cupid, by suggesting to shut down whole circuits, and thus smooth by darkening the course of true love.

TELEPHONY AND TELEGRAPHY

THE SYNCHRONOGRAPH.—A NEW METHOD OF RAPIDLY TRANSMITTING INTELLIGENCE BY THE ALTERNATING CURRENT.[1]—I.

BY A. C. CREHORE AND G. O. SQUIER.

THE alternating current is at present successfully employed for transmitting considerable amounts of power over long distances, and the whole system is periodically subjected to a regular and uniform succession of waves rising gradually from zero to a maximum, and then gradually decreasing, reversing, and increasing to a negative maximum. Recognizing these facts, it seemed probable that it would constitute a good means for the rapid transmission of intelligence, if the characters of a telegraphic code could be impressed upon such a current without seriously affecting its regular operation. It is to the consideration of a system of rapid transmission of intelligence by the use of the alternating current that we invite your attention.

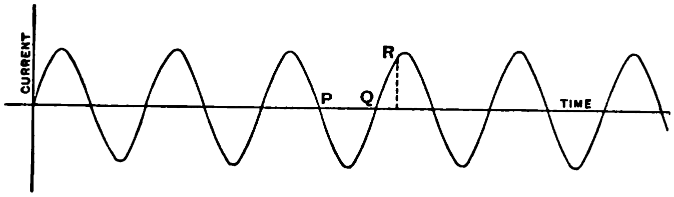

FIG. 1.

Let the sine curve, Fig. 1, represent a regular succession of simple harmonic current waves given to the line by an alternating current generator. If the current passes through a key which may be opened or closed at pleasure, then, provided the key previously closed is opened at a time corresponding to the point P of the wave upon the horizontal axis, it is known that the current which was zero at the instant the key was opened, will remain zero thereafter, in circuits which have resistance and inductance alone. Again, if the key could be closed exactly at a time corresponding to the point Q on the curve also upon the axis, the current will resume its flow undisturbed according to the sine curve. The true current obtained by opening the key at P and closing it at Q is shown in Fig. 2, where the current remains zero between these two points. If the key had been closed at any other point than Q, as at R, the current would not have resumed its flow according to the simple sine wave; but, it can be shown, would follow the heavy curve of Fig. 3, and give a succession of waves alternately smaller and larger than the normal sine wave until after a very few alternations, when it practically coincides with the sine wave. In like manner if the key is opened at some other point than P, when therefore the current is not zero, a spark may be observed at the break, and it requires time for the current to fall to zero.

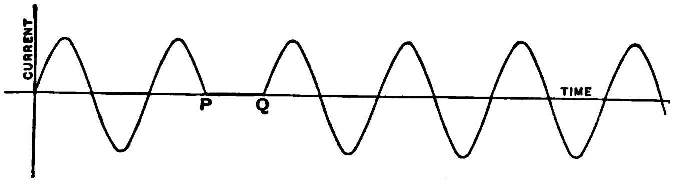

FIG. 2.

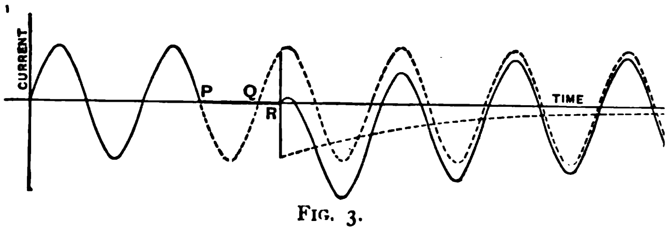

FIG. 3.

Let us consider the advantages of thus operating upon an alternating current. It is evident that the advantages above mentioned of using a system subjected to a perfectly regular alternating electromotive force, and capable if necessary of transmitting considerable amounts of power, are by this method made available. In addition, no spark is made in a transmitter adjusted to break the circuit at the exact times indicated by the curve above, when the current is naturally zero. This makes it possible, if it is found desirable, to use comparatively large electromotive forces and currents on the line, for no matter what the maximum value of the current, it is made and broken by this plan with no sparking. It is also possible to employ waves of high frequency upon the line, the upper limit obtainable from an alternator being probably much higher than can be transmitted over the line.

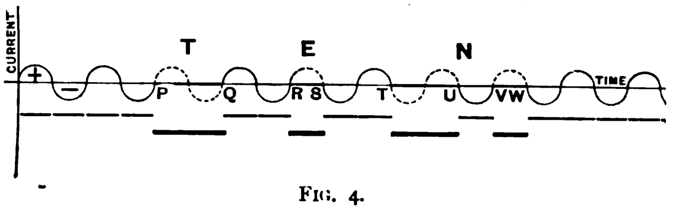

FIG. 4.

If a receiver were used which could reproduce an exact trace of the actual waves sent over the line, it might resemble such a combination as that represented by the heavy curve in Fig. 4. The sine wave continues uninterrupted to the point P when the key is opened, and it is held open for one complete wave-length P Q, when it is again closed for a wave-length Q R; then for one-half a wave-length R S; closed for a wave-length S T; opened for a wave-length T U; closed for half a wave-length U V; opened for half a wave-length V W and finally closed. By this plan it is possible to use the ordinary Continental code in telegraphy, a dash being indicated when two successive waves, a positive and a negative one, are omitted by keeping the key open, and a dot meaning where a single half-wave is omitted. The space between parts of a letter, as between the dash and dot of the letter "n" is indicated by the presence of one-half a wave-length, and the space between letters, as between "t" and "e" in the word "ten," by the presence of two half-waves, while the space between words may be represented by the presence of three half-waves, and between sentences of four half-waves or more.

If we suppose that the frequency is an ordinary one used in alternating current work, viz., 140 complete waves per second, the time required to send the word "ten" is .0394 of a second, or, by allowing three additional half-waves for the space between the words, the word "ten" would be sent just 1,200 times in one minute. There is no difficulty in using over some lines, a frequency four times as great as that ordinarily used, namely, as high as 560 or even 600 periods per second. This would correspond to speeds of 4,800 and 4,143 times sending the word "ten" per minute. The limit in each instance is only determined by the particular line used.

Hitherto it has not been pointed out how it is possible to manipulate a key at the high speed mentioned, so as to open and close the circuit hundreds of times per second as desired at the exact instants when the current is naturally zero. Evidently the proper place to manipulate such a current controller where the circuit must be made and broken at distinct points of phase, is at the generator itself, or in connection with any motor running synchronously therewith.

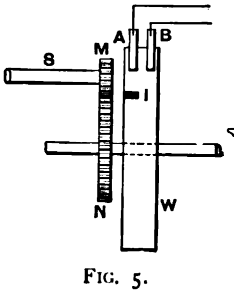

FIG. 5.

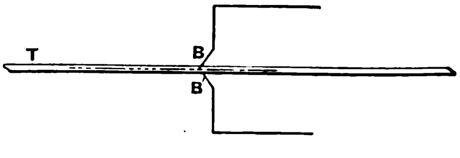

FIG. 7.

It will be sufficient for purposes of illustration to show by a special example how any single half-wave may thus be controlled at the generator; for obviously any word or sentence may be formed by a repetition of this operation.

In Fig. 5, S represents the shaft of an ordinary 10-pole alternating current generator which drives through the gears M and N, the wheel W. The circumference of this wheel is one continuous conductor presenting a smooth surface for brushes to bear upon. If the periphery of the wheel is divided for example into 40 equal parts, and it is geared to run at one-fourth the speed of the armature, each division thereof corresponds to one semi-cycle of the electromotive force produced by the generator. Upon the wheel W bear two brushes A and B carried by a brush-holder which is capable of adjustment. These two brushes are connected in series with the line, so that the current which passes in at one brush, is conducted through the wheel to the other brush, and thence to the line. The current used may be obtained from the generator, the shaft of which is represented at S, either before or after it has passed through any number of transformers, since it is the frequency alone with which we are concerned.

---

[1] Read before the Amer. Inst. Elec. Engrs, April 21, 1897. Abstract.

The line current is brought to the wheel W to be synchronously operated upon. If both brushes remain continually in contact with the wheel, the current transmitted would have the regular sine form represented in Fig. 1, and for each revolution of the wheel there would be 40 semi-waves or 20 complete waves transmitted. If one-fortieth of the circumference of the wheel is covered by paper or other insulating material as indicated at I, Fig. 5, and the brush A adjusted to ride on to and off from this insulation just as the current is changing from one semi-cycle to the next, that is, changing sign, while the brush B is in continuous engagement with the wheel, the semi-cycle represented by the section covered will be suppressed and without any sparking, even if the potential used is high. In practice, the brush A is easily adjusted to this point by moving slightly backward or forward around the circumference of the wheel until the sparking ceases. This adjustment once made, the brush is fixed in position and so remains. In each succeeding revolution of the wheel, this cycle of operations is exactly repeated, and the current sent over the line would resemble that shown in Fig. 2, having every fortieth semi-cycle omitted. It is only necessary to cover other similar sections of the circumference of the wheel in a predetermined order according to a code, to transmit intelligence over the line. The above illustration of the operation of a transmitter on this principle is given for simplicity only, and is evidently far from a practical form of transmitter.

The employment of alternating waves of different frequencies upon the same line by the method shown, does not have the same objections which exist when a constant electromotive force is used. Since the circuit is by this system always interrupted when the current is naturally zero, the frequency employed is within certain limits a matter of indifference as the line is in the same condition whether a long or a short wave is used.

A new type of receiver having no inertia in the recording mechanism was used in developing the transmitter described in these experiments. This instrument has already proved of value as a chronograph for the measurement of minute intervals of time, and for the study of any kind of variable electric currents. Although its application as a practical telegraph receiver is not at present advocated, yet the realization of a massless receiver upon different lines merits description. This receiver is based upon Faraday's discovery of a direct relation between light and electricity. This discovery was that if a beam of polarized light is passed through some substance in the direction of the lines of magnetization within that substance, there is a rotation of the plane of polarization in a direction which is the same as the direction of the current required to produce such a magnetic field. The direction of rotation is unaltered, therefore, whether the light beam advances in the same or in the opposite direction to the magnetization, so that a beam reflected back and forth through the substance several times, has its rotation increased by equal amounts each time. The medium used in the receiver is liquid carbon bisulphide contained in a glass tube with plane glass ends. There are many other substances which will answer the purpose, some better than others. This was selected because it is very clear and colorless, and possesses the necessary rotatory property to a considerable extent. It only possesses this property, however, when situated in a magnetic field of force, and the rotatory power is proportional to the intensity of the magnetic field. To produce a magnetic field in the carbon bisulphide, a coil of wire in series with the line from the transmitter is wound around the glass tube. When the current ceases, the carbon bisulphide instantly loses its rotatory power. The operation is as follows: First, the polarizer and analyzer are permanently set in the crossed position, so that no light emerges from the analyzer. A current is sent through the coil around the tube. The plane of polarization is immediately rotated. This is equivalent to rotating the polarizer through a certain angle, and hence light now emerges from the analyzer. Break the current, the medium loses its rotatory power, and there is again complete darkness. This arrangement makes an effectual shutter for the beam without moving any mass of matter. An advantage of this receiver is that the speed is not limited by the receiver but only by the natural properties of the line or of the transmitter. Used in connection with the transmitter already described, the real limit is found to be in the line itself.

In these experiments, the operation upon the alternating current according to the principles already stated, was accomplished by means of a prepared perforated paper tape, which was caused to move by the generator itself. A view of this tape, showing a method of operating upon the current is given in Fig. 6.

The line current is brought through the wires W W to two brushes B B′ not shown in the view, held by the adjustable support S. The plan of the brushes is shown in Fig. 7. One brush B bears upon the tape from above, and the other brush B′ bears from below immediately opposite the other brush so that they will meet through the perforations in the transmitting tape T. When the brushes meet through the perforations in the tape, the line circuit is closed, and when paper passes between them, separating the brushes, the line circuit is broken.

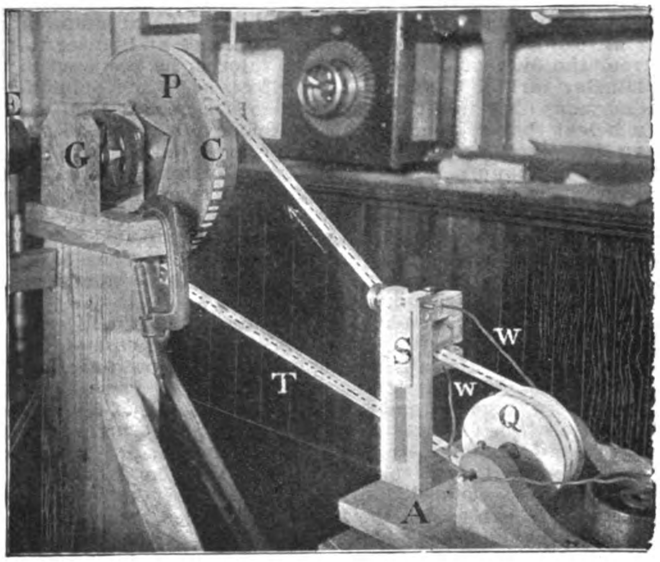

FIG. 6.

ANTI-BELL COMBINE AT MINNEAPOLIS.

A special dispatch from Minneapolis, Minn., of April 20 says: The Twin City Telephone Association which is made up of a number of companies doing business in this and immediately adjoining States, met at the West Hotel this morning to discuss means of pushing the organization and establishment of an exchange in the twin cities, which will give all of these different local exchanges a central exchange. The chief promoters of this scheme are J. E. Keelyn of the Western Telephone Construction Company of Chicago; J. F. Cass of the Western Electric Telephone system of Iowa and Southern Minnesota, and the Mississippi Valley Telephone Company of Keokuk. Representatives were present from Lake City, La Crosse, Winona, Winnebago City, Owatonna, Aberdeen, S. D.; Des Moines and other points. The purpose of the meeting was to form a permanent organization and to secure subscriptions toward the capital stock of the company to do business in the twin cities. Representatives of the Mississippi Valley company were present and became a part of the association, which would indicate that the Keelyn interests and the others will work together.

HYPNOTIZING BY TELEPHONE.

The dealers in the marvelous may derive solid comfort from the following:

Ravenna, O., April 17.—Ajo Joboe, a Hindoo hypnotist, has performed a remarkable feat over the telephone from Galion, 100 miles distant. William Morgan, at this end of the line, fell in a heap on the floor when Joboe spoke to him from Galion. Dr. White, a reputable physician, pronounced him in a perfect state of hypnotism. He said afterward the hypnotist over the wire had the same effect as at close range, and that the sensation was just the same. Joboe recently came to America.

LETTERS TO THE EDITOR

THE DUTY ON ARC CARBONS.

I HAVE read with interest the article published in The Engineer about the new duty on electric light carbons.

It seems to me that the manufacturers of arc lamps in the United States should use all their influence and power to prevent the duty of 50 per cent. ad valorem as proposed in the Dingley tariff bill, from taking effect, as in my opinion this enormous duty would raise the price of a good carbon to such a height that it would be an enormous tax upon the user of an improved arc lamp. As experience has shown in the past, the manufacturers of electric arc light carbons in the United States have not been able to turn out a carbon equal to the imported, and whatever the reasons may be of this fact, the users of a good lamp have been compelled to pay the price for imported carbons, although the price has been two or three times as high as the price of the common article manufactured in this country.

Should the 50 per cent. duty go into effect, it will certainly have the effect of still further increasing the cost of the imported article, and already importers of carbons are sending out letters, advising their customers of an increase in the price. No importer can afford to pay a duty of 50 per cent. in place of the old duty of 30 per cent without asking his customers to reimburse him for this additional tax. If, as I say, the 50 per cent. duty should become a law, the American public would be compelled to pay a price for the only carbon which they can use on their improved lamps, which would be four or five times as high as the price of the domestic article.

Who would get the benefit of it? Certainly not the American manufacturer, as even with the very much increased cost of the imported carbons, the American public would be compelled to continue using imported goods. It is not the price which has influenced the public to use imported carbons. It is simply the quality. If the American manufacturers had been able to turn out a quality equal to the imported, the imported carbon would have gone out of this market long ago, as the 30 per cent. duty which they have been paying in the past would have been more than enough to offset the probably somewhat lower cost of manufacturing in the old country.

There is certainly one effect that this 50 per cent. duty would have should the same become a law, and that is, it would handicap the progress made in the construction of arc lamps. The cost of using the improved lamp would be so high that some of the manufacturers and inventors would probably not think it advisable to spend their time and energy on still further improving the construction of the lamp with the object of giving better service to the public The arc lamp without the suitable carbons is of no value whatever, and if the only carbons that are suitable for such arc lamps cannot be bought at a reasonable amount, the improved arc lamps are of no value to the public.

I am sure you will find among your readers some that will indorse my views in the matter, and if so, I should think that some effort should be made immediately by the manufacturers of arc lamps in the United States to prevent this exorbitant duty of 50 per cent. from taking effect.

ONE OF THE PUBLIC.

Chicago, Ill.

ARGUMENTS FOR HIGH DUTIES ON CARBONS.

REFERRING to the letter in your April 21st number, under the head of "Arc Light Carbons and the New Tariff," permit me to object to the position evidently taken by your corespondent, to-wit: that the propsed tariff on arc light carbons is unjust.

Arguments so far appear to have been upon the alleged fact that the foreign production cannot be duplicated in this country. But such is not the case. I believe it cannot successfully be denied that the sole reason cored carbons have not been extensively made in America up to the present time, is that European cheap labor is so low as compared with the wages paid by our manufacturers that the foreign product can stand a 30 per cent. duty and still undersell domestic goods.

This condition has naturally discouraged much experimental work by home talent with a view of furnishing a carbon point for use on alternating circuits, and the claim made by some one recently that the material used in the foreign make-up could not be obtained except by import, is simply the ghost of a bug-bear, is not based on fact, and is too palpably absurd to be seriously considered.

More than 2,500 alternating arc lamps are in circuit in St. Louis at the present time, and the companies operating them reasonably look for a reduction in the cost of carbons as a result of legitimate competition; which, however, cannot be had until our domestic product has received assurance of adequate protection.

S. B. PIKE,
Secretary Edison Electric Illuminating Co.

St. Louis, Mo., April 26, 1897.

CHARGING STORAGE BATTERIES FROM ALTERNATNG CIRCUITS.

I am running one 1,100-volt 32-ampere alternator for commercial lighting. Can a storage battery be used in connection with it? For three hours the machine is now fully loaded, but for about four hours it is running on less than one-third its capacity.

CHARLES M. ARMSTRONG.

Barry, Ill.

Our correspondent raises a question which has probably confronted many another station manager. There is no practical obstacle whatever in the way of charging storage battery from an alternating machine as the initial source of current. All that is required is a rectifier or a rotary transformer. Both of these methods are in successful operation. In Europe several alternating current plants employ the Pollak rectifier with success on plants of moderate size. In the United States the Hartford Electric Light Company is charging a very large storage battery through rotary converters which take in alternating current at one side and deliver continuous current at the other to the storage battery.—Eds. E. E.

OBITUARY

F. G. BEACH.

We regret to announce that Mr. Franklin G. Beach, general manager of the Central Union Telephone Company, died on the night of April 28 at the family home, 1608 Forest avenue, Evanston, Ill.

Mr. Beach had been sick for three months with a complication of diseases which terminated in cerebral hemorrhage. His friends had been expecting his death for some time. Mr. Beach had been in the telephone business from the first and was one of the best informed men in that business in the country. Going to Chicago nearly thirty years ago, he was there at the introduction of the telephone, and no man in the city has been so closely identified with telephone interests and growth as he. It was frequently said of him, so well acquainted was he with the details of the business, that "he knew just where every telephone pole between Chicago and New York was located."

He was noted for his intense energy, and few men have been more devoted to their business. He was a native of Munroe, Mich., where he was born fifty-five years ago. In Evanston, where he has lived for ten years, he was popular and a favorite in the Evanston, Country and Boat clubs, being a member of all of them. He was also a member of the Lotos Club, of New York City, and was formerly president of the Chicago Electrical Society. His widow, Mrs. Elizabeth Beach, survives him.

M. C. BRISTOL.

M. C. Bristol, superintendent of construction of the Western division of the Western Union Telegraph Company, with headquarters at Chicago, died at his home there on April 30. He had been ill for two months with typhoid malarial fever. He was born in New York State in 1842 and entered the Western Union Telegraph Company's service in 1861. In 1862 he joined the United States military telegraph corps, later returning to the service of the telegraph company. He was appointed superintendent of construction of the Western division on February 1, 1879, and had been a resident of Chicago ever since.

T. C. PRICE.

We regret to announce the death by typhus, on March 31, of Mr. T. C. Price, late manager of the Electrical Supply Company, of the City of Mexico. Mr. Price, although a comparatively new man in the field, had already won a host of friends in the electrical field. His position as manager of the company has been filled by the appointment of Mr. Joseph Ketchum, of New York, who has been in the market as an engineer, manufacturer and dealer, for the past twenty years.

C. C. HINE.

The death is announced of Mr. C. C. Hine, at the age of 72, in Newark, N. J. He was an old time telegrapher and the first president of the Old-Time Telegraphers' Association in New York City. For a long time past he had been interested in insurance, and was the publisher and editor of the Insurance Monitor and Insurance Law Journal. He was a strong temperance man and an able amateur photographer.

MRS. C. H. CLOWRY

Mrs. C. H. Clowry, wife of Col. Robert C. Clowry, vice-president and general superintendent of the Western Union Telegraph company, died recently in Lincoln, Neb., of apoplectic paralysis. Mrs. Clowry was the only daughter of the late Experience Estabrook, who was attorney general of Wisconsin at an early day. Her musical compositions reached a sale of far beyond one million copies.

W. B. SOMERVILLE.

William B. Somerville, superintendent of the press service of the Western Union Telegraph Company, died in this city on April 24. He was born in Toronto fifty-seven years ago. He came to this country at an early age and thirty years ago entered the employ of the Western Union, in which he gradually rose to the responsible place he held at his death. He was greatly respected by the employés and officers of the company, and his death is sincerely regretted. Mr. Somerville served during the war, and soon after its close married, his wife's former name having been Mrs. Buckner. He leaves no children, but, besides Mrs. Somerville, several stepchildren and two sisters survive him. He had been ill about sixteen weeks, bladder trouble, which made necessary an operation, performed a week ago, being the cause of death. The burial took place at Cleveland, where his father, mother and three sisters are buried and where one of his surviving sisters lives.

Through his connection with the Western Union Telegraph Company, Col. Somerville became personally acquainted with many public men, and it was his boast that he had missed no national political convention since 1869. He was one of the leading military telegraph operators during the war.

In 1876 it was Col. Somerville who handled all the telegrams in this city on the election of President Hayes, and as all of the dispatches were signed Somerville, he had the crowds reading the bulletins wondering who Somerville was. He was a member of the Lotos Club.

MR. W. M. SKILLEN, an old time operator, and once a wealthy merchant in St. Louis, Mo., has just died at Kansas City, Mo., in the service of the Western Union Company, for whom he had worked during the past 15 years.

SOCIETY & CLUB NOTES

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Secretary Porter writes us: Arrangements have been made with the management of the International Hotel and Cataract House to accommodate members and guests attending our twentieth convention, to be held at Niagara Falls June 8, 9 and 10. Rates will be from $3 to $5 per day, American plan.

The papers to be read and topics discussed are of the utmost importance to central station managers, and the programme of entertainment embraces all points of interest in and about the Falls, which, since the introduction of electricity on so large a scale, are of unusual interest.

As the time approaches for holding our twentieth convention, unusual interest and activity is displayed by our members. The inquiries for hotel accommodations are very large, both from active and associate members and the trade in general, one company alone having reserved twenty-five rooms, another fourteen, and so on. Notwithstanding the heavy requisition for accommodations, we feel that ample provision has been made for all, as we shall practically have the resources of both the International Hotel and Cataract House at the disposal of our delegates and guests. It is well, however, to engage rooms early to insure choice locations. This can be done by addressing the hotels direct or the secretary at the headquarters of the association, 136 Liberty street, New York City.

THE TELEGRAPHIC HISTORICAL SOCIETY OF NORTH AMERICA.

The regular annual meeting of this society will be held in Washington on May 5, 1897, in the rooms of the Washington Board of Trade, No. 1410 G street, N. W. The first session will open at 10 a. m., when the routine business will be transacted. At a later session, in the afternoon or evening, formal papers will be read and discussed. Officers will be elected for the ensuing year and other important business will be transacted. Members are requested to notify the secretary whether they will be present, and they are at liberty to invite persons interested in the objects of the society to attend this meeting. Historical papers heretofore presented to the society have been printed and mailed to members. Mr. Geo. C. Maynard is secretary, No. 800 H street, N. W., Washington, D. C.

AMERICAN INSTITUTE FAIR.—The directors of the American Institute are actively preparing for what they mean to be the best show ever given by their institution. The next fair, which will be the sixty-sixth, will be held at Madison Square Garden. It will continue for six weeks, from Sept. 20 to Nov. 4. The Board of Trustees has chosen Mr. Alfred Chasseaud to be the Managing Director of the fair. The institute has established and will, until the close of the fair, maintain a temporary office for the Managing Director in the tower of the Madison Square Garden. Mr. Chasseaud is planning to amplify the departments that have become regular features of the American Institute fairs, and will inaugurate several new departures.

PERSONAL

MR. W. M. BROOKE.

The many friends of Mr. William M. Brooke, the popular representative of the Central Electric Company in Texas, will be glad to learn that Mr. Brooke's genial qualities, as well as his attention to wants of his customers, have been recognized in an unusual manner by the Texas Gas and Electric Light Association at their recent meeting in San Antonio, Texas, Mr. Goldrick, of the San Antonio Gas and Electric Light Company, on behalf of the association, presented Mr. Brooke with a handsome gold medal, inscribed "The most popular lighting man in Texas." Mr. Brooke's career in the electrical business began in the fall of 1893, when he identified himself with the Central Electric Company in a subordinate capacity, the management of which was quick to recognize his qualifications. His progress therefore was very rapid, his experience as a salesman in other lines being quickly adapted to the intricacies of the electrical supply trade. In 1894 Mr. Brooke was given full charge of the Southwestern territory, with headquarters in New Orleans. The wisdom of placing this important territory in Mr. Brooke's hands is evidenced by the action of the Texas Gas and Electric Light Association.

MR. H. B. COX.

Mr. H. B. Cox, the inventor of the Cox thermo-electric generator, has arrived in this country on a business trip from England, and will stay in this country for a few weeks to complete important negotiations and close up arrangements for the handling of his apparatus in this country, where the demand that has sprung up is at once large and insistent. The fire in his English factory has been immediately followed up by rebuilding and enlargement, and the factory has again begun to fill orders. Mr. Cox has been invited to deliver two lectures before the Royal Institution on his interesting investigations and successful work, but before returning to England has kindly promised to deliver an experimental lecture before the New York Electrical Society. Mr. Cox's address while in this country will be 126 Liberty street, New York.

MR. F. J. SPRAGUE has sailed for Europe last week on important business connected with his electrical work.

MR. F. L. WRIGHT has been elected superintendent of the electric light plant at Smyrna, Del.

MR. W. J. CLARK, of the General Electric Company, has been called to England by important business engagements, and sailed last Saturday for Liverpool.

MR. R. R. BOWKER, first vice-president of the Edison Electric Illuminating Company, of New York, is about to sail for a European trip.

MR. L. J. HIRT delivered an interesting lecture on street railway work, on April 24, before the Metropolitan Street Railway Association of New York, at its rooms on Fiftieth street. He dealt specially with underground conduit railway construction. During the evening a life-size oil painting of President H. H. Vreeland was presented to him by the employés, who had raised the amount necessary by subscription. Mr. Hirt made the presentation speech.

MR. J. P. BARRETT, on request of the new mayor of Chicago, Mr. Carter H. Harrison, has tendered his resignation along with those of other city officials. No charges of any kind were on file against him. He had been in the service of the city for 35 years, and for 21 years was head of the Electrical Bureau.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 27, 1897.

Alarms and Signals:—

SEMAPHORIC ELECTRIC SIGNAL. R. S. Roberts, Philadelphia, Pa., 581,430. Filed October 16, 1896.
Adapted for use in block signal systems on railways.

ELECTRIC CALL. H. C. West, New York, 581,446. Filed July 29, 1896.
Adapted for use separately for annunciators, alarms, or signals, or in connection with telephones.

ELECTRICAL ALARM DEVICE. J. J. Barton, Ypsilanti, Mich., 581,528. Filed December 12, 1896.
For use on call systems in hotels, etc.

THERMOSTATIC FIRE ALARM. O. A. Enholm and T. H. Beck, New York, 581,544. Filed November 23, 1896.
Employs a rotatable recessed disc containing fusible material, and a spring one end of which rests in a surface of wax, the disc and the spring being connected with the terminals of the circuit.

Batteries, Primary:—

PRIMARY BATTERY. R. R. Moffatt, Brooklyn, N. Y., 581,426. Filed Septemher 1, 1896.
Comprises a metal frame having a plurality of openings and independent battery vessels, each consisting of two cups having rims secured in the openings of the frame.

Batteries, Secondary:

SECONDARY BATTERY. V. M. Harris, Chicago, Ill., 581,283. Filed July 6, 1896.
Comprises a central metallic positive element, a porous cup surrounding the same, a mass of active material within the cup and about the element, an outer copper gauze mercury-covered negative element, a case to contain the whole, and a suitable fluid within the same.

Distribution:—

ELECTRICAL TRANSMISSION OF POWER. R. M. Hunter, Philadelphia, Pa., 581,684. Filed November 9, 1887.
A primary generator wound for currents of low intensity, a secondary generator arranged close to the primary generator, a local circuit of low resistance from the primary generator through the coarse-wire coil of the secondary generator, and an induction translating device in the long line circuit.

Dynamos and Motors:—

MAGNETO ELECTRIC MACHINE. E. B. Cutten, Atlantic Highlands, N. J., 581,340. Filed February 12, 1897.
Hand machine especially adapted for electro therapeutic uses.

ELECTRIC GENERATOR. C. C. Poole, Evanstown, Ill., 581,366 Filed February 26, 1894.
A generator of the oscillator or reciprocating type, in which the generating coils are attached directly to the piston rod.

Electro-Metallurgy:—

AMALGAMATOR. W. Wright, New York, 581,643. Filed June 12, 1896.
Means for electrically controlling the deposit surfaces of the amalgamator whereby the current may be reversed to effect a release of the materail from its receiving surfaces.

Lamps and Appurtenances:—

MANTLE OR HOOD FOR INCANDESCENT GAS LIGHTS. E. Nienstaedt, New York, 581,364. Filed March 12, 1897.
A compound for an incandescent mantle including nitrate of rhodium, nitrate of bismuth and boric acid.

REVOLVING ELECTRIC HEADLIGHT. J. Kirby, Jr., Dayton, Ohio, 581,465. Filed February 2, 1897.
Adapted for trolley cars; details of construction.

Measurement:

REGISTERING MECHANISM. W. H. McFall, Philadelphia, Pa., 581,298. Filed February 6, 1897.
Comprises a counter, a rotating cam engaging with the gearing of the counter to actuate it, and a motor for rotating the cam.

GAS VOLTAMETER. H. A. Naber, London, Eng., 581,363. Filed March 30, 1896.
Details of construction.

Miscellaneous:—

ELECTRIC GAS LIGHTER. L. L. Borradaile, Philadelphia, Pa., 581,327. Filed December 23, 1896.
Of the pendant class.

PHOTOGRAPHIC APPARATUS. J. Dennis, Rochester, N. Y., 581,540. Filed January 16, 1897.
Apparatus for the production of radiographs.

PUZZLE. J. Nesbit, Newark, N. J., 581,678. Filed August 4, 1896.
Comprises a base-board, intersecting grooves in the board, a ball adapted to roll in the grooves, and a pivotally arranged magnet on the board.

VALVE GEAR. W. Engberg, St. Joseph, Mich., 581,577. Filed February 10, 1897.
Comprises an electric circuit containing two relays, an electro magnet for each relay and provided with an armature lever, two slidable bars adapted to be engaged and locked by the corresponding armature levers, the bars controlling the position of the valve and means for making alternate ground connections for the relays.

Railways and Appliances:—

ELECTRICAL CONNECTION. H. P. Brown, New York, 581,263. Filed February 2, 1895.
Plastic alloy rail bond.

TRACK CLEANER. W. M. Brown, Johnstown, Pa., 581,264. Filed July 18, 1896.
Comprises a set of magnets carried by the car and so arranged that any magnetic material on the track is removed by them.

UNDERGROUND TROLLEY CONDUIT. J. D. Griffen, New York, 581,281. Filed May 22, 1893.
Details of construction.

SUPPORT FOR ELECTRIC RAILWAY CONDUCTORS. E. D. Priest, Schenectady, N. Y., 581,368. Filed August 23, 1896.

RAIL BOND. H. S. Newton, Syracuse, N. Y., 581,562. Filed October 5, 1896.
Consists of a thin single piece or band of copper.

CONTROLLER FOR ELECTRIC CARS. S. W. Huff, Baltimore, Md., 581,557. Filed July 26, 1895.
Two relatively movable plane parts, a series of terminals to be connected, suitably spaced apart on one of the parts, and a corresponding series of bridging contacts carried by the other of the parts, each projecting into a space between two adjacent terminals and pressed against the opposed faces of the same.

Regulation:—

ELECTRIC MOTOR CONTROLLER. W. H. Chapman, Portland, Me., 581,658. Filed February 24, 1896.
For use on shunt wound power motors.

Switches, Cut-Outs, Etc.:—

MOUNTING THE FUSES. W. W. Dean, St. Louis, Mo., 581,455. Filed September 19, 1896.
Employs wrenches for manipulating the terminals and fuses.

MOUNTING FOR FUSES. W. W. Dean, St. Louis, Mo., 581,455. Filed September 19, 1896.
Similar to above.

ELECTRIC FUSE. W. E. Harrington, Philadelphia, Pa., 581,460. Filed October 29, 1895.
Comprises a central primary section, terminal sections of greater cross-section and masses of non-conducting material arranged to surround portions of each of the terminal sections without enclosing the central primary section.

Telegraphs:—

PRINTING TELEGRAPH. J. Burry, Long Island City, N. Y., 581,411. Filed June 27, 1896.
Comprises a shaft, a loose gear thereon; a spring fast at one end to the loose gear; a spring fast at one end to the shaft; friction devices connecting the springs; and intermittently acting means for turning the shaft to wind up the spring fast thereto.

Telephones:—

TELEPHONE INSTRUMENT. J. E. Keelyn, Chicago, Ill., 51,350. Filed January 5, 1897.
Receiver in which the magnets may be readily adjusted toward and from the diaphragm.

TELEPHONE RECEIVER. W. J. Morton, New York, 581,406. Filed May 15, 1895.
Embodies a soft iron diaphragm and one or more perforated diaphragms located between two magnetic poles.

SELECTIVE SIGNAL FOR TELEPHONE CIRCUITS. H. W. Mason, New Bedford, Mass., 581,561. Filed July 31, 1896.
Details of construction.

THE STOCK MARKET

THINGS QUIET AND DULL.

The effect of conditions in Europe has been to tangle up things here in uncertainty and to bring about a little lower range of prices, although firmness is a pronounced characteristic of all good securities. The resumption of the gold basis in Austria is likely to take away some $15,000,000 of the precious metal, but it can well be spared. The redundancy of gold is, in fact, but another sign of business inactivity. It will be interesting to see whether the usual burst of springtime hope and confidence makes itself felt to any degree. Railroad returns, and retail shopping reports indicate that people are beginning to spend more freely.

Western Union on sales of 41,251 shares is off to 76¼, chiefly on expectancy of a reduction in the dividend. General Electric is stagnant around 31 to 32, with only 1,825 shares sold last week. The report given out shows a smaller business but better status. American Bell went to 224.

COPPER.

The "Iron Age" reports the New York copper market as follows: It is believed that business of somewhat extensive volume has been effected at or very near to 11c. for Lake Superior Ingot and that contracts for other varieties of the metal have been taken at prices relatively as low, but particulars are guarded very closely. It is no secret, however, that offers have been made to sell at 11⅛c. for Lake Ingot, 10⅞c. to 11c. for Electrolytic and 10½c. to 10⅝c. for casting stock.

REPORTS OF COMPANIES

FIFTH ANNUAL REPORT OF THE GENERAL ELECTRIC CO.

ANTICIPATORY figures have already been given in The Electrical Engineer of the report of the General Electric Company. We are now able to give the reports of President Coffin and Second Vice-President Ord:

Mr. Coffin's report to the stockholders says: The business of your company has suffered during the past year, in common with that of all manufacturing enterprises, from the disturbed financial and political conditions which have prevailed during a considerable portion of the time. These conditions have curtailed the amount of capital ordinarily available for the establishment and extension of power and lighting plants, and have enforced the practice of great economy on the part of its customers. As a result, the shrinkage in orders received by your company was very marked, especially during the later half of the year. This shrinkage is not shown by a material falling off in shipments, as given in the Profit and Loss Statement of this report herewith, but the amount of work in progress and unfilled orders on hand is considerably less than a year ago.

Consolidated Balance Sheet of January 31, 1897.

ASSETS.			
Patents and Franchises			$8,000,000.00
Factory Plants			3,400,002.00
Real Estate (other than factory plants):			
Edison Building, New York City		$417,584.63	
Other Real Estate		230,431.61	648,016.24
Stocks and Bonds			8,540,795.68
Cash			703,483.84
Notes and Accounts Receivable		4,578,600.96	
Work in Progress		517,866.30	
		5,096,467.26	
Inventories:			
Factories	$3,375,511.07		
General and Local Offices	621,489.32		
Consignments	37,752.65	4,034,753.04	9,131,220.30
Profit and Loss			12,957,413.40
			$43,380,931.46

LIABILITIES.		
Capital Stock:		
Common	$30,460,000.00	
Preferred	4,252,000.00	$34,712,000.00
5% Gold Coupon Debentures		8,000,000.00
Accrued Interest on Debentures	66,666.65	
Accounts Payable	402,264.81	
Mortgage on Edison Building	200,000.00 *	668,931.46
		$43,380,931.46

*Paid off February 26, 1897.

With a return to normal commercial conditions, a corresponding revival in the business of your company may be expected. The volume of business secured by it for the first three months of the current year is slightly in excess of that for the same period in either of the three previous years.

On January 31, 1895, the sum of $2,000,000 was set aside, as shown in the Annual Report of that year, to provide for shrinkage in assets, exact values of which it was then extremely difficult to fix. During the past year your directors have been able to value these items with substantial accuracy, and the $2,000,000 fund has been found sufficient and has been used to provide for the proper adjustment of all accounts and other assets for which it was created.

BUSINESS OF THE YEAR.

Gross earnings	$12,820,395.87	
Less expenses	11,207,388.65	
		$1,613,007.22
Deduct.		
Interest on debentures*	431,250.00	
Less interest and discount, and interest and dividends received on securities owned	370,479.70	
		60,770.30
		1,552,236.92
Deduct amounts written off.		
Sundry losses and allowances for possible losses	318,531.13	
Patents	349,919.20	
Inventories and consignments	61,084.36	
	729,534.69	
Less.		
Profit on securities sold and debentures canceled	136,955.85	
		592,578.84
Reduction of the deficit of previous years		$959,658.08

Additional purchases of your company's debenture bonds have been made during the year to the amount of $750,000 leaving now outstanding $8,000,000. All debentures purchased have been canceled.

The decrease in the amount of interest and dividends received as compared with the previous year, is due largely to the cessation of dividends by the Canadian company, which it is hoped will soon resume dividends on its reduced capital. As a partial offset, there has been an increase in the income derived by your company from dividends on stocks held by it in various local companies.

In the last annual report attention was called to an arrangement which had then been concluded with the Westinghouse Electric and Manufacturing Company for an exchange of licenses under patents owned and controlled by the two companies. Your directors are pleased to report that the result of this arrangement has been highly satisfactory.

The result of the work of your company in protecting its patents and enjoining infringers thereof has been especially encouraging, and a considerable number of patents of value has been acquired by it during the year. The courts have invariably recognized the validity and controlling importance of the Van Depoele patents on the electric railway trolley and switch system, and at the present time substantially all manufacturers of infringing trolleys and switches are under injunction. The company has met with no reverses in its patent litigation during the past year. Many new suits have been brought, involving important patents, and are now being actively pushed.

Consolidated Profit and Loss Account of January 31, 1897.

EXPENSES.		
Balance January 31, 1896		$13,917,071.48
Cost of Goods Sold	$9,691,504.12	
General Expenses and Taxes	1,515,884.53	11,207,388.65
Interest on Debentures		431,250.00
Sundry Losses and Allowances for Losses	318,531.13	
Depreciation of Inventories	50,354.85	
" " Consignments	10,729.51	379,615.49
Patents and Patent Expenses		349,919.20
		$26,285,244.82

EARNINGS.		
Sales	$12,540,993.88	
Royalties and Sundry Profits	279,401.99	$12,820,395.87
Dividends and Interest received on Stocks and Bonds owned	282,143.69	
Interest and Discount	88,336.01	370,479.70
Profit on Sales of Stocks and Bonds	79,816.76	
Discount on Debentures Purchased and Cancelled	57,139.09	136,955.85
Balance January 31, 1897		12,957,413.40
		$26,285,244.82

E. & O. E.

J. P. ORD, *Second Vice-President.*

The great improvements made by your company during the past year in the design and construction of its apparatus have been very satisfactory. The development in long-distance transmission of electricity and the progress made in electric railway service have been especially noteworthy. Many new enterprises, involving the application of electricity to railways now operated by steam, are under consideration, and the ensuing year promises to be marked by a very rapid growth in that field of work.

Your company has added one large factory of brick and steel construction to its plant in Schenectady during the year, besides completing and occupying another, which was commenced in 1895. Other important improvements at these works are in preparation, designed to add to the facility and economy of handling their output.

The report of Mr. Ord to President Coffin is as follows: The balance sheet and statement of profit and loss, herewith transmitted, include the assets and liabilities and profit and loss accounts of the Edison General Electric, Edison Electric Light, and Thomson-Houston Electric Companies (which, for convenience of bookkeeping, are consolidated with those of the General Electric Company) at January 31, 1897; and when "the company" is spoken of, all the above mentioned corporations are included.

---

*On $8,750,000 for ten months and on $8,000,000 for two months.

I submit explanations of what each item on the balance sheet represents.

ASSETS.

Patents and Franchises.—During the year there was expended for acquiring new patents and patent litigation, $349,919.20, all of which has been written off to profit and loss; leaving the patents franchises, good will, etc., of the company standing unchanged at $8,000,000.

Factory Plants.—This account represents the real estate (lands and buildings); machinery, tools, appliances, etc.; patterns, drawings, etc.; and sundries (fittings and other small property accounts) of the factories at Schenectady, N. Y.; Lynn, Mass., and Harrison, N. J. The lands amount to over 72 acres and the total factory floor space of all buildings is approximately 1,416,000 square feet. All are free from mortgage or other lien. These plants being a permanent investment, all expenditures for their maintenance and repair, plus an allowance to provide against depreciation, are charged to operating expenses. Their book value at the date of the last annual report was $3,468,002.00. The amount written off during the fiscal year for depreciation, over and above the total cost of all maintenance, repairs and additions, was $68,000.00—leaving the book value of factory plants at January 31, 1897, $3,400,002.00.

A summary of the changes in this account during the past year is as follows:

	Book Value Jan. 31, 1896.	Cost of additions.	Written off for depreciation.	Book Value Jan. 31, 1897.
Real estate,	$1,800,000.00	$92,092.45	97,092.45	$1,795,000.00
Machinery,	1,668,000.00	205,321.90	268,321.90	1,605,000.00
Patterns,	1.00	47,794.34	47,794.34	1.00
Sundries,	1.00	34,361.68	34.361.68	1.00
Totals,	$3,468,002.00	$379,570.37	$447,570.37	$3,400,002.00

Book Value of Each Plant.	Jan. 31, 1896.	Jan. 31, 1897.
Schenectady factory	$2,135,000.90	$2,157,000.90
Lynn factory	1,038,000.80	993,000.80
Harrison factory	295,000.30	250,000.30
Totals	$3,468,002.00	$3,400.002.00

Real Estate. (Other Than Factory Plants.)—This account represents the investment in the Edison Building, 44 Broad street, New York City, also a large building covering five lots on the corner of Avenue B and Seventeenth street, New York City, and sundry parcels of land in various places, mostly improved and rented, which have been acquired at various times, chiefly in payment of debts. All will be sold when opportunity offers.

Stocks and Bonds.—Schedule A. annexed hereto contains a list of nearly all the company's stocks and bonds which are carried at more than merely nominal values[1].

Those having a market value are carried at slightly under the price of recent sales. The book value of those not readily salable has been fixed after careful examination of their present worth.

I believe their actual present value is equal to the aggregate at which they stand in the balance sheet, viz.: $8,545,660.68. In addition, the company owns various miscellaneous securities of many manufacturing, selling and patent owning corporations, and also of street railway and lighting companies. As the present value of these is doubtful and their future value speculative, they are carried at one dollar for each lot, making in all $135.00. Total book value of all stocks and bonds, $8,545,795.68. The book value of stocks and bonds in the last annual report was $5,479,332.23. Increase, $3,066,463.45.

Although some securities have been purchased for cash, most of those acquired during the year have been accepted in payment of old indebtedness.

The principle items of the above increase are:	Par value.
Edison Electric Company of New Orleans.	
Received in exchange for the claim against the receivers of the Fort Wayne Electric Company, and for cash advanced to the Edison Electric Co. to purchase the Louisiana Electric Light Co. and build a large new central light and power station	
First mortgage bonds	$ 891,000.00
Preferred stock	1,980,000.00
Common stock	1,000,000.00
Baltimore & Ohio Railroad Co.'s receivers' certificates, received in payment of balance due for electric plant and electric locomotives for its tunnel under the city of Baltimore	323,000.00
Bonds of the city of Jacksonville, Fla., received in part payment of a lighting plant	58,000.00
Sacramento Electric Power & Light Co., received in part payment of a contract	44,000.00
Bonds of the Brush Electric Co. (the entire issue outstanding) received in payment of notes and purchased for cash	369,000.00
Bonds of the Columbus R. R. Co., Columbus, Ga., received in payment of claim against Brush E. L. & P. Co., of Columbus	50,000.00
Preferred stock of the United Electric Securities Co. bought for cash	74,200.00
Bonds of the Citizens' General Electric Co. of Louisville, Ky., purchased	94,000.00
Bonds of the Tacoma Ry. & Motor Co. purchased under old contracts with the United Electric Securities Co.	231,000.00
Bonds of the Augusta Ry. & Electric Co. received in exchange for claims against Thomson-Houston Electric Co. of Augusta, Ga.	41,000.00
Stocks and bonds received from licensees in payment of royalties	119,750.00
	$5,274,950.00

Sales of Stocks and Bonds.—The past year has not been favorable to the established policy of selling securities which there is no special reason for holding permanently, and but few have been sold since the last annual report.

Securities whose par was $326,115, were sold for	$285,829.56
They were carried on the books at	206,012.80
Profit	$79,816.76

The cash thus received was used toward the purchase of securities mentioned on the preceding page.

CASH.

The policy of the previous two years has been adhered to and sales maintained on a basis of cash or short credit to desirable customers. It has not been necessary to borrow money, nor has the company's credit been used during the year either by issuing notes, indorsing customers' paper for discount or lending its name in any way. During the year all purchases have been paid for in cash. None of the money realized from the sale of assets was required for the current business of the company during the year.

Notes and Accounts Receivable.—These accounts represent the total amount now due the company by customers. They appear in the balance sheet at an estimated realizable value (i. e., their face, less allowance for possible losses) which I believe to be a fair one. They may be classified approximately as follows:

	Face value.		
Current notes	$1,196,715.81		
Current accounts	2,901,773.96		
		$4,098,489.77	
Slow notes	766,974.05		
Slow accounts	207,188.16		
		974,162.21	
			$5,072,651.98
Due from local lighting and street railway properties owned by the company			217,700.92
Due from the Brush Electric Company			194,516.85
Total face value*			$5,484,869.75

Collection of the old indebtedness remaining from previous years has been as satisfactory as was possible under the financial conditions of the year.

Work in Progress.—This account does not include anything in process of manufacture; but represents expenditures for labor, material, etc., on 194 installations of manufactured apparatus delivered at various places $900,807.52

Less partial payments thereon, received under the terms of the contracts as work progressed 382,941.22

Balance $517,866.30

None of the estimated profit to be derived from these installations is included in the earnings of the year, and no allowance is made thereon for possible loss.

Inventories.—These accounts represent raw materials and goods manufactured and in process of manufacture at the factories; manufactured goods in storerooms of local offices and on consignment; office furniture, fixtures, instruments, etc., in the general office and in local offices; tools and materials in local repair shops; and also shipments in transit to local storerooms. All have been counted and valued item by item. Raw materials have been valued at the market prices prevailing on January 31, 1897; active selling finished and partly finished apparatus and supplies at factory cost; inactive or slow selling apparatus and supplies at about 50 per cent. of factory cost; obsolete apparatus and supplies at scrap value; and tools, instruments, furniture, etc., at present value. The inventories of the factories showed an excess over book value of $141,184.98, which is not taken as a part of the year's profit, but is retained as a reserve. All other inventories showed a shrinkage from book value of $50,354.85, which has been written off as a loss for the year. As goods are taken in and out of local office inventories at factory cost, at the time being, the bulk of the above shrinkage is due to factory costs at January 31, 1897, being lower than at January 31, 1896; and the remainder to writing down the book value of slow selling apparatus and other personal property.

---

[1] The schedules show some 71 lots of stocks and 79 lots of bonds of a total par value of $15,427,259. Eds. E. E.

*In addition, there are old notes and accounts receivable of 435 debtors aggregating $2,644,547.59 which have all been written off to Profit and Loss except the nominal book value of one dollar for each debtor. They are being liquidated as rapidly as possible.

Consignments.—Finished apparatus for novel uses has been delivered to various concerns, subject to purchase if its operation is successful. The greater part of this account represents such contingent sales, and the remainder represents apparatus on exhibition, or loaned to regular customers for temporary use by them.

All the above apparatus is charged, at factory cost, to this account at a total of	$73,729.80
Less allowance for depreciation	35,977.15
Net book value of Consignments	$37,752.65

Liabilities.—The company has no notes payable, nor is any paper bearing the company's endorsement of guaranty under discount.

Debentures.—During the year the company has purchased and canceled $750,000 of its own debentures at an average cost of 92.38 per cent.

Accrued Interest on Debentures.—This account, as its name implies, is the full amount of interest accrued to January 31, 1897, on the company's $8,000,000 outstanding five per cent. gold coupon debentures.

Accounts Payable.—This account includes all unpaid audited indebtedness. At the close of business on January 31, 1897, the unpaid vouchers on hand amounted to only $40,155.32, and none of these was due under the terms of purchase. The difference between that amount and the amount of accounts payable shown in the balance sheet, $402,264.81, represents expenditures belonging to the year, vouchered between January 31 and February 23, the date of closing the general books. The amount of vouchers which have to be carried over in this way monthly, owing to keeping the books—other than the cash book—open a sufficient time to include expenditures of a particular month in that month, is usually about $500,000.

Mortgage on Edison Building.—A mortgage, created when the company's building, No. 44 Broad street, New York City, was erected. It was paid off in full February 26, 1897.

LEGAL NOTES

TROLLEY GRADE CROSSING ENJOINED IN PENNSYLVANIA.

An important decision relating to electric and other railway companies has been handed down by Justice Dean, in Philadelphia, in the case of the Delaware and Hudson Canal Company against the Scranton and Pittston Traction Company. The Canal Company operates, as lessees, a steam railroad between the cities of Scranton and Wilkesbarre, on which about 135 freight trains are run every day.

The Lackawanna Street Railway Company, incorporated under the act of March 14, 1889, was authorized by its charter to build and operate an electric railway from a point on Center street, at the Scranton city line, over a certain route along streets and main road to the village of Moosic and to the borough of Avoca and return. This route crossed the canal company's steam road at two points at grade. This the canal company objected to and applied for an injunction against the Scranton and Pittston Traction Company, which had contracted with the electric railway company to build the road, to restrain them from constructing their grade crossings. The matter was taken to the Common Pleas Court of Lackawanna county, which finally enjoined the making of a grade crossing at Spring street, but allowed it at Wyoming avenue, in Moosic.

An appeal was taken to the Superior Court by the Canal Company, and that court sustained the judgment of the Common Pleas Court, two judges dissenting. Appeals were then taken to the Supreme Court, and it is these appeals which have just been decided.

"The reasonably practicable," says Justice Dean, "is not to be determined by want of corporate power to invade the rights of the property owner. The construction of the crossing is what the statute expressly says shall be regulated by the courts, and this with a view to avoid danger and protect the older franchise from injury by the younger one. The act of 1889 gives the right to cross at grade, but then we are met by the act of 1871, which says the court shall, by its process, prevent it, if an overhead crossing be reasonably practicable. This leaves only for the court the physical problem to be solved, by the influence warranted from the character of the two roads, the business done upon them, the topography of the territory, and like facts." * * * "If the act of 1889 does not confer upon electric railway companies those full powers necessary to their construction and corporate prosperity, the Legislature is the body to which application should be made for more extensive grants. And we may further say that after ample time for the most thorough consideration, we are determined to unflinchingly adhere to the rule announced in Perry County Railroad vs. Newport Railroad, 150 Pa. 193; Pa. R. R. Co. vs. Braddock R. R. Co., 152 Pa. 116, and subsequent cases."

The decree of the lower courts allowing the grade crossing was reversed and the injunction restraining its construction was granted.

RESPONSIBILITY FOR THE BOSTON SUBWAY DISASTER.

The report of Judge Ely of the Municipal Court, Boston, upon the inquest into the death of William A. Stuart, one of the victims of the gas explosion in the subway excavation in that city March 4, has been filed with the District Attorney. Judge Ely finds that Stuart's death was due to the unlawful act of the Boston Gas Light Company, and that the gas light company is mainly to blame for the explosion. It was, he finds, guilty of gross carelessness and negligence.

He further finds, however, that the Metropolitan Construction Company and the Transit Commission were not without fault, in that they, as well as the gas light company, were negligent in not providing inspectors and watchmen to oversee the operations attending the building of the subway under Tremont street, at or about the point where the explosion occurred.

RULES AS TO DELIVERY OF A TELEGRAM.

A rule not to deliver messages outside of a half-mile limit is held, in Western Union vs. Robinson (Tenn.) 34 L. R. A. 431, insufficient to excuse a delay in delivering message sent to a small town a few miles away, summoning a minister of the gospel to a person near death, when the rule was not known to the sender and was not mentioned by the agent who received the message about dark, stating that it could be delivered that night.

VALUE OF A SUBWAY GRANT.

A municipal grant to a corporation of the right to lay subways for electric wires under all the city streets, without reserving the power of supervision and control, not only of the work of excavating in the streets, but of all matters incident to its location, construction, maintenance and use, is held, in State, ex rel. St. Louis Under Ground Service Company vs. Murphy (Mo.) 34 L. R. A. 369, to be beyond the power of the city, although the sole purpose of the subway may be that of leasing to public wire-using corporations.

KEEPING INSULATION PERFECT.

The utmost care to keep the insulation of dangerous electric wires perfect at places where people have a right to go for work, business or pleasure is held necessary in McLaughlin vs. Louisville Electric Light Company (Ky.) 34 L. R. A., 812, although at other places very great care may be deemed sufficient. And the fact that the insulation of wires is very expensive or inconvenient is no excuse for failure to make it perfect at points where people have a right to go for work, business or pleasure.

TRADE NOTES & NOVELTIES

THE CASHIER'S ELECTRIC SAFETY CABINET.

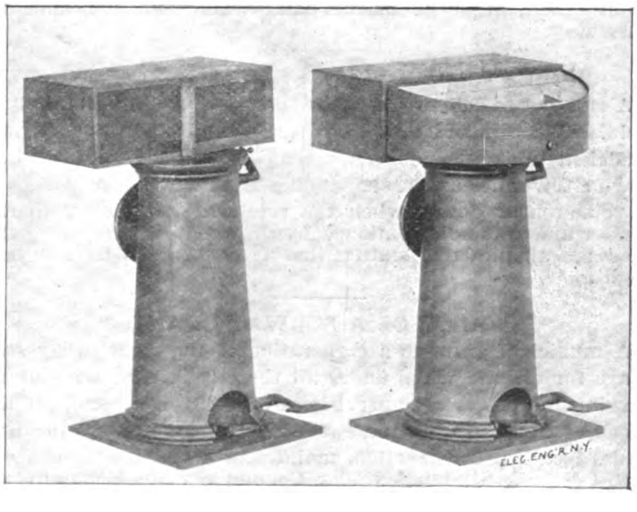
EVERY reader of the newspapers is familiar with the almost daily publication of some bank or business house that has been raided, and from a few hundred to several thousands of dollars extracted therefrom, and in many instances, the faithful cashier or proprietor has surrendered his life in the vain attempt to protect the funds.

To prevent such thefts the device illustrated in the accompanying engravings and known as the cashier's electric safety cabinet, has been constructed. The operation of this machine is both mechanical and electrical; mechanical, during the routine of business; electrical, when the dash is made by robbers upon the bank or business house.

With this cabinet in use, the funds, which have hitherto been placed in drawers and on top of counters, offering a tempting bait for robbers and sneak thieves, will be all placed inside the cash receptacle, which receptacle is always locked by the service mechanism, except when the cashier desires access into the receptacle in the ordinary course of business; by a quick and very convenient manipulation by the foot, the cabinet opens and remains open just so long as the cashier requires it, and at the instant it no longer needs to remain open the cabinet automatically closes and locks by the day locker, and remains locked until necessary to open again.

In the event of a raid, notwithstanding the fact the cabinet is locked by the service mechanism, to place the cabinet and its contents absolutely beyond all power to open, wires are stretched from the base of the cabinet to all points of the bank or business house, with push buttons at every desk in the bank, and all along the inside of the counters of business houses.

When the rush is made by the raiders, and the command is given "Hands up," instantly every hand goes up, and by an employé moving a foot a few inches and touching the push button, the electric current instantly operates the emergency mechanism which locks the machine absolutely. It is then impossible for the burglar to open the machine; neither can he compel any one else to open it, for it cannot be opened until an instrumentality, remote from the bank or business house, is applied. At the instant of the emergency locking, in case of a raid, the electric attachment also disengages and starts ringing a large gong, the sound of which can be heard a long distance, calling help from every direction. Thus it is readily seen that, with the emergency lock in force, rendering the cabinet absolutely closed, the gong sounding, the raider is not going to tarry very long.



Cashier's Safety Drawer.

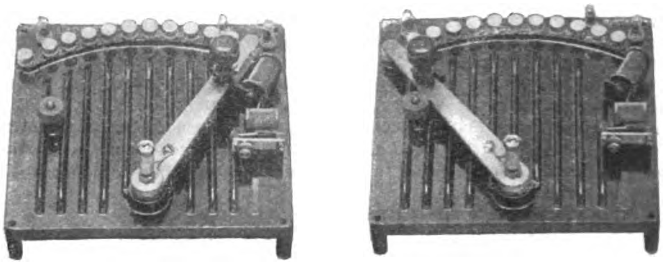
Mr. P. F. King, the well-known inventor of the famous screw door bank safes, that have never been opened by burglars, is the inventor of this cabinet, which, from the knowledge and ingenuity of the inventor, of the needs of the hour, ought to render it an exceedingly valuable and necessary device.

The machine is made in three sizes, weighing from 400 to 700 pounds, and is built by the Cashier's Electric Safety Cabinet Company, of Cleveland, O.

THE WARD LEONARD "D A" MOTOR RHEOSTAT.

THE accompanying engravings represent the latest form of motor rheostat built by the Ward-Leonard Electric Company, of Hoboken, N. J., and patented to Mr. H. Ward Leonard.

This device is known as the "D A," which stands for "double automatic," and in its construction but one lever is employed which is the rheostat contact lever. The rheostat has two controlling magnets. When the lever has been moved so that all the resistance has been gradually cut out and the contact lever stands in its final or short circuit position, it is held in this normal running position, against the action of a retractive spring, by a magnet which is connected directly across the terminals of the motor armature. The contact lever carries a keeper for this magnet, which keeper is brought into contact with the poles of the magnet when the contact lever has been moved to its final position. The holding magnet, it will be observed, is subjected under all normal conditions to a voltage which is the counter e. m. f. of the motor.



Figs. 1 and 2.—The Leonard "D A" Motor Rheostat.

If the supply e. m. f. fails, the counter e. m. f. of the motor rapidly falls and when the motor comes nearly to rest the magnetism of the holding magnet becomes so reduced that the spring which is constantly tending to move the contact lever so as to insert the rheostat resistance, overcomes the magnetic pull and moves the rheostat lever to its starting position, so that if the supply e. m. f. be again restored the motor armature will be protected against excessive current.

The circuit of this holding magnet passes through a contact normally kept closed by a spring. Attached to this spring is a keeper placed near the poles of a magnet whose winding is in series with the armature current. When the current through the motor armature, and hence through this magnet, exceeds a predetermined amount, the magnet attracts the keeper sufficiently to overcome the spring and hence causes the keeper to move toward the magnet poles. This opens the contact in the circuit of the holding magnet, which magnet consequently loses its magnetism and the rheostat contact arm is moved by its retracting spring to its starting position. Thus it will be seen that in case the supply e. m. f. becomes too low or the current through the motor becomes too large, the rheostat lever is automatically moved to its starting position, thus protecting the motor against any possible damage.

It will be observed that the current may fall to zero or reverse without causing the automatic release to operate so long as the current does not exceed the desired maximum. This feature is of vital importance in a rheostat used for an elevator motor or any other kind of motor, which, under certain conditions, temporarily performs as a generator or approximates to that condition.

This D. A. type of rheostat is applicable without any adjustment to any kind of continuous current motor of the horse power and voltage for which the rheostat is made.

In the illustrations, Fig. 1, shows the position of the rheostat when the motor is running full speed, and Fig. 2 with the resistance automatically inserted.

RECENT SALES BY THE WALKER CO,

The Walker Company, Cleveland, O., have recently closed the following contracts: Generators—C. C. Chandler, Chicago, one 100-kilowatt belted; J. C. Hubinger & Co., Keokuk, Ia., one 200-kilowatt belted; Northfoss & Sons, Wadena, Minn., one 75-kilowatt belted; Naugle, Holcomb & Co., Chicago, one 250-kilowatt direct connected, (for Suburban Railway, Chicago), one 400-kilowatt direct connected; Baltimore and Ohio Railroad Company, one 300-kilowatt booster; Foresters building, Toronto, five 50-kilowatt direct connected; Queens Insurance Company building, New York, one 100-kilowatt direct connected and one 50-kilowatt direct connected; Wendell & MacDuffie, New York City, one 75-kilowatt belted; Ludwig Baumann, New York City, two 75-kilowatt direct connected and one 30-kilowatt direct connected; Troy Gas Company, Troy, N. Y., two 150-kilowatt belted; Municipal Gas Company, Albany, N. Y., one 200-kilowatt belted; New York and Staten Island Railroad Company, one 800-kilowatt direct connected; Memphis Street Railway Company, Memphis, one 800-kilowatt direct connected; Columbia Electric Light & Railway Company, one 150-kilowatt belted; J. E. & A. L. Pennock, New York City, two 75-kilowatt direct connected; (for the new St. James building), one 50-kilowatt direct connected and one 25-kilowatt direct connected; Hon. J. W. Hinkley, Poughkeepsie, N. Y., one 50-kilowatt direct connected; Penn Yan, Keuka Park and Branchport Railway Company, two 150-kilowatt belted; Agency Walker Company, Paris, France, one 100-kilowatt belted and two 150-kilowatt belted; Bagnall & Hilles, Yokohama, Japan, two 100-kilowatt belted. In nearly all of the above cases the Walker Company have supplied the necessary switchboard apparatus. Motors and car equipment—C. C. Chandler, Chicago, Ill., four No. 4A double equipments (8 motors); Naugle, Holcomb & Co., Chicago, fourteen No. 10 double equipments (28 motors); North Side Street Railway Company, one No. 3 double equipment (2 motors); D. M. Robbins, Minneapolis, Minn., one No. 5 double equipments (2 motors); Agency Walker Company, Paris, five No. 3 double equipments (10 motors); eighteen single No. 3 equipments (18 motors); twenty-one No. 4A double equipments (42 motors); Bagnall & Hilles, Yokohama, Japan, twelve No. 3 single equipments (12 motors).

G. E. SMALL DIRECT COUPLED ENGINES AND GENERATORS.

THE demand for small direct coupled engines and generators for marine plants meeting the necessary requirements of compactness, light weight, simplicity of construction, freedom from vibration and noise at high speed and perfect regulation as well as durability and low cost, is met by the direct coupled generating sets manufactured by the General Electric Company, of Schenectady.

These sets are built in sizes varying from 2½ kilowatt to 25 kilowatt, and the fact that both engines and generators are manufactured by one concern is an assurance that the fit and alignment are perfect, the finish uniform and the test thorough.

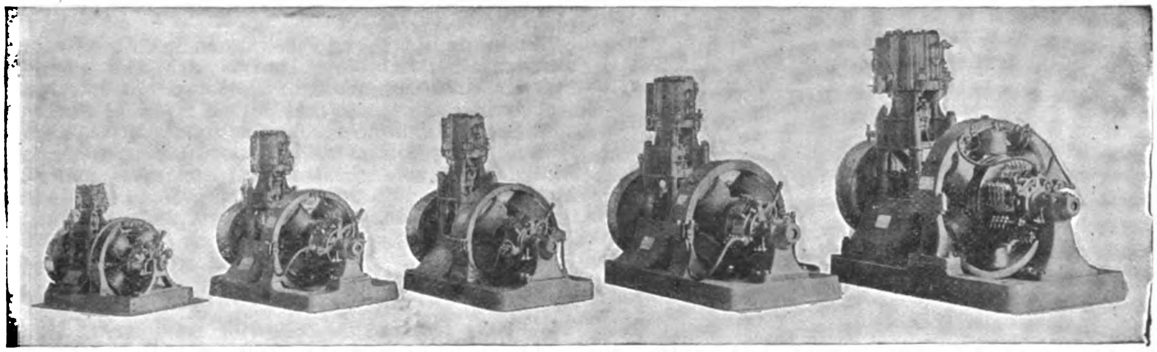
The engine is simple; it has but one valve drive direct from the eccentric pin of the governor. The set is compact; the engine having a short stroke and the armatures being specially wound, both height and length of the sets is reduced to a minimum. The engine bed is lengthened carries the generator, and although the appearance is somewhat massive, the bed is so carefully cored out that without sacrifice of stability the weight has been brought down to about one pound to 3½ watts.

Special attention has been given to the engine parts, to the end that the machine may run with perfect smoothness and regularity. The bearings are self-aligning and self-oiling. The coupling between the armature shaft and engine crank is a split sleeve, which allows of easy removal of the armature. The governor is compact with but few moving parts, which can give practically no trouble or wear out. The 4 kilowatt, 8 kilowatt and 20 kilowatt sets have double cylinder engines; the 2½ kilowatt, 7 kilowatt, 10 kilowatt, 15 kilowatt and 25 kilowatt have single cylinder engines.

All of the generators are four-pole 110 volt machines with the exception of the 25 kilowatt generator which has six poles and a full load voltage of 125 volts. The greatest floor space occupied is 30 in. x 47 x 68 in. high. The generators combine all the well known features of the General Electric machines, and the rating given to each has been calculated on a most conservative basis. Our illustration shows a full line of single cylinder sets—2½ kilowatts, 7 kilowatts, 10 kilowatts, 15 kilowatts and 25 kilowatts.

That the single cylinder engines are economical is exemplified by the fact that they show as low as 28 pounds of water per indicated horse-power hour non-condensing, and 23.5 pounds per indicated horse-power hour condensing, using steam at an initial pressure of 80 pounds just as it comes from its boiler without superheating or making any allowances for entrainment. These results have been reached by a series of tests in which the water has been accurately measured.

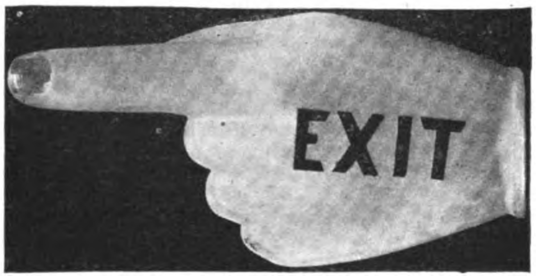
Sets below 10 kilowatt capacity are of course somewhat less efficient, but they compare favorably with engines representing the best practice.



G. E. SMALL MARINE GENERATING UNITS.

THE "GLAD HAND."

THIS is the appropriate designation which has been given to the excellent specialty, the Davis indicating globes, just brought out by the Phoenix Glass Company, of 42 Murray street, New York. Its object is so apparent that it scarcely requires explanation. The hand is 11 inches long and is designed to slip over an incandescent lamp, thus making a most effective guide in hotels, theatres and public buildings generally. These globes are made in opal, ruby or flesh tints with clear letters, showing words such as "fire escape," "stairs," "office," "elevator," etc. There ought to be a big demand for this fetching—or rather, pointing—device.



THE GLAD HAND.

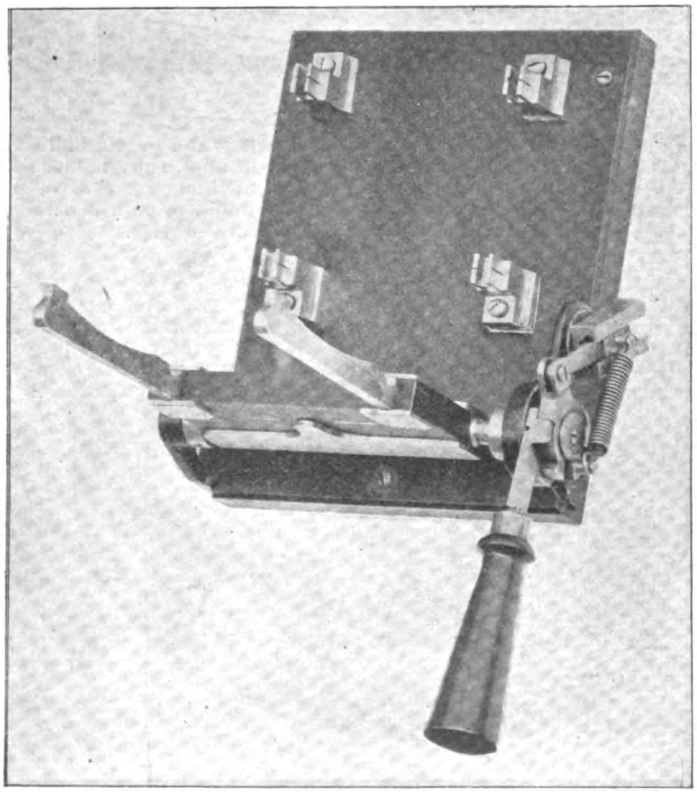
"THE TOOL CATALOGUE."

IF one were asked for a manual, dictionary and encyclopædia of modern American tool practice, the very best answer would be found in the opinion of a great many people, in the magnificent publication of Montgomery & Company, 105 Fulton street, New York City, called "The Tool Catalogue." As a matter of fact it is a fitting companion to Appleton's Cylopædia of Modern Machinery, doing for tools what that standard work has done for machines; and presenting the state of the tool art with a fullness, clearness and accuracy that is little short of marvelous. The book is 10½ in. x 7½ in., has 710 pages, and contains over 3,000 illustrations. An admirable method has been adopted to make this book universally available by those interested. In linen cover it is sent on receipt of 35 cents, and in a handsome cloth binding, in a box, express paid, on receipt of one dollar. This charge is refunded on the first purchase amounting to over $10 and a discount sheet is sent with each book. To specify even the carefully descriptive data and tables in this book is impossible, but it may suffice to say that there is no tool necessary in the electrical factory or repair shop that is not listed and illustrated in detail, and that there are innumerable things given that are needed in electrical line construction, pipe work, cable laying, and interior installation in general. Montgomery & Company enjoy already a good electrical trade, and the possession of this wonderful book—a perfect mine of information—will certainly tend to the more economical management of electrical work of all kinds, by the persons who deal with them.

AN INSTANTANEOUS "MAKE AND BREAK" SAFETY KNIFE SWITCH.

THE Hope Electrical Appliance Company, of Providence, R. I., has just put on the market a very ingenious double pole knife switch, which is claimed to be the only instantaneous "make and break" knife switch now on the market,—a claim conceded by prominent electricians and insurance inspectors who have made most careful examination of it.

We illustrate in the accompanying engraving a style adapted to 500 volt circuits, which has a rated carrying capacity of 50 amperes. The mechanism moving the switch consists of a link motion operated by a handle, which puts in tension a coiled steel spring connected to the axis on which the blades revolve. As soon as the spring is brought to the maximum tension, the slightest further movement of the handle starts the blades, and they are immediately thrown open. The same operation in a reverse direction instantly closes the switch. The action is positive and all four contacts are broken at exactly the same time. This is a very important feature. When the switch is in a normal position, either open or closed, the spring is under no tension whatever. If by any chance it should become broken it does not destroy the quick make and break action.



AN INSTANTANEOUS "MAKE AND BREAK" SAFETY KNIFE SWITCH.

The wearing parts are of drop forged steel having a machine finish. The blades, which are securely riveted to a block of fibre, are of the highest grade of rolled Lake Superior copper and the contact edges are carefully milled to size. The same metal is put in the brushes, which are of ample size to provide sufficient carrying capacity. Brass composition of the highest conductivity is used in the construction of the posts that have milled slots into which the brushes are securely wedged and riveted.

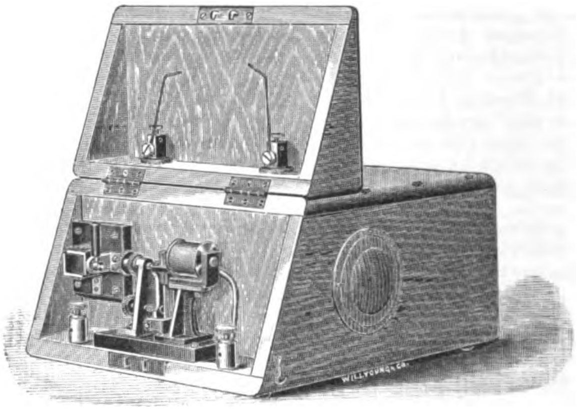
The switch is made with the utmost care in order to secure an easy working of the parts and special attention is given to the accurate alignment of the blades and brushes. Since the switch is operated only by the action of the handle, it can be set in a sufficiently high position to prevent injury or an accidental short circuit of the blades and they can never be thrown out of line by careless handling. The position of the handle at the lower corner of the switch eliminates any danger to the operator, which is especially desirable on high voltage circuits.

The Hope Electric Appliance Company has given special attention to standardizing all the parts so that any becoming broken can be easily replaced. The switch is mounted on a marbelized slate base, and with the high polish presents a very pleasing and attractive appearance. It is made in sizes to carry 25, 50, 75 or 100 amperes for circuits of any voltage.

THE "W-S" PORTABLE INDUCTION COIL FOR X-RAY WORK.

WE illustrate in the accompanying engraving a portable X-ray induction coil recently devised by Messrs. Willyoung & Co., of Philadelphia. The advantage of this coil consists in the fact that it can readily be carried from place to place, being constructed specially for such service.

This coil, as well as all other forms now made by Messrs. Willyoung & Co., is equipped with the new "Ideal" automatic interrupter, reversing switch, and adjustable discharge points, as shown. The entire instrument is mounted in a portable oak case with outside dimensions 14 x 12 x 6½ inches, weighing less than 25 pounds. It is provided with lock and key and heavy metal handle. The spark length of this coil is from four and one-half to five inches, and such discharge can readily be obtained from two cells of storage battery. With such combination and a Bowdoin focus tube of proper exhaustion, practically any X-ray work at present possible can be accomplished.



THE "W. S." PORTABLE X-RAY COIL.

The outfit is especially recommended for "bedside" service and traveling exhibitors, but is also well adapted to office practice. An equipment of this sort, but of larger size, has just been ordered by the Marine Hospital Service to be included in the exhibit which it will make at the Tennessee Centennial Exposition. Mr. James G. Biddle, 910 Drexel building, Philadelphia, sole agent for all apparatus manufactured by Messrs. Willyoung & Co., will be glad to supply further particulars in regard to the "W-S" Portable Induction Coil or other X-ray specialties of the same class.

PEERLESS RUBBER MFG. CO.

We have received the following from Mr. C. H. Dale, president and general manager of the Peerless Rubber Manufacturing Company of 18 Warren street, New York:

Discharged and ex-employés of this company are making false claims as to the founding of this company and the manufacture of its goods. For the benefit of the public we will say that this company was founded in the year 1872 by Charles Foster, Jr., and Henry S. Winans, who associated with themselves as superintendent Mr. John H. Deming, who has had entire charge of the manufacturing department. Mr. Deming has been with this company continuously since 1872, and is at present our general superintendent. He has had thirty-four years' continuous experience in the manufacture of fine mechanical rubber goods. This long experience places Mr. Deming in the front rank of manufacturers. We believe him to be without a peer.

Rainbow packing was suggested by a prominent merchant to C. H. Dale, then general sales agent, and with all other goods made by this company was introduced to the trade solely by Mr. Dale; and Mr. John H. Deming is the only man who has ever manufactured Rainbow packing, and is the only man who knows how. We would also say that Mr. Deming is the only superintendent this company has employed, or had in its employ as superintendent, since it was founded in 1872. All other claims are false.

CARD GENERATOR AND MOTOR INSTALLATIONS.

The Cleveland Ship-Building Company have awarded contract to the Card Electric Company, of Mansfield, O., for the entire electrical equipment for their new ship-building yards and establishment, which will be located at Lorain, O. The electrical apparatus covered in this contract calls for the following: One 100-kilowatt 240-volt direct-connected generator, at speed of 250 r. p. m.; one 40-kilowatt 240-volt belted generator, and twenty-six motors, varying in size from 2 up to and including 40 horse power. These motors are to be used in various sections or departments of their works, for driving machinery of different kinds. In this equipment of motors there will be two of 30 horse-power capacity, to be used for operating two large bending rolls, etc., the total equipment aggregating 500 horse-power. The Card Company say that there are only two electrical manufacturers in the United States besides them that were in position to manufacture and furnish all of the apparatus called for in their specifications, owing to the design and various sized motors which could be adapted for their special use. This is said to be the largest contract of the kind that has been let by one corporation in a long time.

In addition to the above recent orders have been received by the Card Company for the following: One 30-kilowatt direct-connected generator to Thos. McGraw, to be installed in McGraw building, Detroit, Mich.; one 50-kilowatt direct-connected generator, Mechanical Rubber Company, Cleveland, O.; two 10-horse-power motors, with automatic controller for operating elevators, to the Edmonds Elevator Company, Cleveland, O.; one 100-kilowatt direct-connected generator to the Ohio and Pennsylvania Coal Company, Salineville, O.; one 10-horse-power motor to M. A. Bradley, Cleveland. O.; two 10-horse-power motors to Wolverine Manufacturing Company, Detroit, Mich.; one 100-kilowatt belt-driven generator, Monongah Coal and Coke Company, Monongah, W. Va.; one 65-kilowatt belt-driven generator, Jeffrey Manufacturing Company, Columbus, O.; three 25-horse-power motors to H. J. Heinz Co., Allegheny, Pa.; one 11-kilowatt belt-driven generator, Union City (Tenn.) Ice Company, Union City; one 50-kilowatt belt-driven generator and switchboard, Wm. Metcalf, Pittsburg, Pa.; one 20-horse-power motor, Mansfield (O.) News; one 25-kilowatt belt-driven generator, Oak Ridge Hotel, Green Springs, O.; one 10-horse-power motor, Stewart, Howe & May, Cleveland, O.; two 100-kilowatt belt-driven generators, one 67-horse-power and two 30-horse-power motors, to the Raton Coal and Coke Company, Raton, New Mexico.

NEW YORK OFFICES OF THE WALKER CO.

The general sales office of the Walker Company, formerly at 253 Broadway, will be located in the new building on the northwest corner of Wall and Nassau streets, New York City, after May 1, 1897. The Walker Company have taken a whole floor in this new building. Increased business has necessitated these large and more centrally located quarters. The Walker Company are to be congratulated for their enterprise which is indicated by this change of location, and for the success which has rendered an increase of accommodations unavoidable.

POPULARITY OF THE "STANDARD" AIR BRAKES FOR STREET CARS.

The Standard Air-Brakes Company closed contracts with the Dighton, Somerset and Swansea Street Railway Company, of Taunton, Mass., the Commonwealth Street Railway Company, of Boston, Mass., and through their foreign agents, for air-brakes for the continent. The company is also supplying to the Pennsylvania State College, Department of Electrical Engineering, for use on its experimental line, which has been built to teach the students practically, a complete working outfit showing the operation of the "Standard" system.

We quote the following from "The Morning Herald" of February 19, 1897, Sydney, N. S. W.: "A trial departmental trip was made over the tramway extension recently completed, to the waters of Mosmann's Bay, yesterday morning. It was in every way a success. One of the new motor cars left the sheds at Ridge street shortly after 9 a. m., and was taken over the whole route, going up and down the hill from the bay two or three times, everything working smoothly. A second car made a similar trip in the afternoon with great success. The motor cars are of an improved pattern and much more powerful than those at present in use. The cars are fitted with air-brakes (provided with pressure gauges) from the works of the Standard Air-Brake Company of New York." This tramway was opened for traffic on the 1st of March. The grades on this route rise as high as 7.69 per cent.

ADVERTISERS' HINTS

MESSRS. H. B. COHO & COMPANY, the New York agents for the Eddy Electric Manufacturing Company, have removed their office to the St. Paul Building, 220 Broadway, New York, where they will be glad to see their friends.

THE OHIO STORAGE BATTERY COMPANY, 59 Wade Building, Cleveland, Ohio, make a battery for horseless carriage service. They are represented in New York by Machado & Roller, 203 Broadway, New York.

FELTEN & GUILLEAUME, Carlswerk, Mulheim on Rhine, Germany, manufacture single, concentric and biconcentric electric light cables of any section for both alternating and direct currents up to the highest tensions.

BROWNLEE & COMPANY, Detroit, Mich., make some very practical remarks on the selection of poles. The stock they carry embraces poles of every size as well as cross arms.

KEYSTONE ELECTRICAL INSTRUMENT COMPANY are advertising their polarity indicator and detector galvanometer which indicates the polarity of light and power mains on two or three-wire circuits, and also polarity of dynamos and batteries. The price is $2.50, and further information may be obtained by addressing them at Ninth street and Montgomery avenue, Philadelphia.

THE AMERICAN ELECTRIC HEATING CORPORATION, Boston, say universal commendation is the result of presenting to a large number of engineers the "Universal" enamel rheostat. They claim for it all the good points.

THE RIKER ELECTRIC MOTOR COMPANY, 45 York street, Brooklyn, N. Y., have brought out a fan motor which takes but ¼ ampere at 110 volts on full speed. It is of the iron clad type and presents a very neat appearance.

PETEREIT-WEHRLE MANUFACTURING COMPANY, manufacturers of novelties in brass turning, screws, cocks, gas and electric fittings, have removed to 140 Sullivan street, near West Houston street, New York.

MR. H. B. COX, of the Cox Thermo Electric Company, is now in this city with a view to establishing an American agency for the sale of the Cox thermo generators. Temporary quarters have been secured at 126 Liberty street, where machines are on exhibition and may be purchased.

L. T. WEISS, 286 Graham street, Brooklyn, N. Y., is advertising the Weiss drill case, which was recently described in our columns. It is arranged to show every drill it contains at a glance, is a perfect drill gauge in itself which can never be lost and tells what drill to use for any tap. A circular may be obtained giving full information.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., present some interesting figures for the consideration of central station managers.

THE HOPE ELECTRIC APPLIANCE COMPANY, Providence, R. I., are supplying make and break safety knife switches of all voltages. These switches have been approved by the National Board of Fire Underwriters.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, represent the Standard Paint Company and carry in stock a full line of the P. & B. specialties.

THE STANDARD UNDERGROUND CABLE COMPANY have removed their New York office to 18 Cortlandt street.

THE PACIFIC ELECTRIC COMPANY, La Crosse, Wis., are introducing a standard for incandescent lamps which should be cordially welcomed by readers. The lamp is placed in the top of the shade so that the full candle power is reflected on the page at the same time screening all direct rays from the eyes.

MONTGOMERY & COMPANY, 105 Fulton street, New York, have just issued a catalogue of tools containing 710 p.p. and over 3,000 illustrations. They say it may well be called an encyclopædia of tools, as it contains everything conceivable in that line.

THE MAGNOLIA METAL COMPANY, 267 West street, New York, the manufacturers of the world-famous "Magnolia" anti-friction metal, will send a 15-inch brass-edged rule to any engineer sending three cents in stamps and mentioning this paper.

THE PHOENIX GLASS COMPANY, Pittsburg and New York, are selling a style of globe which must prove very useful. It is made in the shape of an index hand to fit over an ordinary incandescent lamp, and in it is blown in red letters the name of the place indicated, as office, stairs, etc.

THE SCOTT & JANNEY ELECTRIC AND MANUFACTURING COMPANY, Filbert street, Philadelphia, are now ready to take contracts for long distance railways, from fifty to one hundred miles single or double track, which they will operate from one power station by their single-phase alternating current railway apparatus.

NEW YORK NOTES.

MR. ELMER P. MORRIS is now comfortably settled in his new quarters at 15 Cortlandt street, and is having remarkably good business in his specialties. Mr. Morris is paying particular attention at present to export business and has just sent a large consignment of Keystone instruments and Cutter circuit breakers to Mexico, besides having some nice orders for general electric lighting supplies for South America.

BI-METALLIC ELECTRIC TRANSMISSION COMPANY will on and after May 1 be located at 121 Liberty street, New York City, to which address all communications should be sent.

H. B. COHO & CO. have removed to new offices in the St. Paul building, Broadway, opposite postoffice, and have recently added to the list of machinery which they handle the Warren alternator and the Diamond transformer. Business in the old reliable Eddy motors and dynamos continues good.

JOHNSON & MORTON.—The business of Nightingale, Johnson & Co., electrical engineers and contractors, 26 and 28 Catherine street, Utica, N. Y., will after this date be carried on under the firm name of Johnson & Morton, Mr. Nightingale retiring from the business. The old firm has met with gratifying success in contracting work and also in the manufacturing of special junction boxes and switchboards, and the new firm will carry on the same work, making every endeavor to give entire satisfaction to customers. Added machinery has been placed in the shop so that the firm is now equipped to do a general electrical repairing business.

JAMES S. BARRON & COMPANY, Hudson and Duane streets, New York, are now comfortably settled in their new quarters. The offices of the Electrical Department are on the second floor, where they will be glad to meet any of their friends and discuss business to mutual advantage. They make a specialty of Eclipse telephone booths and John Weldon's hand-made climbers.

WESTERN NOTES

THE CHICAGO INSULATED WIRE COMPANY have removed their offices from 153 Lake street, Chicago, to 152-154 Lake street, where their new premises are situated exactly opposite to the old quarters which they have just vacated.

MR. H. B. CROUSE, of the Crouse-Hinds Electric Company, Syracuse, N. Y., made a business trip to Chicago recently. Mr. Crouse states that his concern find business much improved, and are pushing the sale of their make of switches, switchboards, panel boards, the Syracuse changeable electric headlights, and other electrical specialties.

MR. J. R. CRAVATH, who for some time has served most creditably as the electrical editor of the "Street Railway Review," of Chicago, and is the very active secretary of the Chicago Electrical Association, has gone into business for himself to push his new recorder, which keeps tab on each motorman's consumption of current, and checks excessive use. His new headquarters will be Room 825 Monadnock Building, Chicago.

FOREST CITY ELECTRIC COMPANY, Cleveland, O., have issued a dainty and pithy brochure on rail bonding and the merits of their "protected rail bond," which consists of coils of flattened copper wire attached under the fish plates or angle irons.

THE ELECTRIC APPLIANCE COMPANY, Chicago, are introducing a new electrical soldering iron, which they are ready to guarantee is an electrical and commercial success. They have given it a very extensive test, and stand ready to guarantee the results.

MR. A. W. KILBOURNE has taken the general agency of the Ohio Storage Battery Company of Cleveland, and will have his headquarters at the Wade Building in that city.

SAN FRANCISCO, CAL.—Articles of incorporation of the John M. Klein Electrical Works have been filed with the County Clerk. The capital stock is $50,000, of which $2,700 has been subscribed by the following directors: John M. Klein, Charles W. Nevin, Harry A. Sayles, John T. Stone and John W. Felt.

NEWPORT, IND.—Mr. Wm. Rheuby, chairman of the Electric Light Committee, desires to communicate with responsible parties with a view to the installation of an electric light plant in the town of Newport, Ind.

BIDS WANTED BY ASTORIA, ORE.

The city of Astoria, Ore., is in the market for a 60-light arc plant, 2,000 candle-power lamps, to be run by the city's water plant.

MECHANICAL

THE PRINCIPLES AND CONSTRUCTION OF WATER WHEELS.—I.[1]

BY W. E. WINES.

THE importance of the water wheel as a prime mover may be appreciated from a consideration of its extensive use at the present day and the almost unlimited water power awaiting development. In 1880 there was employed in the United States a total of about 3,500,000 horse power, of which approximately one-third was derived from water and two-thirds from steam. The application of electricity to long-distance power transmission, and the improvement in the design and efficiency of water wheels have no doubt, during the last sixteen years, greatly increased that proportion of the total power derived from water. A few plants in this country and abroad may be cited as examples. The Tivoli station which supplies the city of Rome, Italy, with current for lighting, utilizes about 2,000 horse power; at Lauffen, Germany, are placed Pelton wheels developing about 1,000 horse power; the well-known Pomona (Cal.) plant is operated by Pelton wheels, aggregating about 1,000 horse power; thirteen miles north of Portland, Ore., on the Willamete River, are water falls capable of delivering from 200,000 to 250,000 horse power, and work has been started on a plant which, when completed, will utilize Victor turbines of about 13,000 horse power; the Niagara Falls Hydraulic Power and Manufacturing Company are at work on a plant which when completed will contain Leffel turbines capable of furnishing 7,000 horse power; mention must also be made of the gigantic undertaking at Niagara, this installation being designed to develop ultimately over 125,000 horse power.

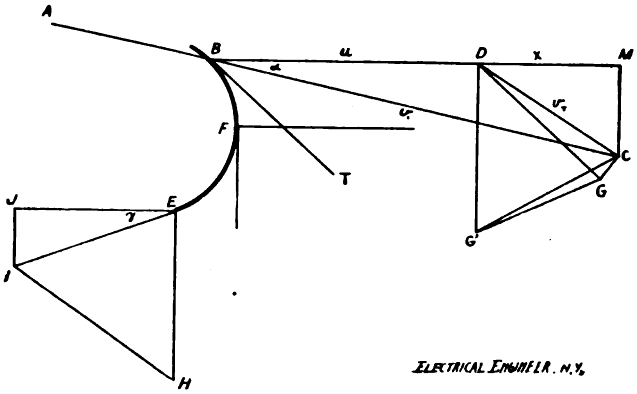

FIG. 1.

Notwithstanding that these plants, a small fraction of the whole, are capable of generating an immense amount of power, still, when it is remembered that the water power of the United States alone is estimated at 200,000,000 horse power, it is evident that the water wheel has a vast field of usefulness before it, and also that it is needless to fear the consequences of the exhaustion of our fuel supply.

Before proceeding to any detailed description or discussion of the different classes of water wheels it will be necessary to lay down a few fundamental principles relative to the efficiency of water wheels in general and to the action of a jet of water upon a vane.

If M is the mass of the water passing through the wheel per second, and if its velocity when entering is $v_1 = \sqrt{2gh}$, the energy supplied per second is $\frac{1}{2} mv^2 = mgh$. The losses in the wheel may be divided into two classes: First those due to the transformation of energy into heat caused by the foaming and eddying of the water, friction on rough surfaces, etc.; second, those due to the velocity v with which the water reaches the level of the tail race. The loss due to the first of these causes may be represented by mgh', h' being the equivalent loss of head; the loss due to the second cause is evidently $\frac{1}{2} mv^2$. Hence the energy per second delivered by the wheel is

$$mgh - mgh^1 - \frac{mv^2}{2}$$

and the efficiency is

$$\frac{m\left(gh - gh - \frac{v^2}{2}\right)}{mgh} = 1 - \frac{h^1}{h} - \left(\frac{v}{v_1}\right)^2.$$

This expression[2] gives the efficiency of the wheel considered solely as a hydraulic motor and takes no account of the losses of energy due to mechanical causes; it is applicable in modified forms to all classes of water wheels and shows that the efficiency will become unity only when $h' = 0$ and $v = 0$. That is, the design should be such that no loss of energy occurs due to the flow of the water through the wheel, and that when the water leaves the wheel it should have zero velocity with reference to the earth.

When a fluid stream strikes a smooth plane surface[3] it is not reflected, as a solid would be, but spreads out into a sheet and flows over the surface with its velocity changed in direction but unaltered in magnitude, this change in direction giving rise to a pressure called the impulse. If the surface be curved, as in the accompanying diagram, Fig. 1, the velocity in the direction of motion is not entirely destroyed until the point F is reached and the whole effect up to this point is due to impulse alone, and is precisely the same as if the jet had impinged upon a plane surface and been instantly deflected. After passing the point F the water continues to flow along the surface, leaving at the point E in the direction E I, the velocity being unaltered in magnitude but still further changed in direction. This added change in the direction of flow produces a pressure on the surface due to the reaction of the water. Hence the energy imparted to the surface may be divided into two parts, viz., that due to impulse and that due to reaction.

If M denotes the mass of water striking the surface per second, x the velocity of the jet relative to the surface, and u the velocity of the surface, the energy due to impulse imparted per second to the surface is mxu; this is apparent since mx is the momentum imparted to the surface in unit time, which is the force acting upon it, and u is the distance through which this force acts in one second. Similarly the work done by reaction may be represented by mx_1u where x is the velocity imparted to the jet in a direction opposite to the motion. The total energy W imparted to the surface is evidently the sum of these two.

$$\therefore W = \underline{mxu} + \underline{mx_1u} = \underline{m^1xu} + \underline{x_1u.}$$

If, on leaving the surface, the water has zero velocity with reference to the earth x_1 is evidently equal to $-u$ and the efficiency of the system is unity.

If the surface be plane, $x_1 = 0$, the entire effect is due to impulse and $W = mxu$; if the velocity of the jet in the direction of motion of the surface equals the velocity of the surface $x = 0$ and the whole effect is due to reaction, $\therefore W = mx_1u$.

These three cases

$$\begin{array}{ll} W = m(xu + x_1u) & \text{impulse and reaction.} \\ W = mxu & \text{impulse.} \\ W = mx_1u & \text{reaction.} \end{array}$$

explain the whole theory of the action of water wheels except those cases in which the weight of the water is caused to do work, and the only change needed is the addition of a term mgh in the expression for work.

In nearly, if not quite, all water wheels of modern construction one or more jets of water are made to impinge upon curved vanes or buckets, the water doing work by both impulse and reaction; hence it will be necessary to an intelligent understanding of the correct design and action of water wheels to investigate a little more in detail the action of a jet of water upon a moving vane.

Let B F E, Fig. 1, represent a curved vane having a velocity of translation u represented in magnitude and direction by BD, and suppose that a jet of water, or other incompressible fluid, having velocity v_1, represented in magnitude and direction of BC strikes the vane at B. Then $DC = v$ is the velocity of the jet with reference to the vane, and x is the component of v^r in the direction of motion of the vane. As soon as the jet reaches B it is deflected in the direction of BT the tangent at B; drawing D G parallel to B T and equal to $D\,C = v_r$ we obtain C G as the instantaneous deviation at the moment of impact. When the jet reaches the point F its motion is perpendicular to that of the surface, and is represented by D G′ drawn equal to v_r and perpendicular to B D. C G′ represents the deviation suffered by the jet during its motion from B to F and its component in the direction of u is $x = v_1 \cos a - u$.

---

[1] Read before the Technical Society of the Armour Institute, Chicago.

[2] The above is from Prof. Merriman's "Treatise on Hydraulics."

[3] The following is adopted from "Turbine Wheels," by Prof. W. P. Trowbridge.

Since the velocity of the jet in the direction of u is wholly destroyed at the point F the effect up to this point is due to impulse alone and the work done on the vane is, as shown before,

$$mxu = m (v_1 \cos a - u) u.$$

After passing F the jet flows over the surface F E and leaves the vane in the direction E I. Drawing E H equal and parallel to D G′ and E I equal to vr, H I represents the change in velocity between F and E, and its component in the direction of u is $EJ = x_1 = EI \cos \gamma = v_r \cos \gamma$. This change in the direction of the jet produces the pressure of reaction and the work due to the reaction is

$$mx_1u = (mv_r \cos \gamma) u.$$

The total work done by the jet due to both impulses and reaction is

$$m (xu + x_1u) = m [xu + (v_r \cos \gamma) u]$$

If $\gamma = o$ the work of reaction is v_ru and the total work is $m (xu + v_ru)$. This is a maximum when $u = v_r$ i. e., when B D = D C. Making this substitution the total work is

$$m (xu + u^2)$$

From the geometry of the figure when B D = D C, we have $BD . DM + BD^2 = \frac{BC^2}{2}$, or $xu + u^2 = \frac{v_1^2}{2}$, and $m (xu + u^2) = \frac{v_1^2}{2}$.

The left hand member of this equation is the work done and the right hand member is the total energy of the impinging water; since these two are equal the efficiency is unity. It is well to notice that this is the case only when $v_r =$ and $z = o$. If z is a very small angle the efficiency may easily be shown to be $1 - \frac{1}{4} \left(\frac{\sin^2 \gamma}{\cos^2 a}\right)$ and it is apparent that this is increased by making a and γ very small.

Since in all wheels the vanes move not in straight lines, as assumed above, but rotate about the axis of the wheel the analysis given above is not applicable directly to any form of water wheel, but the fundamental principle to be borne in mind has been set forth, viz., that to obtain an efficiency of unity both the impulse and reaction of the water must be utilized. This point cannot be too strongly emphasized. It has been overlooked by such authorities as Weisbach and Rankine, who insist that the velocity of the wheel vanes and jet should be equal to avoid what they call shock, but which in reality causes the loss of the impulse action of the water. The honor of correcting this error and building turbines which utilized both the impulsive and reactive effects of the water belongs to two Americans, Uriah A. Boyden and James B. Francis, whose improvements have been universally accepted and followed, at least in this country.

POWER TRANSMISSION

ELECTRIC TRANSMISSION AND THE PACIFIC COAST CLIMATE

BY L. M. HANCOCK, Chief Electrician, Nevada County Electric Power Co.

During the discussion of Dr. Duncan's inaugural address on the "Present Status of the Transmission and Distribution of Electrical Energy," before the American Institute of Electrical Engineers, some one remarked, evidently without the knowledge of the conditions, that "the success of power transmission on the Pacific coast was due to the mild climate."

It is not always mild, balmy summer in the whole of California, which, on the contrary, has anything one could ask for, from a parched desert to a glacier. The wires of the Nevada County Electric Power Company are run at right angles to the ridges and canyons through a foot hill district not low enough to be free from snow nor high enough to have dry snow. The average rainfall is about 40 inches per year, and the snow fall about the same, while for a single twenty-four hours, since the plant has been in operation, there has fallen 4.64 inches of rain and 24 inches of snow, to say nothing of numerous and heavy thunder storms.

On the night of March 5, 1897, there was a fall of 24 inches of very wet snow, and as a result on the morning of the 6th, out of 100 telephones in Nevada City, 21 were in service, and in Grass Valley out of 75 telephones, 7 were in service. Our service was interrupted several hours during the daytime of the 6th, mainly on account of the broken and grounded telephone lines; we had but one wire broken on our new lines.

The rainfall, as recorded at Nevada City for 1896, was 69.37 inches. On April 6, 1896, 3.36 inches; on November 24, 1896, 3.78 inches; while during twelve hours of the night of March 27, 1897, 2.32 inches.

A Pacific Coast Winter Scene.

The plant commenced giving commercial service February 5, 1896. During the tewnty-four hours of January 4, 1895, 6 inches of rain fell. The most extraordinary weather conditions recorded, occurred during the winter of 1889 and 1890; up to February 22, 1890, there had fallen 5 feet of snow on a level and the next day 5 inches of rain fell, giving about as trying conditions as one would care to experience. True, we have not encountered anything so severe as yet, but there is no telling when we will.

We have already encountered about as severe atmospheric electrical disturbances as are common in the Eastern States; we have been shut down completely several times on account of damage done by lightning and have to be as well protected from its discharges as the best of Eastern practice requires.

The accompanying view was taken in Nevada City just after a wet snow had fallen this winter.

THE PERFORMANCE OF THE SPRAGUE ELECTRIC ELEVATORS IN THE MINNEAPOLIS CITY HALL AND COUNTY COURT HOUSE.

BY FRANK J. SPRAGUE.

One of the elevator contracts which, perhaps, has caused more bitterness among, and met with more opposition from, the hydraulic companies than any other, is the one which was awarded to the Sprague Electric Elevator Company over a year ago for equipping the Minneapolis City Hall and County Court House with electric elevators. The combination of hydraulic interests, during the competition for this contract, used every possible means, fair and unfair, to prevent the award, but it remained for one of the most prominent of the Western companies to be especially bitter.

Many unaccountable and unusual troubles have been experienced with the plant since the installation; test after test was made, and finally one by an electrical engineer, who, at the same time, is reported to have sent a report, which was for the private information of the Committee of the City Hall and Court House, to newspapers for publication. Since this report was made, the character of which was manifest on the face of it, extracts have been sent anonymously to architects and engineers throughout the United States.

The Sprague Electric Elevator Company realizing the necessity for thoroughly investigating and exposing the methods under which this plant was operated, took the necessary steps to have the machines inspected and readjusted. A competent engineer was sent to Minneapolis, and the plant was by him put in perfect condition, and the incompetency, to say the least, and the apparent animus, of the engineer and his associates were absolutely demonstrated, with the result that the engineer in charge was dismissed and a successor appointed, since which time there has been no trouble, and the installation, instead of being a source of irritation and correspondence, is spoken of in the Minneapolis "Journal" of March 16, 1897, as follows:

"County Commissioner Ed J. Conroy returned from New York yesterday after quite an extended trip through Washington, New York and Boston. During his trip, Conroy took especial pains to inspect the electric elevators placed in New York buildings by the Sprague Electric Elevator Company. In every instance the elevators were working admirably, without any of the tangible evidences of inefficiency which, during all of last year, followed the working of the elevators here. Since Electrician Rosenbusch has been here, however, the elevators in the Court House have been doing satisfactory service, and Engineer William Robertson speaks highly of their efficiency and work."

In addition to the foregoing, it has the further endorsement of an independent committee who were employed by the commissioners to thoroughly test the machines. The full report of the committee is given below. Its conclusions are so well defined and positive that despite the outrageous treatment to which the machines have been subjected, their performance under rigid test fully satisfied the City Hall and County Court House Commissioners of their full compliance with all the extreme guarantees made for them.

TO THE HONORABLE BOARD OF COURT HOUSE AND COUNTY COMMISSIONERS, HENNEPIN COUNTY, MINNESOTA.

Gentlemen:—Your committee being employed by you December 26, 1896, to test the engines, storage battery and electric elevators, begs leave to supplement their previous reports on Court House machinery with the following report of tests made upon the electric elevators in the same building. The instruments used were Weston ammeter and voltmeters, Schaeffer & Budenberg tachometer, Thomson recording wattmeter and Fairbanks scales. The instruments were all tested and known to be correct or to have ascertained constants. The cars and counter-weights of all the elevators were accurately weighed.

The guarantee made by the elevator contractor was that each elevator should lift a live load of 2,500 pounds at a rate of speed of 350 feet per minute, exclusive of counter-weight with a potential of 110 volts at the motor terminal; the electrical horse-power to lift the live load of 2,500 pounds at the rate of speed of 350 feet per minute is guaranteed not to exceed 40 horse-power with a down speed of 250 feet per minute with only the operator in the car.

Each car was underbalanced 797 pounds; there were three (3) tests made of No. 1 elevator under varying conditions of load, to ascertain the efficiency under the different loads, the average results being as follows:

Screw Elevator No. 1, Test 1.

Weight in car, live load	750	lbs.
Weight in excess of counterbalance	1,547	"
Average speed of car	386	
Average volts at motor	108.7	
Average amperes	199.8	
Average electrical horse-power	29.1	
Theoretical horse-power	18.1	
Efficiency from motor terminal	62.2%	

Screw Elevator No. 1, Test 2, Guarantee Load.

Weight in car, live load	1,703	lbs.
Weight in excess of counterbalance	2,500	"
Average speed of car	352.3	
Average volts at motor	109	
Average amperes	265.5	
Average electrical horse-power	40.4	
Theoretical horse-power	26.7	
Efficiency from motor terminal	66%	

Elevator No. 1, Test 3.

Weight in car, live load	2,500	lbs.
Weight in excess of counterbalance	3,297	"
Average speed of car	351	
Average volts at motor	112.5	
Average amperes	351.5	
Average electrical horse-power	53	
Theoretical horse-power	35.	
Efficiency from motor terminal	66%	

Screw Elevator No. 2, Guarantee Load.

Weight in car, live load	1,703	lbs.
Weight in excess of counterbalance	2,500	"
Average speed of car	355	
Average volts at motor	111	
Average amperes	256.5	
Average electrical horse-power	38.1	
Theoretical horse-power	26.9	
Efficiency from motor terminal	70%	

From the above figures it is seen that the efficiency and capacity of the screw elevators are fully up to the guarantee, their speed being from 2 to 10 per cent. above guarantee; the average electrical horse-power of both elevators 39.5 horse-power.

All instruments were read simultaneously when the car was in the middle of hoistway and at full speed.

These screw elevators were taken apart and thrust plate and nut on screw examined and found in first-class condition. The safety brake was then taken off and the car allowed to drop down to ascertain with what velocity the car would drop; but the speed obtained was but slightly above normal, showing that it is impossible to injure any one should the brake fail. It is the opinion of your committee that the construction of these elevators is good, ample provision being made for all wearing parts and safety devices; the nut on screw being hardened will not wear, the screw being the only part of the machine to wear out. This can be replaced at small expense.

WORM GEAR ELEVATOR.

The guarantee for this elevator is to have a capacity to lift a live load of 2,500 pounds in the car exclusive of counterweights or weight of car at 200 feet per minute with a potential of 110 volts at motor terminal, to have a down speed of 200 feet per minute with only the operator in the car. The electrical horse-power to lift the live load of 2,500 pounds at the rate of speed of 200 feet per minute is guaranteed not to exceed 35 horse-power. The car was overbalanced 321 pounds.

The average results are given in the following table:

Weight in car, live load	2,841	lbs.
Weight in excess of counterbalance	2,520	"
Average speed of car	216.	
Average volts at motor	98.5	
Average amperes	210.6	
Electrical horse-power	27.8	
Theoretical horse-power	16.4	
Efficiency from motor terminal	59%	

The above figures show that this elevator more than fullfils the guarantee, the speed being about 8 per cent. above requirement. With a load of 2,841 pounds in the car the elevator responded quickly in both up and down trips. This load equals 18 people of 150 pounds average weight. The worm gear of this elavtor is of the latest improved type and seems to show no signs of wear, ample provision being made for safety devices.

In order to determine the actual cost of operating the three elevators a Thomson recording wattmeter was connected into the elevator service wires and a continuous record was obtained for the energy used by these, the results were as follows:

Total number of kilowatt hours used for three elevators in nine days:

Kilowatt hours (9 days)	850
Kilowatt hours (1 day)	94.4
Cost to run 3 elevators per day	$4.72
Cost to run 1 elevator per day	$1.57

These figures are based on the regular motor rate of 10 cents per kilowatt hour charged by the Minneapolis General Electric Company and a reduction of 50 per cent. on bills of $250 and over per month. At the rate of 94.4 kilowatt hours per day that were used, there would be used 2,832 kilowatt hours for 30 days. At 10 cents per kilowatt hour this would come to $283.20 per month, 50 per cent. off, $141.60 per month for three elevators. This is remarkably low considering the work they are doing.

The wattmeter was then put on to the two screw elevators only, and reading taken for six days. The total number of kilowatt hours used were as follows:

Kilowatt hours used (6 days)	433
Kilowatt hours used (1 day)	72.1
Kilowatt hours used (30 days)	2,165
Cost to run 2 elevators for 30 days	$108.25
Cost to run 1 elevator for 1 day	$1.80

The wattmeter was then put on the Prison elevator for 10 days and reading taken each day.

Kilowatt hours used (10 days)	366
Kilowatt hours used (1 day)	36.6
Kilowatt hours used (30 days)	1,098
Cost to run Prison elevator for 30 days	$54.90
Cost to run Prison elevator for 1 day	$1.83

The wattmeter was put in the circuit of the three elevators January 7, at 7 a. m., and taken out January 16, at 6 p. m.; then put on to the two screw elevators January 18, 7 a. m. and taken out January 23, at 6 p. m.; then put into the circuit of the worm gear elevator January 27, at 7 a. m., and taken out February 6, at 6 p. m. Readings were taken each day at 7 a. m. and 6 p. m.

A. HARVEY,
J. S. KUPFER.

PROF. GEORGE FORBES ON NILE POWER.

Professor Forbes, who has just returned to Cairo from Wady Halfa, expresses a highly favorable opinion about utilizing the power of the cataracts of the Nile for generating electricity, and considers the general circumstances of Egypt exceptionally well adapted for its use as motive power. Irrigation could be extended as well as cheapened by the saving in cattle, and especially in coal, which becomes enormously dear in Upper Egypt, owing to the expenses of transport from Alexandria. He considers that the cataract power would be available all the year round for working the railway, cotton-ginning mills, sugar factories, irrigation machines, etc., also that it could be supplied over distances of several score miles at a cost much below that of coal. He will, in September, make a complete survey and present the government with a project for utilizing the electricity to be generated at the Nile cataracts.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—IX.

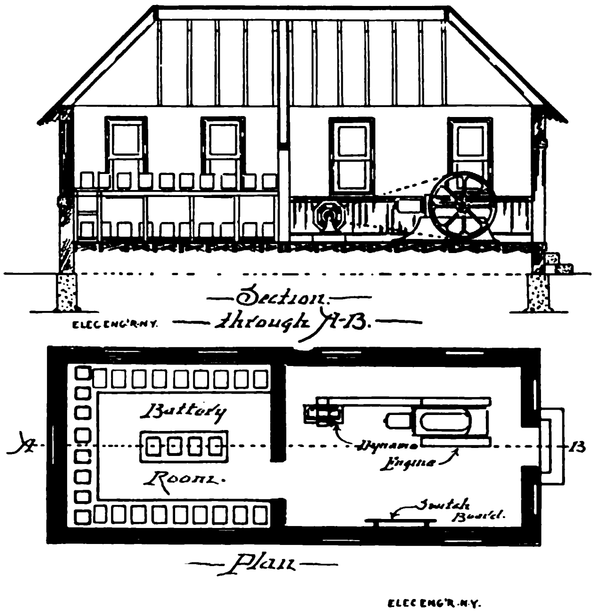
APPLICATION OF STORAGE BATTERIES TO ISOLATED PLANTS.—Continued.

BY JOSEPH APPLETON. (Copyright, 1897.)

FIGS. 28, 28A and 28B, illustrate the general arrangement of a model power house for an isolated plant of this description. Figs. 29, 30, 31 and 32 show, respectively, views of a power house, engine and dynamo, battery room and switchboard for private residence plant.

In all storage battery installations, special attention should be given to the switchboard, as the success of the installation depends largely on being able to control and operate the plant easily and without complication.

A switchboard for this work has features quite different from those found on switchboards for controlling ordinary direct current installations and it is very neccessary that all the details be arranged to suit the conditions, otherwise the flexibility of the system, which is one of its most useful features, may be destroyed.



FIGS. 28 AND 28A.—GENERAL ARRANGEMENT OF MODERN POWER HOUSE FOR ISOLATED STORAGE BATTERY PLANT.

In the second class of isolated plants, the storage battery plays a different part to that described in the previous case. Here the battery acts as an auxiliary to the generating plant, increasing its capacity and efficiency, usually furnishing only a comparatively small portion of the total current instead of the bulk as in the former application.

There are very few isolated plants of this description where a storage battery of suitable capacity will not prove advantageous from both an engineering and financial point of view. Of course the actual conditions of each plant must be carefully examined in order to ascertain what benefit can be derived from the use of a storage battery; there are so many points to be taken into consideration that in order to obtain the best results each situation should be treated as a distinct engineering problem and dealt with accordingly.

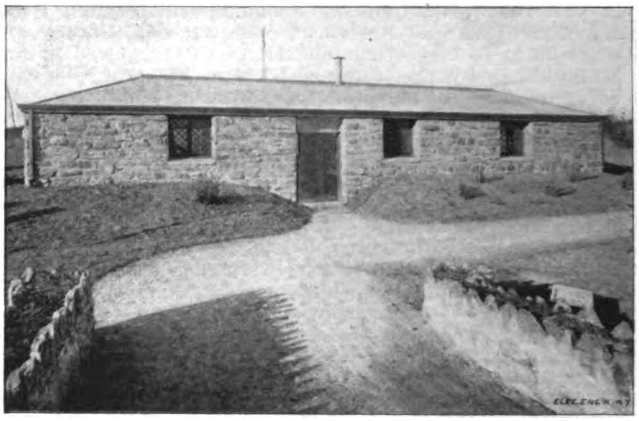


FIG. 29.—POWER HOUSE FOR ISOLATED PLANT.

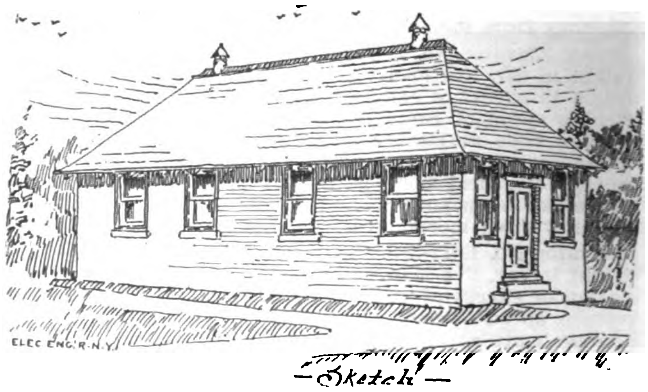
The following are some of the features which have an important bearing on the question: 1. Nature of load and length of duration. 2. Relative proportion of minimum, maximum and average loads. 3. Size of generating units.

The ordinary isolated generating plant as installed in office buildings, large stores, hotels, etc., does not produce current at the lowest price on account of the conditions which exist; the load is variable and liable to sudden fluctuations, all of which have to be provided for in the generating plant. Where electric elevators are used, the conditions are exceedingly bad in this respect. The following are the points in which a storage battery will prove advantageous and economical in an isolated plant:

1. Smaller generating plant required, capacity for the average load instead of maximum load being sufficient.
2. Possibility of operating at point of highest efficiency whatever portion of the generating plant is running, thus effecting large saving in fuel consumption.
3. Possibility of operating both electric elevators and lamps from the same generators with satisfactory results.
4. Greater reliability of service, and better provisions for meeting sudden increase of load due to weather changes, etc.
5. Reduction in length of time during which the generating plant need be run, the battery alone carrying load during hours of light demand.

Having enumerated the points in which a storage battery will effect economies in isolated plants of this class, we will now consider each of them separately.



ELEC. ENG'R. N.Y.
—Sketch—

FIG. 28B.—EXTERIOR VIEW OF MODERN POWER HOUSE FOR ISOLATED STORAGE BATTERY PLANT.

1. A smaller capacity in generating plant can be used where a storage battery forms part of the equipment for the following reasons: In an ordinary isolated plant of this description sufficient generating machinery has to be kept running to meet the maximum demand due to the fluctuations which last only for a few minutes at a time, and may be anywhere from 20 per cent. to 100 per cent. above the average load according to the nature of the installation.

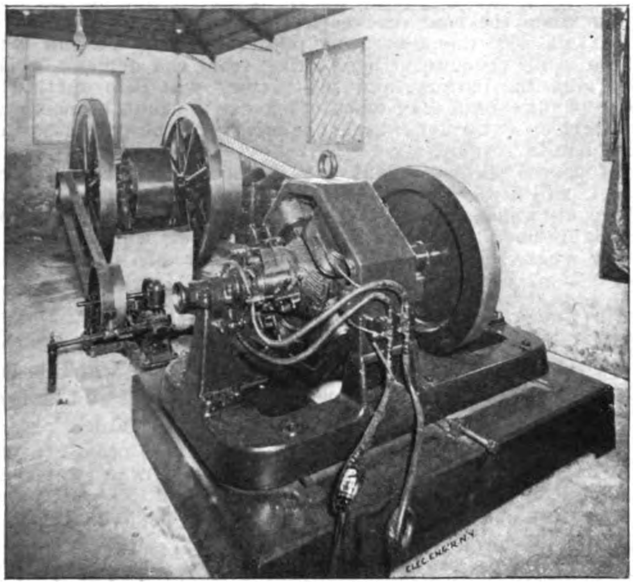


FIG. 30.—ENGINE AND DYNAMO ROOM IN ISOLATED PLANT.

Fig. 33 shows a curve of the fluctuation of current and voltage which exists in elevator service. This curve was plotted from readings taken at ten-second intervals from a modern office building installation. The total variation from minimum to maximum load is enormous, the average load being only 30 per cent. of the maximum. It will be seen that the capacity of the generating plant required for the maximum load is only needed for a very small portion of the time, yet has to be provided, while the load frequently drops to the minimum which is only 5 per cent. of the maximum. Under these conditions the steam consumption of the plant for the output must be very high.

Where a storage battery is used, the conditions are changed entirely; the capacity of the generating plant required is that of the average load, plus the amount of current necessary for charging the battery for the work required of it after the generating plant is shut down, instead of the maximum load. Under these conditions, when a sudden increase in load occurs, the current used during average and minimum load for charging the battery can be diverted and used for supplying the extra demand, thus assisting the generating plant. The adoption of a storage battery in these installations will generally reduce the capacity of generating plant required by one-third to one-half with an accompanying reduction in labor, etc.

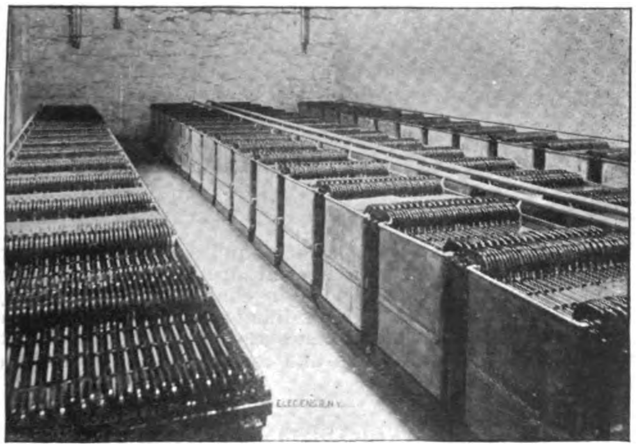

FIG. 31.—BATTERY ROOM IN ISOLATED PLANT.

2. The second point, or operation of generating machinery at higher efficiency when running at a steady and economical, instead of a variable load, follows as a matter of course, on the first. It is not easy to give reliable figures regarding the steam consumption of engines working under variable load as compared with a steady and economical load, as few proper and independent tests of this kind have been made,

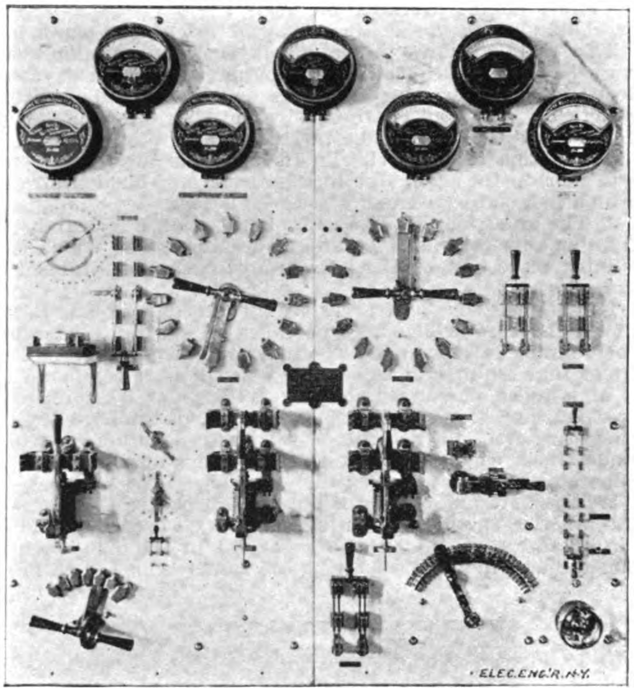

FIG. 32.—SWITCHBOARD FOR ISOLATED PLANT.

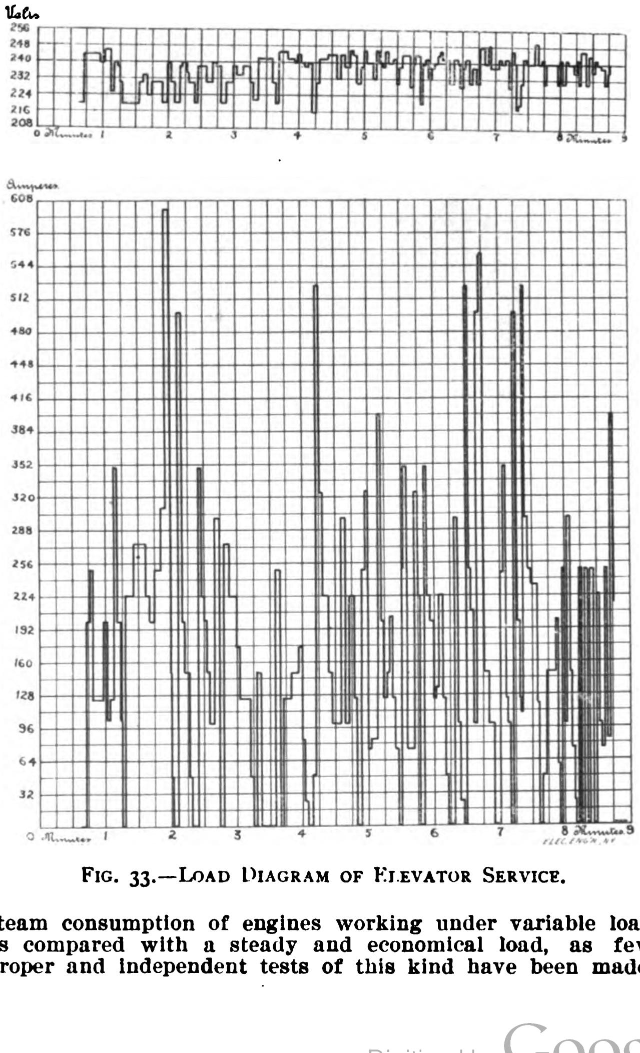

FIG. 33.—LOAD DIAGRAM OF ELEVATOR SERVICE.

but the following may be taken as a fair average of the results obtained in modern isolated plants of this description.

Engine working at full load, or thereabouts, continuously.... 31 lbs. steam per h.-p.
Same engine working on variable load....................57 lbs. steam per h.-p.

This plainly shows the saving in fuel consumption, which may be obtained by taking an engine working at a variable load and altering the conditions so that it will operate at practically full load continuously, this is the function performed by the storage battery.

In addition to the saving in fuel there is the reduced wear and tear on the plant due to the absence of sudden strain to which it is subjected under a variable load.

3. The question of operating both electric elevators and lighting service from the same generator is one which is becoming more important as the use of electric elevators is increasing rapidly.

Elevator service is of necessity an intermittent one in spite of all the care which may be taken to control and regulate the running of elevators. The starting current is from 2 to 3 times that required to hoist, and when it is remembered that a high speed passenger elevator takes 40 or 50 horse-power to hoist, and that in an office building, or similar situation, there are frequently eight or ten such elevators, it will be understood what an effect this service would have on the generators.

Where a storage battery is not used, it is almost universally the practice to run the lighting and elevator service from separate generators; this increases the size of the plant required, and reduces the load factor of the same. It has been proved beyond doubt that with a proper storage battery equipment these two services can be combined and operated from the same generators.

4. The reliability of the lighting and power service in any building open to the public use is of the utmost importance, and should receive the first consideration from those in charge of the plant; nevertheless many instances can be found where in the case of a sudden increase of load due to weather changes the supply has failed partially, if not entirely, and confusion has resulted. In order to prevent this, a reserve must be constantly maintained even though required only once or twice a year. Central stations have found a storage battery the best means of providing this reserve, and the service required from isolated plants of this description is similar though on a smaller scale.

5. The reduction in length of time during which an isolated plant is run means a reduction in expenses in many ways. A storage battery equipment enables the generating plant to be shut down at such times when there is not sufficient load to run it economically, the battery alone carrying the load during hours of light load.

For example: In an office building the period of heavy load occurs for a short time during the morning and a longer period in the afternoon; the interval between these peaks can be utilized for charging the storage battery, thereby maintaining the load on the generating plant fairly uniform throughout the run. The function of the battery is to carry the entire load while the generating plant is shut down, which will be from the time the heavy load goes off in the afternoon until the next morning, also in many cases to assist the generating plant during the short time in the afternoon when the load reaches its maximum.

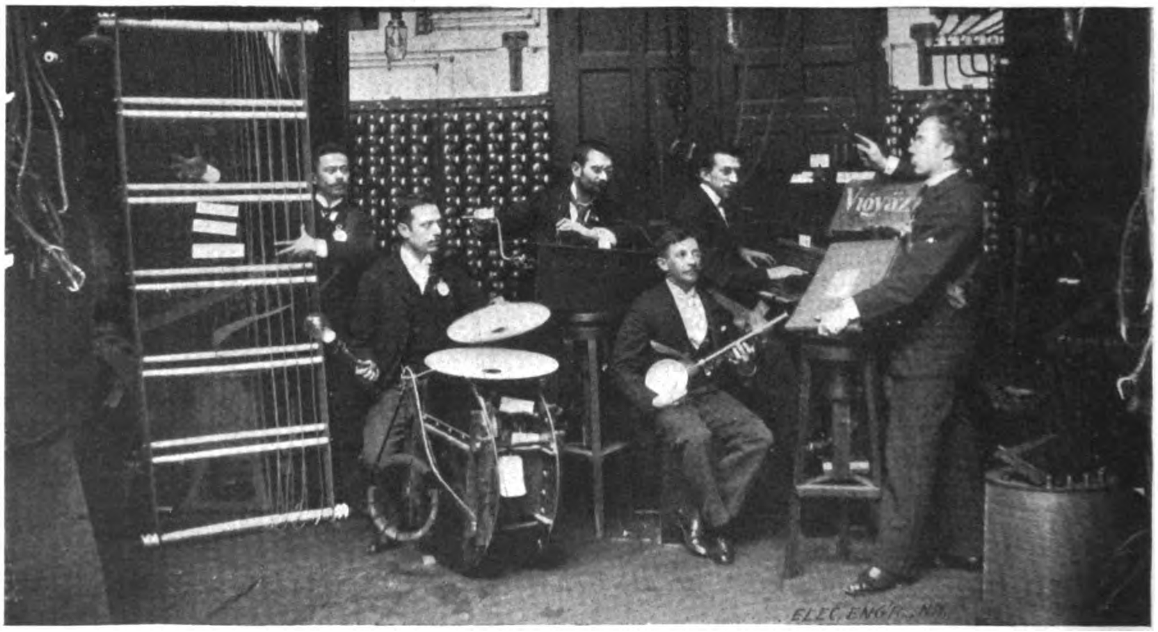
In this way the generating plant need only be run when there is an economical load either from the demand, or for charging the battery, and the battery will help out during time of maximum load when otherwise it would be necessary to start up extra generating machinery for perhaps less than one hour's service.

Of course the conditions vary according to circumstances, but it will always be found in installations of this class that there are times of heavy load, with the intervening periods of light load, and it only requires a little consideration to show where a battery will prove advantageous.

THE ELECTRICAL ORCHESTRA.

THE accompanying engraving represents the first electrical orchestra of its kind ever organized, which is now rehearsing actively at Budapest and, we understand, expects to go on an extensive concert tour in the near future.

The instruments composing this remarkable orchestra consist of a banjo (Cardew voltmeter), a hand organ (wattmeter resistance), a harp (large charging resistance), a triangle (Prony brake), a piano (switchboard with contacts as keys), cymbals (pair of flat lamp shades), and a bass drum (Blathy transformer), beaten by a special drumstick (incandescent lamp). Finally the leader's baton consists of a Leyden jar discharger. This clever bit of humor will no doubt be enjoyed by our readers, and shows that fun can be extracted even from the prosaic tools and apparatus of the electrical engineer.



An Electrical Orchestra.

PIPE ELECTROLYSIS IN DENVER, COL.

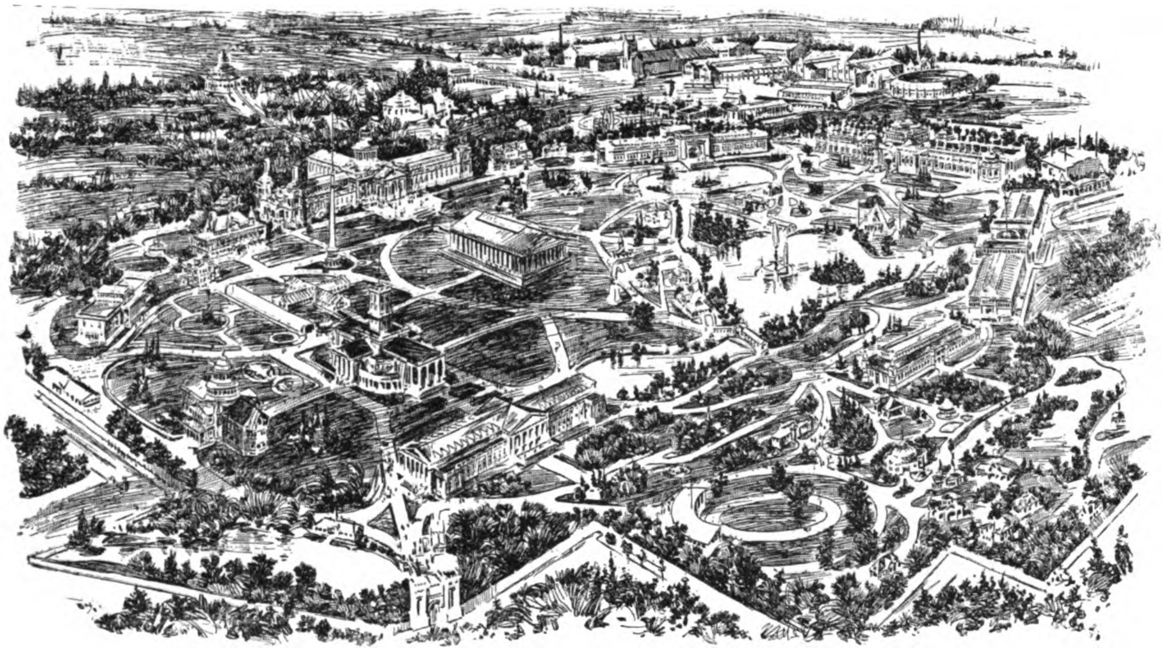
The subject of the destruction of water and gas pipes by electrolysis is just beginning to receive attention in Denver, Colo. Although the extensive systems of electric railways have been in operation for over seven years the effect of the stray currents has been noted only in the last year or so, probably delayed by the dryness of the soil for which that section of the country is noted.

A sufficient number of mysterious breaks in the water pipes have occurred of late to convince the Chief Engineer of the Water Company, Mr. C. P. Allen, that a thorough examination and test is necessary.

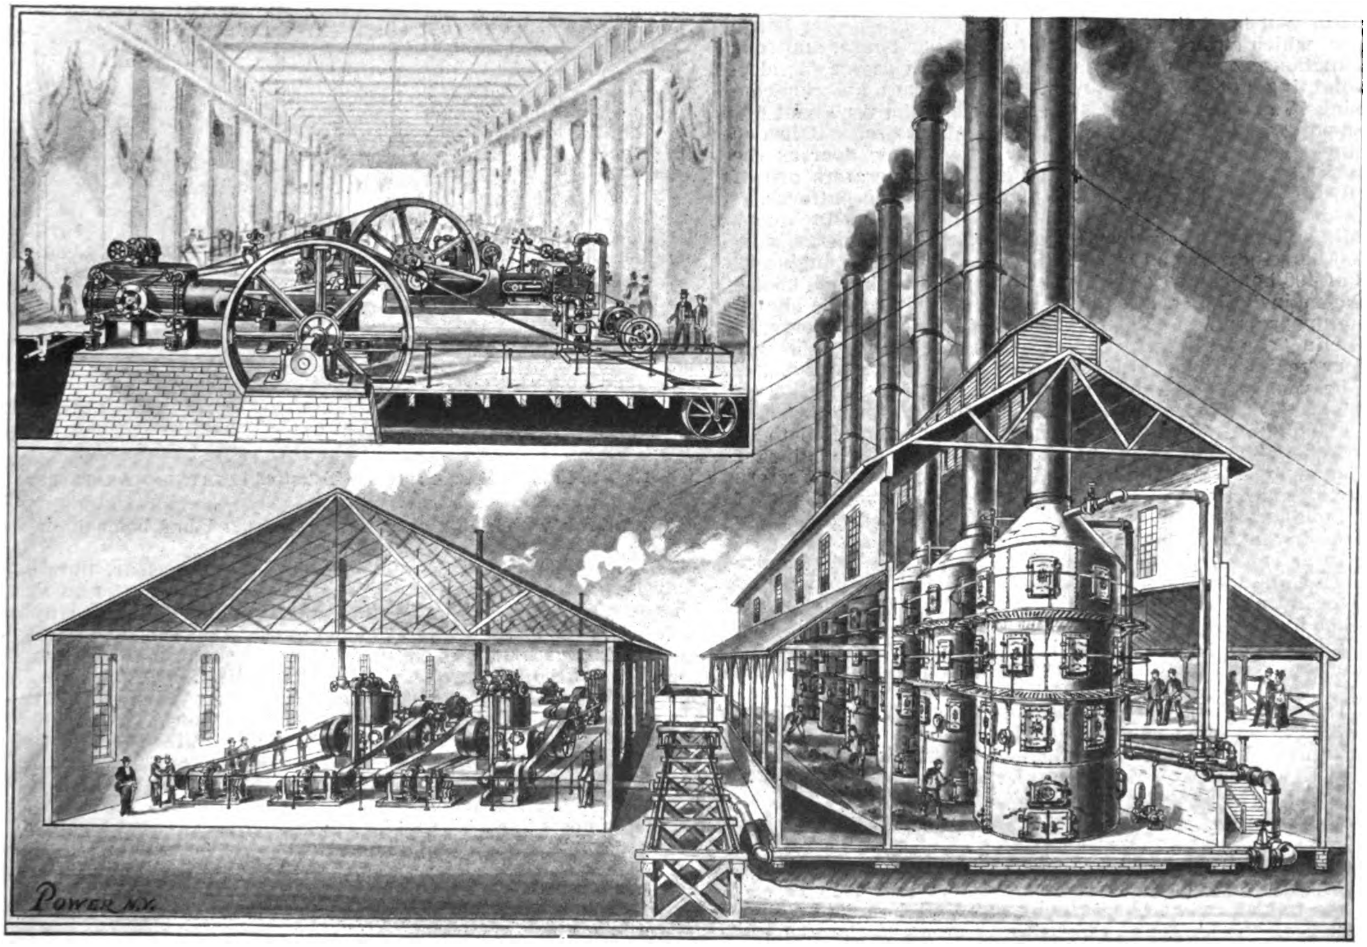
Mr. Lewis Searing, of that city, has been placed in charge of the work for both the water and gas companies, and a very extensive investigation will be conducted.

ELECTRIC POWER PLANT AT THE TENNESSEE CENTENNIAL AND INTERNATIONAL EXPOSITION.

ON May 1 President McKinley, at Washington, pressed the key which started in motion the machinery of the Tennessee Centennial Exposition at Nashville.



BIRDS'-EYE VIEW OF THE TENNESSEE CENTENNIAL AND INTERNATIONAL EXPOSITION, NASHVILLE, TENN.



POWER PLANT OF THE TENNESSEE CENTENNIAL AND INTERNATIONAL EXPOSITION, NASHVILLE, TENN.

Tennessee is the first State to celebrate its centennial in this manner. A tract of two hundred acres of well wooded land on the outskirts of the city, two miles West of the State Capitol, is the site of the exposition. On its picturesque knolls and surrounding its pretty artificial lake, a miniature World's Fair has arisen, and patriotic Tennesseeans already know it as the "Fair White City of the South."

For two years the work has been in progress, and the expenditure of $2,000,000 has wrought wonders in the park. Like their Chicago prototypes, the buildings, most of which are of steel, have all the outward marks of white marble palaces, and are all on a consistent and artistic architectural plan. The exposition is the most important of its kind ever attempted in the South.

THE BUILDINGS.

The Machinery Building is 375 x 138 feet, and somewhat resembles the Propylaeum, in Munich. The Commerce Building measures 591 x 250 feet, and its general style is based on the Corinthian and Ionic orders of the Graeco-Roman. Over the central pavilion a dome rises to the height of 175 feet, from which a most magnificent view of the surrounding country may be obtained. The Agriculture Building is 300 x 200 feet, and the central dome the feature of the design, rises to a height of 100 feet, flanked on either side by three minor domes.

The Children's Building is a most interesting structure and was erected by funds collected solely by the children.

The Negro Building is one of the most attractive in the Exposition group, and has a commanding position on Lake Watauga. It will show the progress of the negro race in America from the old plantation days to the present. The Railroad Exhibits and Terminal Station Building is in the Renaissance style of architecture, and is 100 feet square.

The "Midway Plaisance" at Nashville is called "Vanity Fair."

THE POWER PLANT.

To accommodate the power plant two separate buildings have been erected, views of which are given in the accompanying engravings, for which we are indebted to our esteemed contemporary, "Power." These buildings consist of a boiler and an engine house near the Machinery Building, and in the boiler house, steam will be generated by four 500 horse-power and two 250 horse-power Climax boilers, each with a separate iron stack projecting through the roof. The boiler house has an open balcony extending along the front from which visitors can inspect the general arrangement. The boilers are rented by the Exposition at five dollars per horse-power from the builders, and are erected and taken down at the Exposition's expense. They are constructed to carry 120 pounds pressure. The stoking will be by hand, the coal being brought to the boiler house in cars and dumped in front of the boilers, by means of the chute as shown.

Steam will be delivered to the engines of the power house proper, which stands in the rear of the boiler house, and four Westinghouse compound engines will furnish power for electric lighting and electric power. The engines are non-condensing 18 and 36 x 16 and are expected to deliver about 400 horse-power each. They are belted direct to two, and in one instance three, generators, situated on the same floor as the engines, as shown in our engraving. The generators are of the Brush, Western Electric and General Electric patterns.

The boiler plant will also furnish steam to the Machinery Building proper, where one Hamilton-Corliss engine 24 x 48 of 500 horse-power, and one Lane & Bodley Corliss engine 22 x 48 of 400 horse-power, will furnish power for the line shafts of the main building. These engines are belted as is shown in the upper panel of the engraving, to line shafts underneath the main floor, from which belts are brought up to the machinery to be driven. In some instances, short jack-shafts will be used over the driven machinery, and a variation of speeds will thus be secured. Machinery Hall will also contain a 100 horse-power Weston engine, direct connected to an 80 kilowatt Triumph generator, and one Phœnix engine of 150 horse-power, direct connected to a 100 kilowatt Western Electric generator which will complete the power plant of the Machinery Building. Two 50 kilowatt Wood generators will be driven from the line shaft.

Steam is conveyed to Machinery Hall from the boiler house through a 10-inch pipe at the end of which a small pump and receiver return the condensation of this pipe to the boilers. Another line of 6-inch pipe extends to the fire pumps located in a building at the side of the lake in the exhibition grounds where one Worthington and one Laidlaw, Dunn, Gordon pump furnish ample protection. The boilers are fed by Laidlaw, Dunn, Gordon boiler feed pumps 10 x 6 x 10 and Hancock inspirators also supply each boiler.

The entire department is under the management of Capt. George Reyer, chief of Machinery Department, who is superintendent of the Water Works at Nashville, Tenn.

WHAT HO!

The following query and answer are from the Trenton, N. J., Sunday "Advertiser":

Please tell me what is meant by a "Watt hour," the time by which electricity for illuminating purposes is charged.

UNCLE SAM.

A division of time made by James Watt, the inventor of modern condensing engines. The Watt hour is of about the same length as the standard hour, and is used on electric meters.

SIEMENS & HALSKE NEW HIGH TENSION LIGHTNING ARRESTER.

In a paper read by Mr. H. Goerges before the Berlin Electrotechnical Society, that gentleman described a new form of lightning arrester made by Messrs. Siemens & Halske, of Berlin, and adapted especially for high tension circuits. The lightning arrester is primarily due to a suggestion of Mr. Oelschläger. It is designed to satisfy the conditions that a lightning arrester ought to fill primarily, namely, that it be without self-induction, that any arc formed be automatically extinguished, and, finally, that it leave the arrester in a condition to operate immediately for a succeeding lightning discharge.

As will be seen in Fig. 1, the new arrester consists of two heavy copper wires bent in a peculiar manner, and placed opposite each other. The lower part of each wire is horizontal, then turns up vertically, and then takes an oblique direction with a gentle curve. The wires are carried above and below on cast-iron caps cemented to porcelain insulators, and the horizontal low ends of the wires are inserted in bushings and can be moved in and out, so that the distance between the wires can be regulated. One of these wires is connected to the circuit to be protected and the other to earth.

When lightning strikes the circuit the arc which follows travels upward and is extinguished in a few seconds. The experiments undertaken in the factory of Messrs. Siemens & Halske show that this new form of lightning arrester works the better the higher the potential. At low potentials the arc is not driven upward with certainty, and as a result the lowest limit for which this arrester can be used has been determined at 2,000 volts.

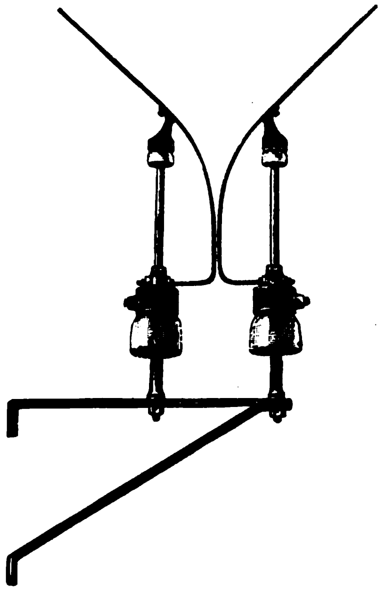


Fig. 1.—Siemens & Halske High Tension Lightning Arrester.

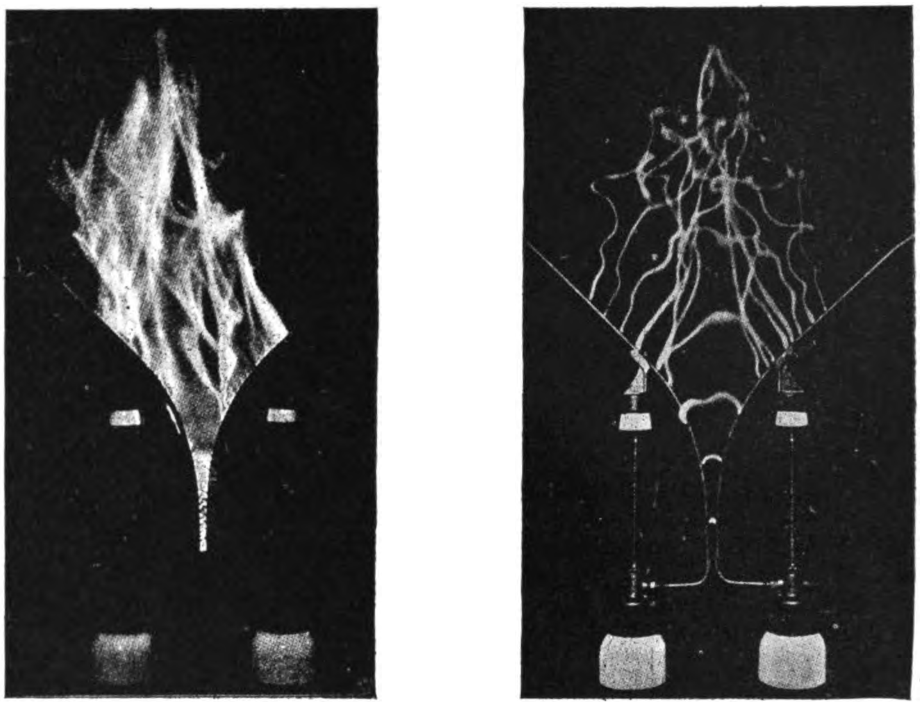
The reason for this phenomenon is not quite clear, but it may be due to the properties of the arc, which are different at high tensions from those at low. For example, it is noteworthy that the wires are scarcely attacked by the high tension arc. In one test about 100 short circuits were made with a 10,000 volt machine of 100 kilowatt capacity driven by a 50 h. p. motor. A 30,000 watt transformer furnished the high potential. At the conclusion of this test no particular burns were discernible on the wires, which gradually attained a black, roughened surface. From this the conclusion may be drawn that those spots at which the arc starts are not highly heated by high tension currents. The case is different, however, with low potentials. In the latter case burns are very readily produced and the arc remains stationary at these points.

The reproductions, Figs. 2 and 3, show the action of the new arrester. Fig. 2 is a time exposure of about two seconds, during which the arc traveled upward and was extinguished. The alternations of current may be recognized in the engraving, and the time calculated within which the arc was driven up a given distance. Fig. 3 is a reproduction of a photograph taken by means of a rotating disc, having a narrow radial slit. In this way only a few of the many arcs which are blurred in Fig. 2 are visible. They show that at every instant the arc constitutes a thin thread that follows the currents of air in wave-like motions.

The arc may attain considerable magnitude. Experiments were made with the lightning arrester in an installation operating at 8,000 volts. A turbine of 750 h. p. drove a 3-phase machine, the potential of which was raised to 8,500 volts through several large transformers of 200,000 watts capacity. The arc flames rose nearly ten feet in height, but the arc was extinguished in every instance after a short while. During these experiments the turbine was running at half-gate. The arrester was employed in Germany, in an extensive installation, during the whole of last summer, which was particularly remarkable for the occurrence of heavy thunderstorms, the lightning arresters being placed in every case in the open air and without further protection. No rain guard is required if care is taken not to approach the wires too close to each other at the lower ends. In all installations in which a sufficient number of these lightning arresters have been installed not a single case of damage by lightning has been recorded, nor has the arrester itself been damaged sufficiently to make any repairs or renewals necessary.



FIGS. 2 AND 3.—ARC FORMED WITH SIEMENS & HALSKE HIGH TENSION LIGHTNING ARRESTER.

ROENTGEN RAYS

ADJUSTABLE X-RAY FOCUS TUBES.

BY A. A. C. SWINTON.

As all who have had occasion to use X-rays for practical purposes are aware, the penetrative value of the X-rays produced by any given Crookes tube, depends very largely upon the exact degree to which the tube has been exhausted. Further, as is well known, a tube originally exhausted to any particular vacuum, is found in practice to alter its degree of vacuum with age and with use. With tubes of the Jackson focus type, that have been well exhausted in the first instance, the vacuum usually increases the more the tube is used, particularly if sufficient power is employed to heat to redness the platinum anti-cathode. Indeed, it is not unusual for this increase of vacuum to be such that it is eventually found impossible to get any discharge to pass through the tube at all.

Various arrangements have from time to time been suggested and tried for the purpose of regulating the vacuum in tubes. One plan is to keep the tube permanently attached to the mercury pump, so that a little air can be pumped out or a little let in whenever it is found necessary. Another arrangement is to place some material, as, for instance, caustic potash, which is capable of absorbing air and giving it out again when warmed, in a small pocket or annex to the tube, which can be heated by means of a spirit lamp, and the vacuum reduced as occasion requires. This, however, as also the ordinary plan of heating the whole tube by means of a spirit lamp, or Bunsen burner, so as to drive off into the interior of the bulb the gases condensed upon the glass, are at best only make-shift expedients, which, though capable of good effect in the hands of skilled experimenters, are not permanent in their results or adjustable with sufficient accuracy to be really satisfactory. Further, exceedingly minute alterations in vacuum will make all the difference between satisfactory and unsatisfactory results in some of the more difficult cases to which X-rays are now applied.

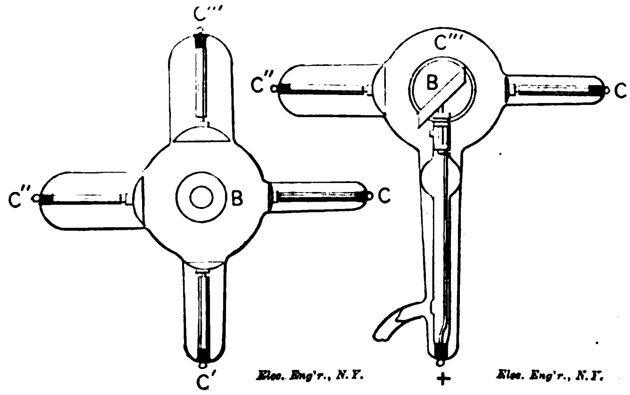
Under these circumstances, the writer has devoted considerable attention to devising a method whereby the penetrative value of the X-rays produced by a focus tube could be easily varied without alteration to the vacuum, and whereby further, the penetrative value of the rays could be maintained constant at any desired degree, in spite of the uncontrollable variations in the vacuum that are found to occur in practice.

A full account of the writer's experiments in this direction will be found in a paper entitled "The Production of X-Rays of Different Penetrative Values," recently read at the Royal Society, but here it is only necessary to mention two of the results obtained, namely, that the penetrative value of the rays for any given degree of vacuum, depends among other things upon the area of the cathode disc, and upon the lineal distance between the cathode and anti-cathode.

Upon these principles the writer has designed two separate forms of adjustable focus tube, Figs. 1 and 2, being two views of one of these tubes, and Fig. 3 a view of the other.

In the form of tube shown in Figs. 1 and 2, advantage is taken of the difference of effect produced by employing cathodes of various sizes. As will be seen from the illustration, the tube is provided with four concave aluminum cathodes, c, c′, c″, c‴, all of the same radius of curvature, namely, .75 inch, but of four different diameters, varying from .5 of an inch in the case of c, to 1.125 inches in the case of c‴. The cathodes are so placed that they all focus on a point in the center of the bulb of the tube, and the inclined anti-cathode disc B is mounted upon a small steel spindle, turning in aluminum sockets, so that the anti-cathode can be easily rotated by tapping the tube, so as to face any one of the four cathodes that it is desired to work with.

The anti-cathode disc B, made of aluminum, is of considerable mass, being in oblique section about .25 of an inch in thickness, cut from an aluminum rod 1 inch in diameter. The cathode rays are not received directly upon the aluminum, but upon the surface of a disc of platinum about .6 inch in diameter, and about .025 inch thickness, tightly wedged and riveted into a shallow circular depression turned out of the face of the aluminum block. The reason for the particular shape of the aluminum portion of the anti-cathode, is to ensure its being balanced in all positions of the tube, so that it should have no tendency to rotate of itself. The object of the general arrangement is to prevent the platinum from attaining an excessive temperature, even when great electrical power is employed, this resulting from the considerable radiating surface of the aluminum, and its considerable mass requiring a less time to heat it up to any high degree.



FIGS. 1 AND 2.

This arrangement makes the tubes take considerably longer to exhaust in the first instance, but renders them much more permanent, as not only is there no danger of melting the platinum, as frequently occurs in the ordinary form of anti-cathode, but also the difficulty experienced with the red hot platinum including the residual gas, and thus increasing the vacuum, is largely done away with, while in addition, the platinum having only one surface exposed, and never getting very hot, the tubes do not blacken so quickly.

As will be seen from the illustration, the anti-cathode is supported in a long double glass tube, through which passes an aluminum connection to the anode terminal. By this method great rigidity and accuracy are attainable, and the anode and cathode terminals are kept well apart.

During the process of exhaustion, it is necessary to make each of the cathodes operative in turn, so as to expel the residual gas, and finally the tube in exhausted to the necessary vacuum to produce X-rays of medium penetrative value, when one of the intermediate sized cathodes is in use. The tube is then sealed off, and afterwards the penetrative value of the rays can be varied at will by turning round the anti-cathode so as to face any one of the cathodes, and making that cathode alone operative. The small cathode gives rays of the highest penetration, and the large cathode, rays of the lowest penetration.

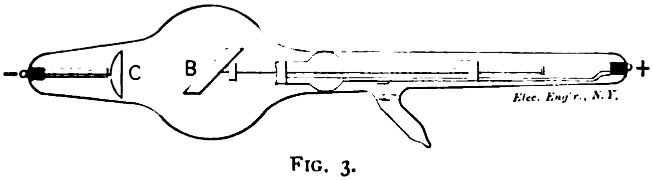


FIG. 3.

With cathodes of the dimensions given, the range is very considerable. It can be diminished or increased by making the cathode more nearly of one size, or the reverse. In place of the rotating anti-cathode, a fixed one may be used of four-sided pyramidical form with a platinum disc let in on each face opposite to each cathode. The anti-cathode terminal need not be used as anode, as when one disc is cathode, the immediately opposite disc may be employed as anode.

The other tube, with which the penetrative value of the rays can be altered by quite a different method, is shown in Fig. 3. In this case the tube is fitted with but a single cathode C, and the anti-cathode B, which is of similar construction to that used in the other tube, is carried upon a steel rod which slides in two aluminum blocks, mounted in a glass tube and connected to the anode terminal. By slightly inclining and shaking the tube the anti-cathode can be made to slide along in the bulb so as to alter the distance between the cathode and the center of the anti-cathode from about one-quarter inch to 3 inches. Stops are provided upon the sliding steel rod to prevent its traveling too far in either direction.

With a tube of this description it is found that the shorter the distance between the cathode and anti-cathode the higher is the penetrative value of the X-rays, and vice versa, so that by simply altering the position of the anti-cathode it is possible both to compensate for variations in vacuum, and also, within limits, to produce X-rays of any desired penetrative value.

The writer is indebted to the assistance of Mr. J. C. M. Stanton and Mr. H. L. Tyson Wolff, who made the tubes illustrated, as also all the earlier tubes with which the original experiments were carried out.

LETTERS TO THE EDITOR

STATION APPARATUS FROM THE MANAGER'S STANDPOINT.

THE examples of the most recently constructed stations given in your paper have shown us the trend of practice to secure economy, efficiency and reliability and have shown us the course we will have to take to keep up with the best practice. While the troubles of most stations are about the same, I think ours have been a little peculiar. Quite all of our trouble has resulted from the peculiar construction of an alternator. It seems to have been designed on purpose not to be "fixed" at the station, but to be sent back to the factory. No. 11 threads; blind connections of the field coils so that the whole machine would have to be dismantled to get at one of the twenty coils to rewind the same; sharp edges on the inside of the field magnets that would cut through any insulation when the centrifugal force is applied; the 200 volts terminals of converters coiled so close together that a short circuit is a dead certainty.

We have rewound coils and coils and eliminated all the defects that ought to have been kept out by the use of a little common sense and commercial honesty at the factory. We paid for it but didn't get it. How I would like to plan a dynamo from the standpoint of the one who has to opreate it and make dividends.

We are getting along very well in spite of the electrical concert. We have learned enough about the business to keep from being cheated and swindled by the new-thing-just-what-you-want man. We wish you great success with your journal, and may it prosper as it deserves. B. C. D.

April 21, 1897.

ARC LIGHT CARBONS AND THE NEW TARIFF.

AFTER reading the letter written by Mr. S. B. Pike on the above subject, I think that in justice to the central station men who desire to have this question debated in a disinterested way, he should have signed the letter not as the secretary of the Edison Illuminating Co. of St. Louis, but for the Phœnix Carbon Co. of St. Louis, whose president I am informed he is. Station men would then at once know what value to place on his rather doubtful arguments in favor of the preposterous rate of duty on imported carbons. From Mr. Pike's letter it appears that no inducements had ever been held out for home talent to furnish a carbon equal to the imported. This is speaking rather slightingly of the home talent, as we all know that we Americans are generally considered as not being slow when an ambition is to be satisfied, quite apart from the fact that a large fortune is in store for the man who succeeds in teaching home manufacturers how to make a carbon that would undoubtedly command the home trade.

Mr. Pike's allegation that foreign carbons have undersold the domestic, contradicts the actual facts quite as much as his statement that this alleged condition has discouraged much experimental work by home talent. Any station man knows that the imported carbon to-day commands a much higher price than the domestic on account of its fine quality, and although I consider myself a good business man, who watches the interests of his station very carefully, I have never yet been able to buy a fine class of imported carbon at anywhere near the price at which the domestic product is sold.

In regard to the second part of his statement, it is a fact, I am told, that at least three of the leading home manufacturers have been experimenting for years at a great expense, and after failing in their efforts, admitted that they would never be able to equal the imported product.

I wish to remind Mr. Pike of an advertisement that appeared in some of the trade papers about two years ago, and in which a certain firm informed the trade that by importing the man from Europe who had made the imported carbon, they had succeeded in making a carbon that would excel any imported article. The central station men have been waiting for this excellent article ever since.

Mr. Pike is, however, particularly unfortunate in his astonishing statement that as soon as the domestic product is adequately protected, the St. Louis companies would look for a reduction in the cost of carbons. By this statement Mr. Pike himself proves that the high protection for which he pleads is not needed by the domestic manufacturer, who—according to his statement—is expected to reduce the cost of carbons to the St. Louis local companies as soon as he secures this protection; and if Mr. Pike had attempted to prove that the present duty of 30 per cent. ad valorem on imported carbons is sufficient protection for the home manufacturer, he could certainly not have done better.

All I asked in by previous letter was that the price paid at present for carbons should not be raised on account of the proposed rate of the Dingley tariff bill, and I am glad to say that Mr. Pike has assisted me materially in inviting the central station men to oppose the measure, which must have the effect of not only raising the price of the imported article, but also of the product of the domestic manufacturer, who naturally pleads for protection in order to get a better price for his goods. ANOTHER CENTRAL STATION MAN.

May 5, 1897.

News and Notes.

THE KEITH ELECTRO-CYANIDE PROCESS.

The process for recovering gold from ores is being exploited by some influential South African men, of whom Mr. Paddon and Mr. Tudhope, of the Johannesburg Consolidated Investment Company, are the chief. Dr. N. S. Keith, the inventor, is an American electrician, who has for several years been connected with the Sandycroft Foundry in England. The process consists of two parts, that may be separately considered: First, the process for dissolving the gold out of the crushed ore, and second, the recovery of the gold from the solution. Dr. Keith's improvement in the dissolving process consists in adding to the solution of potassium cyanide a certain amount of cyanide of mercury. In practice he states that he finds that the best results are obtained when the solvent contains 0.05 per cent. of potassium cyanide and 0.025 per cent. cyanide of mercury. This mixture of cyanides, it is claimed, operates very much faster than the simple potassium cyanide. At present we have no exact figures relating to the rate of solution, but experiments on a practical scale are now being made and will be available shortly.

The process for the recovery of the gold from the solution is an electrolytic one. The gold and the mercury are deposited together upon amalgamated copper plates. The amalgam so deposited is scraped off and the gold recovered by distilling off the mercury in the usual way. The anode is not allowed to dip into the cyanide solution, but is placed in a separate compartment and surrounded with a solution of an alkaline salt, so that the cyanide does not become decomposed. The electro-motive force of the current need not be more than ½ volt and the current density on the depositing surface may be as low as 0.06 ampere per square foot.

ACCIDENTS WITH WIRES.

THE overhead electric wire is responsible for many disasters to life and limb. A long list of tragedies can be credited to this cause. Fatalities are frequent, says the "Age of Steel." An electric wire in its right place is a potent factor in modern business, but when, by the stress of service, time, or weather, it breaks from its holdings, and hangs like a fiery snake over the heads and at the feet of pedestrians, it is as deadly as a cobra in the tropics. It is a serpent of science, when out of its place, as it is one of its best servants when in midair. The "Railroad Gazette," in a recent issue, has given some startling figures of mortalities due to falling wires. In a compilation of accidents, obtained from press reports for the five months from May to September of last year, the following was obtained. As the sources of information were fragmentary and incomplete, the figures given are but an approximation of the total. From falling trolley wires there were 122 accidents; in 11 of these 12 persons were killed, and in 28 cases 31 persons were injured, and in 18 instances 24 horses were killed. Forty accidents occurred from falling electric and telephone wires, in which 9 persons were killed, 27 injured, and 7 horses made into calcined meat. Human fatalities for the period named numbered 21. At the same ratio for a period of twelve months, the death roll would include 50 persons. In contrasting this total of fatalities with those occurring on steam railroads, the "Railroad Gazette" says that for the year 1895 the railway mortuary list included but 38 passengers killed. Thus the deadly wire clearly outclasses the split rail, the misplaced switch, or the broken tie or bridge. It is evident from these facts that some plan for the better protection of human life from falling wires is needed. How best to bring it about may be more or less a problem, but of its urgent necessity there can be no division of opinion. The overhead system, however carefully constructed and secured, cannot, from the very nature of things, be otherwise than a menace to public safety. In many of our cities the lines of wires are thick and numerous as the threads in a spider's web. They outclass the complicated ravel of a full-rigged ship, and in sheer weight alone, at contiguous and intersecting points, are many tons in weight. In heavy winds, or local conflagrations, and under masses of debris or snow, the danger of these overhanging masses of copper and cable is increased. It is, moreover, a fact that, however rigid and close inspection may be, the detection of weakness and the prevention of sudden dislocation are not always possible. Wires will continue to fall and citizens to be electrocuted in spite of all precautions, and the death roll will still employ its copper pen until legislation supervises the deadly scribe. It has thrown its protecting shield over the railway and the mine, and sooner or later it will have a word to say on the perils of the wire.

SMELTING METALLIC ORES IN THE ELECTRIC FURNACE.

ACCORDING to an article in "Le Genie Civil," of Paris, M. Heibling has for some time been engaged in experimenting with the electric furnace, his object being to ascertain how to apply electricity best to the smelting of metallic ores, and especially whether the smelting operation in the electric furnace could not be maintained continuously, as in the blast furnace. He early recognized the fact that the slags resulting from the fusion of the ores were usually poor conductors of electricity, and that their presence in the furnace was very apt to break the electric current and thus put a stop to the operation. He therefore sought to obtain a flux which would be a good conductor, and found that by using a mixture of lime and carbon he could obtain a slag which was a good conductor and would not interrupt the current. Moreover, he found that after separating the metal the slag remaining was not worthless, but was a carbide of calcium, very impure, it is true, but still having some commercial value.

Under the action of the heat of the electric arc a part of the carbon takes up the oxygen in the ore under treatment, while another part combines with the lime and with different contents of the ore, transforming them into carbides, which are fusible and are conductors of electricity. The fused carbides take up and hold the infusible portions of the ore in suspension, while the metal settles in the bottom of the furnace.

In some experiments recently made at Puteaux the mineral treated was chrome-iron ore from Boucau in the Basses-Pyrenees. In treating this without the flux, though a large quantity of electrical energy was expended, he obtained the metal only in the form of irregular strips or ribbons, and these were very brittle, breaking up from their own weight. By adding certain proportions of lime and carbon, however, he obtained from the same weight of mineral, with a smaller expenditure of electrical energy, a greater quantity of metal. Moreover, the metal was ferrochrome and was in the form of a compact lump or ingot; while the carbides which formed the slag or residue from the operation gave nearly 250 liters of acetylene per kilogram.

THE SULTAN.—In a recent sketch of the "Great Assassin," Mr. Stephen Bonsal gives some details of his reading. He says that the Sultan is sick of the Napoleonic literary craze, but that he has lately read two books about Edison and wants more. He adds that the Sultan keeps abreast of modern science and discovery, although "the slaughter of Christians whenever the opportunity permits is part of his duty."

THE OSTRICH BOY, after a hearty meal of nails, screws and other boarding house fare, in Philadelphia, had his stomach X-rayed on April 30 by Dr. A. Goodspeed, of the Pennsylvania University. The repast was revealed in a state of rapid and orderly digestion. The time of exposure was two minutes.

TELEGRAPHIC AND TELEPHONIC SPEED.

SO much has been said on this side of the water of the advanced position taken by European governments in the adoption of machine in place of hand telegraphy that it seems well worth while to inquire what are the facts in the case. This is all the more desirable as a number of schemes have recently been put forward in the United States, with a view to the establishment of machine telegraph systems here. A good opportunity for this comparison is afforded by the records of a telegraphic speed contest which was undertaken in connection with the recent celebration of the 50th anniversary of the introduction of telegraphy in Belgium. This contest is particularly interesting because it compared not only the relative speed of the Morse operator with that of the Hughes apparatus, but also with that of the speed at which messages can be transmitted by telephone.

The first test undertaken was with the Hughes apparatus, and consisted of the transmission of 640 words of plain text in foreign languages, 144 words in a text agreed upon, taken from English and French; 400 cipher words in groups of five and ten each; ten words in secret letters composed of five consonants, and finally a newspaper article of 700 words in French; that is, a total of 1,557 words. The "sledge" of the Hughes apparatus was run at a speed of 144 turns a minute, and the test lasted a little over forty-five minutes. To the time occupied by each contestant there was added 30 seconds for every word omitted, 20 seconds for a deformed word, and 10 seconds when a single letter in a word was altered. The result showed that the winner of the contest accomplished his task in 45 minutes and 12 seconds, which reduces to 2,397 words per hour. This was not considered an exceptional performance as several operators have records equal to that of the victor in the test. Experience has established the fact that a speed approaching to that above mentioned can be maintained for several hours, without excessive fatigue by skillful operators.

The work in the Morse contest consisted of the transmission of 670 words in languages other than the French, comprising a mixture of cipher and clear text. The operators in nearly all cases transmitted without error, and the lowest in the list only lost three dots. In the contest the receivers could neither ask for repetition, nor break. The actual contest commenced at a speed of fifteen words a minute, and towards the end ran up to twenty words a minute. During one hour there were received 1,591 words, containing 7,248 letters, consisting of 7,085 dashes and 11,403 dots; that is, a total of 18,488 signals, which represents five signals or two letters per second. It was difficult to say during how long a time such a speed could be sustained, depending as it did much on the temperaments of the operators. Thus whereas some, after one hour, appeared quite calm, the writing of others, receiving, denoted a marked nervous agitation. In the final test between the two who were originally marked first ex-aequo, one of the two collapsed after one-quarter of an hour's work. The noise of the sounder affected him painfully, and he was no longer able to write, whereas his rival at the end of one and one-half hours was as calm as at the start.

The figures cited above will come as a surprise to many. They show first that the Morse transmision, at least in Belgium, is far less behind the Hughes apparatus in speed than is generally supposed to be the case. Thus, whereas, with the latter system 2,397 words were transmitted in one hour, the Morse apparatus managed to get through 1,591, thus demonstrating an excess for the Hughes apparatus of only 50 per cent.

It is also interesting to compare the Morse figures obtained in Belgium with those reached in the United States. The most recent test of this kind was that of the employes of the Postal Telegraph-Cable Company between New York, Chicago and Pittsburg. In this contest Pittsburg sent to New York during five hours 10,216 words; that is, an average of 2,043 words per hour. This, it will be seen is only 15 per cent. less than the speed obtained with the Hughes apparatus, while on the other hand it exceeds the speed of the Belgium Morse work by over 28 per cent. This showing would seem to indicate the unmistakable superiority of the American telegrapher. Whether the result be due to the physical and mental superiority of the American Morse operator over his Belgian confrère or to the superiority and greater lightness of the American Morse key over the heavy foreign Morse key usually employed, is a question which might well be made the subject of an inquiry. On the other hand the slow speed of the Hughes apparatus is somewhat disappointing. Of course it must be taken into consideration that the Belgium test included considerable cipher work and transmission in foreign languages, but even that, we think, hardly accounts for the differences in speed noted.

But, perhaps, the most interesting event in this contest was the exchange of telegrams by telephone. In this test the French language only was used, and the proper names, numbers and texts of actual telegrams were employed for the purpose, so that the conditions were those of actual practice. The contestants had to observe the same measures of precaution as are employed in their daily work. The number of words received by each during a period of twenty minutes was 368, or at the rate of only 18 words per minute! The deduction made for errors in the case of the victor in the test was seven seconds, and the last on the list had one minute and forty-three seconds charged against him. The two operators classed first in this contest were then put to transmitting by telephone regular newspaper articles, and they succeeded in establishing a record of 38 words a minute. This record was considered remarkable considering not only the circumstances under which it was made, but also on account of the employment of a single receiver applied to the left ear. The Belgian administration is about to diminish the inconveniences of telephone work by putting on such operators four hours per day, in two shifts of two hours each, besides the employment of a telephone which permits the changing of the ear at will.

MR. TESLA ON X-RAY BURNS.

IT may be considered a rule of nature that every beneficent manifestation of force may be accompanied by deleterious effects unless guarded against by suitable precautions, and the Röntgen ray is no exception to the rule. The very earliest experimenters in this field noted a harmful action of the rays on the skin, but of late instances have been reported of serious injury due to so-called X-ray burns. It is probable that the cases mentioned are due more to neglect or improper treatment of the injury than to the original effect of the "burn;" nevertheless, it is eminently desirable that all possible means be adopted for the prevention of the injury to begin with, on the old principle that an ounce of prevention is better than a pound of cure. Mr. Nikola Tesla has doubtless done as much X-ray work as any one, and with apparatus whose sheer power has probably not been exceeded by that of any worker in this field and invariably without harmful results, when certain precautions were taken. The means employed with such good results, and their raison d'être, are described in an interesting communication appearing in our contemporary, The Electrical Review.

For the prevention of X-ray burns Mr. Tesla finds that a chief precaution is to interpose between the bulb and the person a thin sheet of aluminum or aluminum wire gauze, connected to the ground directly or through a condenser. This screen, according to Mr. Tesla, prevents the formation of electro-static streamers, which would otherwise issue from the body, and which have an irritating effect. In the course of his experiments, Mr. Tesla observed, however, that the injurious effects did not seem to diminish gradually with the distance from the terminal, but ceased abruptly. He accounts for this as due to the effect of the ozone generated, and supports this view by the fact that the generation of ozone ceases at a definite distance from the terminal.

But perhaps the most striking fact developed by Mr. Tesla in these investigations is, that bulbs containing platinum electrodes are more injurious that those provided with aluminum electrodes, in support of which assertion he cites a number of experiments.

To sum up, Mr. Tesla advises: 1. The abandonments of bulbs containing platinum. 2. The substitution for them of a properly constructed Lenard tube, containing pure aluminum only. 3. The use of a protecting aluminum screen, as indicated above, or, instead of this, a wet cloth or a layer of fluid. 4. Exposure at no less distance than 14 inches, and preferably to expose longer at a greater distance. As regards other physiological influences of the X-ray, Mr. Tesla records the fact that since he has begun to work with the X-rays his health has been improved and he has been entirely relieved of a troublesome cough; this same effect was observed on another person. He has also observed that when the head is brought close to a powerful tube the effect is similar to that produced when working for some time with a noisy air gap. As the X-ray tube gives forth no sound, Mr. Tesla concludes that the tube produces violent explosions and concussions, which, though they are inaudible, have some effect on the bony structure of the head. Their inaudibility, he explains on the assumption that not air, but some finer medium, is concerned in their propagation. In conclusion, it may be stated that Mr. Tesla still adheres to his oft-expressed opinion, that the X-ray tube when in action emits a stream of small material particles. Some of his experiments would seem to indicate that these particles start from the outer wall of the tube; others again seem to prove that there is an actual penetration of the wall, and, in the case of a thin aluminum window, Mr. Tesla has not the least doubt that some of the finely disintegrated cathodic matter is actually forced through. Mr. Tesla stands practically alone in his advocacy of the corpuscular theory of the Röntgen rays, but his faith in its correctness seems to be growing stronger as time passes and his experiments multiply.

FALSE TEACHERS.

IN his noble sympathy with the poor and the unfortunate, Bishop Potter has, we think, allowed himself to have been led into deep error and the grossest of false teachings, in his recent utterances at the Trinity Church celebrations in this city, when he made a fierce attack on modern machinery and invention. We had thought the church emancipated from such opinions as this: "It is doing away with intelligence in labor. It is turning the laboring man into a simple idiot. Not long ago I visited a large factory in this State and was much impressed with what I saw. The owner proudly showed me around, pointing out the manner in which labor was simplified. I saw a young man sitting before some sort of a large hammer. He sat with his legs crossed and all his work consisted in shoving into an opening in the machinery a small piece of iron. He would turn the metal two or three times, throw it into a large box, and take another piece. That was this man's work, day after day, week after week. No wonder that at night time he drank, gamoled and fought. He had to; otherwise he would go mad. How many of us would stand this and not cry out? Not one of us but would become a striker. Myself among the first." Not only is there an onslaught here on all that human ingenuity and invention have done to lighten the burden of labor, but an accusation is made against the laborer also, to the effect that he is becoming brutalized and degraded by his contact with machinery.

Having delivered himself in this wonderful way, Bishop Potter sought out the finest piece of modern machinery he could find—one of the fast Atlantic steamships—and hastened away to London, thus saving his time at the expense of his consistency; for he ought to have taken the slowest sailing ship afloat. Even that would come under his ban of pernicious machinery, for the whole trouble is the drawing of the line in these matters. The very earliest implements that lift men above barbarism are machines, of a rough kind, it is true, but still machines; and why should we slip back to rank savagery? To save our souls? The impossibility of rolling back the tide of advance is in fact about as plain as the sinfulness of Bishop Potter in urging men to smash things or to go on strike because of the assumed monotony of their calling. Was there no monotony of work before machinery of the modern type came into vogue?

If there is one thing well proved and easy to prove, it is the fact that machinery lightens labor, renders employment more regular, increases wages for the amount of work done, and by the constant shortening of the hours of toil is giving the laborer leisure and variety he never knew before. In New England wages have risen 91 per cent. in fifty years. Bishop Potter in excusing apathy, in teaching that machinery is an evil, and in palliating gross dissipation and vandalism, is a public enemy; and much as we admire frankness in such a man, it is a duty to protest against his unchristian utterances. We trust no electrical inventor will cease his work because of this dark discouragement from one whose Master described the lofty aim of their useful lives when, as the highest expression of his own spiritual mission he said: "Behold! I make all things new."

THEFT OF CURRENT.

INSTANCES of theft of current have become more numerous of late, and there is evidenced a disposition on the part of the courts and local companies to treat electricity as property. At Louisville, Ky., a saloonkeeper was held by the judge recently, on the ground that electricity is valuable property, although the defendant urged that in tapping the electric light wires he had taken nothing of value. A similar case has come up at New Bedford, Mass. The proprietor of a millinery store ordered his Edison lights discontinued and the meter taken out. This was done, but when an employé of the local company went around he noticed that the lights were still burning. An investigation revealed the fact that the connections had been made direct to the street mains again. It would not be hard to decide these cases on their merits, and brush aside the flimsy argument of the German courts that property to be stolen must be a thing filling space. What about copyright, patents and libel suits? They all deal with property that is intangible, whereas electricity can be measured, and, for the matter of that, weighed. Every Edison meter acts on the intrinsic principle of weighing the current consumed.

CARE OF STORAGE BATTERIES.

MR. F. P. SHELDON read a paper recently before some mill men in Boston on electricity for mill purposes, and suggested the use of both motors and storage batteries. Mr. Frank M. Messenger, of Grosvenordale, Conn., said that his experience had been that it required a $1,500 man to take charge of a $500 battery. Other members apparently agreed to this judging from the applause and laughter that greeted the remark. Mr. Clarke replied by telling the story of the man who bought a gold pen from a peddler and after using it a few days returned it with the words: "I don't know what I want of a gold pen; I can't spell any better with it than I could with the common sort." He said with a little study almost any one could learn how to run a battery. Any one who has read Mr. Appleton's recent articles in our pages will note how frequently the plants of batteries are now put in the hands of men who certainly would consider it an unearned increment to be classed as experts at $1,500 a year.

POSTMASTER W. W. CARR, of Philadelphia, is enthusiastic in his praise of the trolley car mail system as carried out on the 600 miles of trolley lines in that city. There are now thirty clerks at work on that service, and he states that the envelopes show by their record a great improvement over the old system of mail transfer by horse and wagon. The pneumatic tube system has been much talked about, but he sees no use for it unless it can handle mail sacks weighing 250 pounds apiece. It seems to us that this is a new field of work for conduit tube trolleys, of the telpher type, and we hope to see them introduced at no distant date. Meantime, the trolley mail car has been a beneficent factor in expediting the delivery of letters in nearly all our large cities, and as Mr. Carr intimates, the public wants more of it.

IT will be noted from our Legal Column, that the U. S. Supreme Court has, in the manner expected, refused to cancel the Berliner patent of 1891, the claims of which broadly control the art of telephony as based on the use of electrodes in constant contact with varying pressure. It is of course well understood that this decision does not sustain the patent on its intrinsic merits, so that the fight for infringement is still ahead, and may be a long one, even resulting in the cancellation of the patent as void. Meantime the position of the American Bell Telephone Company is measurably stronger.

RUMORS were afloat the last few days as to the breaking of the incandescent lamp pool. The story is positively denied in several authoritative quarters. It appears to have its origin in another rumor that one of the lamp companies has gone into strong hands, and that the most will be made of its special features. A letter from Cleveland informs us that the Adams-Bagnall Company have sold out their incandescent lamp factory to Fort Wayne interests, and that the Adams-Bagnall Company, reorganized, will hereafter make only arc lamps.

A VERY satisfactory test was made on Monday of the new third-rail system on the New England Road, between Hartford and New Britain. The ten miles were run in 13½ minutes on the official test, and stretches of track were covered at a much faster rate than one mile a minute.

TELEPHONY AND TELEGRAPHY

THE SYNCHRONOGRAPH.—A NEW METHOD OF RAPIDLY TRANSMITTING INTELLIGENCE BY THE ALTERNATING CURRENT.—II.

BY A. C. CREHORE AND G. O. SQUIER.

IT is arranged that the brushes pass off from, and on to the paper, thus making and breaking the circuit, at the instant corresponding to the points in the current wave, Fig. 1, when the alternating current is naturally zero. The tape T passes over a wheel P geared to the generator shaft, so that for one revolution of the armature, the type advances a fixed distance. If the generator has ten poles, this fixed distance on the tape corresponds to five complete waves or ten alternations or semi-cycles of the generator current. One-tenth of this fixed distance corresponds to one alternation or semi-cycle of the current, and may be taken as the unit of distance in perforating the tape. If therefore a hole is made in the tape equal in length to this unit, and the brushes B and B′ happen to pass off from the paper so as to meet through the hole at the instant the current is naturally zero, then they will pass on to the paper again, breaking the circuit at the next following instant when the current is also naturally zero, since the length of the hole corresponds to one semi-cycle of the current.

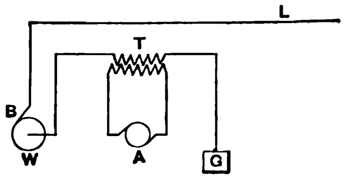

FIG. 8.

Suppose that a succession of these unit holes is made, the tape between the holes being also of unit length, then the circuit will be made and broken as by the first hole at the points of zero current. In practice it would probably not happen that the brushes were at first so situated as to pass off from and on to the paper at the instant the current is zero. In this case a succession of sparks appears, one each time the brushes pass on to the tape, and by moving the brushes along the tape it will be observed that this spark either increases or decreases in intensity, according to the direction moved; but at regular intervals, equal to the unit mentioned above, it disappears. This position of the brushes for no sparking is easily found by trial, and once obtained remains fixed. By this simple practical operation which experience shows requires but a moment to accomplish, the essential condition of synchronously operating upon the current in the manner described is secured. The brushes once adjusted always so remain, and since there is no sparking, it is possible to use high electromotive forces upon the line without injurious effect upon the brushes and tape. It is also plain that this method of operating upon the current is not affected by the speed of the generator, since the transmitting device is always in synchronism with the generator, whatever the speed. The speed of the generator, and consequently the rate of sending, as far as the transmitter is concerned, can be varied at pleasure between wide limits, without any effect upon the synchronous operation described.

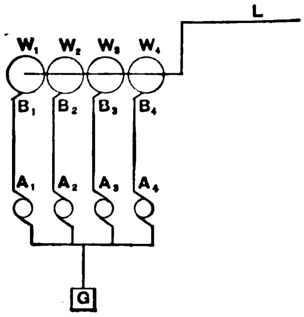

FIG. 9.

An example, giving the data from an early experiment, will illustrate how this is accomplished. The generator was a Fort Wayne 10-pole alternator giving a potential at its terminals of 1,000 volts. This was transformed to about 300 volts, being convenient to handle, and sufficiently high for the purpose. The end of the shaft E, Fig. 6, of the generator carries a small pinion, which engages the gearing G, and revolves the wheel P once in every 18.4 revolutions of the armature. This makes the 1-184 part of the circumference of the wheel P correspond to one semi-cycle of the current. The circumference of the wheel was about 100 cms., and the length of a unit, therefore, 1-184 of this, or .54 cms.

For convenience, a tape made of ordinary paper, had its two ends joined so as to make a continuous belt, which made it possible to use it repeatedly. The tape passed from the large wheel P to the loose pulley Q mounted upon a base-board A, and under the guiding pulley attached to the support S which controlled the tape, immediately before passing the brushes B B′.

In preparing the tape, the Continental code was employed as described, the omission of two half-waves meaning a dash, and one half-wave a dot. Having obtained the length of a unit on the wheel, the tape is first divided into these equal units, and then the proper units are cut out to form a message. The units which are not cut out form the dots and dashes. To use a continuous tape it is necessary for its length to be some exact multiple of the unit, in order that it may start on the second revolution exactly as it did the first. The generator current of high potential passed directly through the primary of a transformer, and the secondary was used as the source of electromotive force for the line. This secondary circuit which includes the line was brought to the transmitter to be operated upon as described. A diagram of the electric circuits as employed in this experiment is shown in Fig. 8, where A represents the alternator, T the transformer, B the brush bearing upon the transmitting wheel W, and L the line. Another diagram illustrating how the method may be used with currents of the same or different frequencies, is given in Fig. 9, where several generators A_1, A_2, A_3, etc., are represented upon the same shaft, and each is connected to a separate brush B_1, B_2, B_3, etc., bearing upon the wheels W_1, W_2, W_3, etc., upon a common shaft and connected to the line. By placing the insulating papers in the proper positions upon the wheels, it becomes possible to transmit in succession, first a current of one frequency and then of another, or of all at the same time.

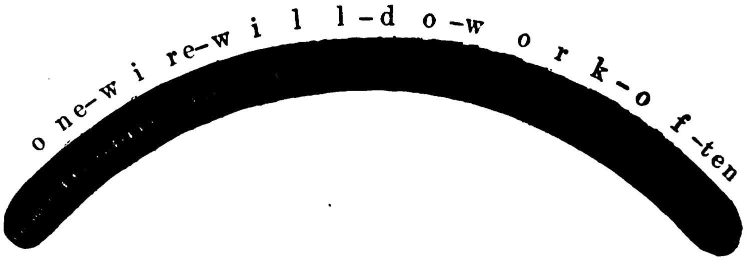

FIG. 10.

If any error is made in laying off the units upon the tape, or if the length of the tape changes in any way after they are accurately laid off, the effect of this error is cumulative from period to period, and although at any particular time the tape might be in phase, sometime later it would not be so, and sparking would occur. This would also be the case if there were any slipping of the tape around the wheel P. To overcome these difficulties it is only necessary to have holes punched at regular intervals in the tape which engage in pins at corresponding intervals on a wheel made to receive it.

A record obtained by the use of tape is shown in Fig. 10, where the sentence "one wire will do work of ten" was transmitted on August 10, 1896. This message was sent at the rate of 337 semi-cycles of current per second, thus requiring about half a second altogether.

Since the speed of transmission depends upon the frequency of the alternating current, the limit of speed is determined by the particular alternator used. In the above example the alternator available was designed to run at a speed of about 1,600 revolutions of the armature per minute, corresponding to a frequency of 133, or 266 alternations per second. To increase the speed of transmission this alternator was run as high as 2,400 revolutions per minute, beyond which it was thought dangerous to go. This corresponds to a frequency of about 200 complete cycles or 400 alternations per second. Through the kindness of Dr. M. I. Pupin of Columbia College, a special high-frequency alternator was loaned for the purpose of testing this system at high speeds of transmission. This alternator is in fact four alternators upon the same shaft, having 18, 22, 26 and 30 poles respectively. To obtain the highest speed, the

30-pole machine was used, and the transmitting wheel geared to the shaft as with the ten pole alternator. The speed of armature used was 2,180 revolutions per minute, corresponding to 1,090 semi-cycles per second, or 65,400 per minute, or a frequency of 545. No difficulty was experienced in sending and recording messages at this rapid rate which corresponds to between three and four thousand words per minute.

The Chemical Receiver.—In a practical form of receiver, it is an advantage to have the messages received in such form that they are ready for immediate use, and this is the case with the chemical receiver to which reference has already been made.

Through the kindness of Mr. Delany, some of the sensitive paper tape used in his system of machine telegraphy was obtained for experiments with the synchronous transmitter. A simple method of obtaining records of currents with this tape, which is certain in its action and does not involve any special apparatus, is to place the tape upon a smooth metal surface, which serves as one electrode, and to draw a steel needle, serving as the other electrode, along it guided by the straight edge of a ruler. If a direct current is used, no record appears when the current is in one direction, and it does appear when the current is reversed. If a second needle is substituted for the plate electrode, the record appears on one side of the tape for a direct current and on the other side for the reversed current.

If the two needle electrodes are placed side by side upon the tape, a record will appear at one needle for a direct current, and at the other for the reversed current.

By receiving with two needles side by side, all the alternations are recorded, those that were suppressed before now appearing at the second needle. The record then appears as two parallel lines of marks having the maximum intensities in one line opposite the spaces in the other.

The same message was then received in two lines, and one line gave the complete message as before, while in the other line there appeared a record for each complete unit in which the current was made. The papers of either the first or the second half of each complete cycle composing the message upon the wheel were next removed, and the message received in two lines as before. The result showed the message complete in one line, while in the other line appeared an uninterrupted succession of marks just as given by the simple alternating current received in one line.

If then an uninterrupted line of marks can be received in one line at the same time that a message is being received in the other, this uninterrupted line can be used for a second message entirely independent of the first. The next experiment accomplished this, and it is now possible to use the same line to send two entirely independent messages in the same direction at the same time at a high rate of speed. The preparation of the transmitting tape to accomplish this, simply requires that the two messages, each prepared with a double unit, shall be displaced a semi-cycle with respect to each other as they pass through the transmitter.

It is desirable in many cases to manifold the original copies of the message received, and experiments were made to accomplish this. All that is necessary is to attach to one terminal, instead of a single needle, as many needles as the number of copies desired, having each make its record upon a sensitive surface.

The alternating current is adapted to use with condensers in series with the line where a direct current cannot ordinarily be employed. An experiment was carried out to send a message through a condenser having a capacity of 9.57 microfarads in series with the line, and it was found that the message was transmitted correctly. One object of this experiment was to establish the possibility of using a set of Morse instruments upon the line at the same time that the messages were being transmitted at a high rate of speed by the alternating current. By shunting condensers around the set of Morse instruments it was found that the opreation of either system did not affect the working of the other, so that it becomes possible to use the same high speed line for a complete system of quadruplex telegraphy at the same time. Indeed it seems possible that the present Wheatstone system could be operated over the line in conjunction with the alternating current messages.

The use of the alternating current as a means of sending intelligence in connection with the fact that a message can be sent through condensers, suggests the possibility of using the principles of electric resonance employing circuits having natural periods of their own which will pick out and respond to currents from the line having their own frequency.

A characteristic of the records made by electrolysis is the natural separation of the positive and negative waves of current, which is an advantage in interpretation. This separation is also accomplished in the polarizing receiver by employing two receiver tubes.

A TELEGRAM FOR A PARADER.

"The telegraph messenger," said an old-time messenger boy, "has to deliver messages in many strange places. I saw on the day of the Grant celebration, the delivery of a dispatch to a man in the procession. It might seem as though it would be difficult to find a man in a procession, he being, in such a procession as this, one man among fifty thousand, and it might be difficult under some circumstances, but ordinarily it would not be, for the messenger would in all probability start with a knowledge of the regiment and company to which the man to whom the despatch was addressed belonged, if he did belong to such an organization, and then all that would be necessary would be to locate the organization, a task comparatively easy with the aid of a programme and a little figuring as to how far the regiment would march in a given time.

"This message that I speak of was for a member of the staff of the Governor of Ohio, then riding up Riverside Drive. Its prompt delivery was as simple a matter as rolling off a log. The Governor and his staff were singled out without the slightest trouble by means of their State flag. Without the slightest hesitation the boy tackled the Governor and handed him the dispatch. The Governor saw at a glance that it was not for him and motioned the boy toward his staff. The boy tackled then the first man he met, and that member of the staff indicated to him the member to whom the despatch was addressed. The messenger promptly delivered it. To find the right man he had found it necessary to go to but three men out of fifty thousand."

ELECTRIC TRANSPORTATION

AMERICAN STREET RAILWAY FINANCE.—V.

BY E. E. HIGGINS.

(Concluded.)

THE return circuit has always been a source of weakness in electric railroads. Originally, galvanized iron bonds were put in, but practice soon changed to copper bonds. There has been always more or less corrosive or electrolytic action between the iron of the rail and the bonds, and the bonds have given considerable trouble in their way. They have been recently improved very materially, and now are perhaps of nearly equal efficiency to overhead appliances, but are by no means perfect and are always likely to give trouble. It is probable that the return circuit in most cases cannot be made by bonds alone, but some form of supplementary return wire will be necessary. The original method was to put supplementary wires in the center of the track, and connect them with the different rails, but the practice now is to establish certain centers of current collection as it were, from which centers the current is drawn off to the stations through return feeders carried on poles, or in some cases, underground, where the earth is of a suitable nature.

I think in large systems these return feeders are necessary and should be adopted, and there should be great care taken in making frequent tests to determine the difference of electromotive force between the rail and water and gas pipes which are underneath the rail. The electrolytic action on the gas and water pipes is a serious matter, but it can be cured. The cure lies broadly speaking in the destruction of any difference of potential between the rails and the pipes. The instant you have a difference of potential, you have a flow of current and that flow of current will destroy the pipes. The methods of preventing differences of potential from arising are pretty well known, and consist in localizing it in certain places. The area near the power stations is the most dangerous, and that remote from the power station gives very little trouble. If you provide as nearly perfect bond connection of your rails as can be had, and bind the rails and the water pipes together, where the difference of potential is great or the earth resistance small, there will generally be little trouble from electrolysis.

Underground conduit roads are often urged as a cure for the evils of the overhead system. They certainly are a cure in many respects. None of us like the overhead wires, and we would all be glad to get rid of them. The difficulties in the way are obvious, chiefly in the matter of the initial cost, and consequently of the return on the investment. The open conduit now being put in in this city is probably as inexpensive as any open conduit can be. It is made quite shallow, much more so than cable conduits; it is built from the top down and not from the bottom up, so that it is not necessary to provide the foundations which are found in the old construction, and the conduit is apparently worked with entire success and economy, the initial cost being the principal item against it.

There has been a good deal of talk about closed conduits, and it is certainly true that closed conduits are theoretically very pretty devices, and if we could put aside certain practical disadvantages, we would have something quite interesting. The main disadavantage lies in the installation of 500 to 1,000 pieces of mechanism per mile of track. You have the magnets, armatures and contact points, and to have 1,000 of them for every mile of double track, or even a less number, is to make it almost certain that sooner or later, and probably very frequently, some one, or a number of them, are going to get out of order and give trouble and block the line. There is one thing that the street railway manager is certain about—his line must not be blocked under any circumstances.

Another serious disadvantage of the closed conduit lies in the liability to sweating inside the tube due to condensation of moisture in the atmosphere. It is impossible to keep air out and impossible to make perfect joints where the contacts come, and I am pretty sure that, as a matter of fact, closed conduits would give serious trouble from this and other sources.

The matter of road bed is one of which I shall say very little. The standard construction to-day is with deep girder rails, nine inches where paving blocks are used, and seven and eight inches where other forms of pavement are used, or where paving blocks are of smaller size. With joints of sufficient strength, we hope this construction is going to be good. As a matter of fact, however, I think that the difficulty with these deep girder rails is going to be found at the joints, and less in the pounding of the joints themselves than in flattening out and forming hollows, due to the rails having insufficient carbon. I am not an expert on the subject of rail manufacture, but this thing is certainly true, that steam railroads are specifying higher percentages of carbon than they have ever done before, and are consequently getting rails which are harder and ought to withstand wear better. It is true that we can go still higher in carbon in street railroad rails than the steam railroads can, as far as the liability to accident is concerned, which is one of the limiting features in steam railroading. Steam railroads cannot afford to have a rail break; it means usually an expensive accident, and a tremendously expensive accident if it is a passenger train. Electric railroads have no such limitations. There is no serious liability to an accident on account of a broken rail. The rails are imbedded in the pavement and cannot move upward or sidewise to any material extent.

I believe firmly that street railroad managers ought to investigate very carefully the results obtained with rails of different percentages of carbon and other elements and take into account in general all the features of rail composition so as to get a strong, tough, hard rail, and something that will not "squash" from softness, as many of the rails are doing.

There are any number of different kinds of joints. The ordinary channel plate joint has been found to be too weak if less than thirty inches in length, and thirty-six inches, and even greater lengths are put in by conservative roads. Cast welding and electric welding are in use to some extent. Cast welding is the living hope of a great many roads, not only in new construction, but in bringing up the joints of old construction. We do not know enough about it yet to predict surely what the results will be. There are many patent joints, some of which are good, and some are worthless.

The special work is always an important feature of track construction, an extremely expensive feature, and one which ought to be considered with great care to have the rails and grooves fit the wheels. That is to say, the wheels and the track in general, and the special work in particular, ought to be determined upon in view of their mutual relations. It is something which is not done to any adequate extent, and street railway companies are discovering this to their cost, and will continue to do so if they do not make a radical change. Where wheels grind out special work, or special work breaks wheels, something is wrong.

The rolling stock of America is, I suppose, better than that of any country in the world, and is really well constructed. The cars are lighter, more elegant and their lines are laid out with the idea of getting great strength with the least weight. As far as the seating arrangements are concerned, it is difficult to see any improvement from the point of view of the public. Some of the long double truck cars are as comfortable and easy to ride in as can be desired.

The trucks are an interesting portion of the rolling stock, and there is, of course, a large variety of them. The style of the old horse railway truck, which was followed for a short time with electricity, was to fasten the car bodies directly to the axle boxes. The independent motor truck was then developed and is in exclusive use to-day. With single truck cars, one of the grave difficulties is the oscillation of the car body, particularly when speeds are considerable, and this oscillation is prevented in many cases by the extension of the spring base to a considerable portion of the entire car length. Sometimes, however, unless the spring is carefully graduated, there are difficulties introduced in a peculiar jarring motion of the car, which is disagreeable to the passengers, and great care must be taken in the manufacture of trucks to avoid this.

Hand brakes, air brakes, electric brakes, mechanical brakes, all have their place and all are being experimented with, with a good deal of care to determine some means of keeping down the accident account. It is hard to tell where the best results will come. There is much to be said in favor of each, and all must hope that the very distressing accidents which occur at times will in some way be prevented, both because of the street railway companies' exchequers and on the score of general humanity.

I must omit discussion of the electric equipment apparatus, as it is far too broad a one to undertake at this late hour.

REQUIREMENTS OF HIGH SPEED AND HEAVY ELECTRIC TRACTION.—II.

BY HAYWARD COCHRANE AND E. J. SWARTOUT.

In Fig. 4 is shown a Pullman motor car, representing a leading type of such apparatus for high speed work. The windows are so designed as to make the car convertible to meet the requirements of the seasons.

The arrangement of partitions should be about as shown on the plan Fig. 5 for suburban and small cross-country roads where the motor car is used for baggage, express, mail and smoker. For a road operated by direct current, it would be a nice arrangement to have the lights, and possibly the heaters, in each car fed from independent groups of storage cells. In case the train became stalled from failure of power circuit, the lights at least could be kept on for a considerable length of time, probably until the power circuit was put into working condition again. By charging batteries in series and connecting lights to groups at lower voltage there would be greater safety in controlling them and they would be less subject to flickering than in the case of present manner of connecting. By having skilled motormen, a saving in energy used to accelerate trains could be effected and the item of depreciation of rolling stock reduced to a minimum.

The speeds attained by elevated and ordinary suburban trains is about 30 to 35 miles per hour maximum, which is doubtless high enough for frequent stopping. For express suburban service, however, considerably higher speeds, say, of 40 to 45 miles per hour, might be advisable. For suburban service it would seem best to use elevated or partially elevated track in city limits, with no grade crossings, and a third rail trolley, but for the suburbs to have the overhead trolley, since it would be impracticable to use the third rail where there were street crossings at grade.

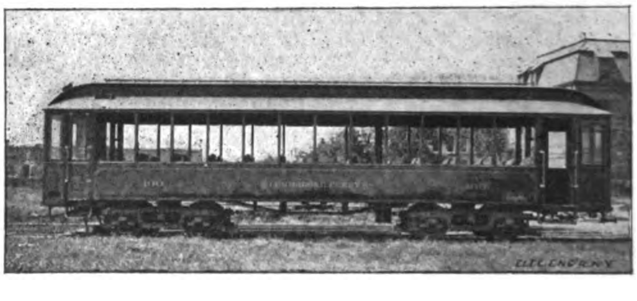

Fig 4.

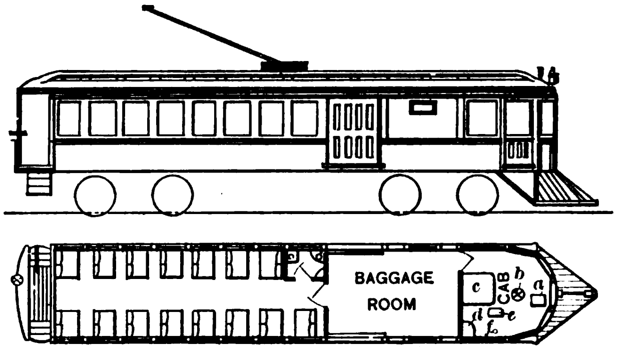
We are informed by the Walker Manufacturing Company that one of their 32-ton motor cars equipped with four 50 horse-power motors hauled six open coaches, each of 10 tons, at a speed of about 30 miles per hour, the total load upon the motor car and coaches being 670 persons. An ordinary trolley with No. 00 trolley wire was used and gave very satisfactory working. The total weight of empty motor car and coaches was 184,000 pounds, and assuming 150 pounds per passenger the total load was 105,000 pounds, or a load per car of 15,000 pounds. The total train weight would, therefore, be 284,000 pounds on 142½ tons. Assuming a tractive power of 27 pounds per horse-power of motors or 5,400 pounds for the four motors, the tractive power per ton of train was 37.8 pounds, or a little in excess of that for the largest Rock Island train, while the adhesive power was 14,400 pounds, or 166 per cent. of the tractive, or a trifle in excess of that for the Rock Island locomotive or the elevated railway motor cars.

For heavy suburban services, assume a train of five closed coaches hauled by a motor car equipped with 250 horse-power nominal capacity, either four motors of 62½ horse-power, one to each axle, or two motors of 125 horse-power linked to pairs of axles, so as to obtain the full adhesive weight of the motor car, all its weight then being upon the drivers and, therefore, effective weight. If closed coaches of 32,000 pounds were used, five loaded coaches would weigh 210,000 pounds or 105 tons, but the six loaded coaches of the Walker train weighed 103 tons, assuming 1-7 of the total number of passengers to be in each coach. We may therefore assume for a heavy closed car train of five coaches a motor car of about 35 tons, or 70,000 pounds, this, plus a load of 10,000 pounds, or five tons makes a total train weight of 145 tons. Assuming an approximate tractive power of 27 pounds per horse-power, gives 6,750 pounds as the tractive power of the suburban motor car. Assuming an average weight of motor car of 37 tons, we have an adhesive power of 16,650 pounds, or 146 per cent. of the tractive power.



Elect. Eng'r., N.Y.

FIG. 5.

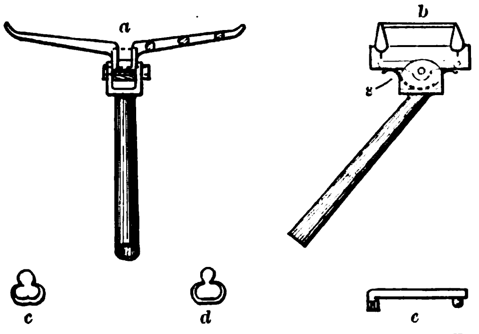
With a direct current power system working at 500 or 600 volts pressure, say, 600 volts (which would probably be best for any ordinary length of suburban road of about 15 miles, not over 20,) a current of about 440 amperes would be required for the full rated capacity of the motors. On starting the train, a much larger current would be called for under ordinary conditions, a current which would be excessive for passing through such contact surface as would naturally obtain with the trolley wheel. To obviate this difficulty, we suggest the use of a trolley shoe substantially as shown in Fig. 6 (a and b); the shoe is shown separate at e. If this shoe were of metal, the trolley wire shown at c and d might have a soft steel shield rolled upon it to take the wear; or if the shoe were made of a mixture of plumbago and carbon, the plumbago would act as a lubricant and the ordinary hard drawn copper trolley wire could be used. The holder of the shoe can be made very light and provided with arms, as shown at a, which are intended to extend only high enough at the sides to catch the trolley wire whenever by accident the shoe might leave it. The upward pressure of the shoe need be no greater than that now employed in the case of the trolley wheel. The shoe is designed to be about 7 inches long and wide enough to follow any ordinary curvature in the trolley wire. The shoe holder is pivoted at right angles to the trolley wire and rests against a half-elliptical spring, s, which allows the shoe to fit to the wire while the angle which the trolley pole makes with the wire may vary considerably. The contact surface between the wire and the shoe is so much greater than with the trolley wheel that a much greater current can pass with no increase in sparking.

For short cross-country railroads of 30 to 60 miles length with light traffic and for long trunk line roads, it would seem almost out of the question to use the direct current system. The ideal for such lines would be the alternating current complete from generating station to car axle. At the present time, however, there seems to be no practical method of operating such a system. In order, therefore, to operate successfully such roads, taking into consideration the cost of installation and interest thereon, one of two lines of engineering should probably be proceeded upon. In either one the use of the alternating current at a pressure of 10,000 to 20,000 volts with step-up and step-down transformers for transmission from a central generating station to substations at intervals along the line, for roads 30 to 100 miles long would be used. One plan would be to place at each substation static and rotary transformers which would furnish direct current to The controller lever (Fig. 3), is shown as having a catch or dog which engages with notches in a quadrant. Looking from the pivot of the lever as shown, the narrow notches at the left are for varying the field strength of the rotary transformer when the motors are in plain series connection. The first wide notches are for making the changes in the commutations of the motor field windings, the motors still being in series. The set of narrow notches is for varying the field strength of the rotary transformer when the motors are connected in plain multiple. The second set of wide notches at the right are for making the changes in the commutations of the motor field windings, the motors being connected in multiple. In stopping the train, the controller could be arranged so as to break the current over a large number of points simultaneously and instantaneously.

By placing both static and rotary transformers in the substations, the cost of copper for sub-feeders at 500 volts for a road of any considerable length would be enormous; besides, there would be extra cost for attendance at substations, and in considering such an outlay, the probable business to be done by the road would have to be carefully estimated. For heavy trains and very high speeds, moreover, Mr. Wm. Baxter, Jr., estimates that electric locomotives should have a maximum horse-power of at least 1,250. This, on a 500-volt circuit, would call for more than 2,000 amperes and would necessitate an extremely heavy overhead construction if a trolley were used. If the third rail system were used there should be no street crossings at grade, and in countries where snow falls there would be an endless amount of trouble at times with the third rail on account of drifting. By placing the rotary transformers on the locomotives and having a pressure on the trolley wires of 1,000 to 2,000 volts, it would be necessary to insulate specially the conductors leading from the trolleys to rotary transformer from the frame of the locomotive, which fact would almost prohibit the use of the rails as one side of the circuit.

The tri-phase alternating system seems to be better suited to this class of work than the single or two-phase system. because it would save about 25 per cent. of the copper necessary for the former system. The trolley wires and feeders could be of comparatively small cross section, so that the overhead construction need not be extremely heavy, though it would of necessity be quite complicated. While the double and triple trolley system would have many objectionable features, yet they seem to offer at the present time about the best solution for the conducting system of long distance electric traction. In planning the static transformer substations it would be well to install at alternate stations a duplicate or relay transformer bank so that in case any working transformer bank became disabled it could be cut out and the sections of the road not over 15 miles long at a pressure of 500 to 700 volts and use a single trolley and rail-return circuit.

The other plan would be to have the substations further apart than in the former case and to install in each one a bank of static transformers which would deliver an alternating current of 1,000 to 2,000 volts to double or triple trolley wires of small cross section; then to have upon each motor car or locomotive a rotary transformer of a capacity ample for any demand made upon the motors, which would receive direct current from it at 500 volts pressure. The efficiency of fully loaded static or rotary transformers is high, and is very good at medium loads.



Elect. Eng'r., N.Y.

FIG. 6.

By using this system also, a special method of control might be employed. In connection with series motors, use the series-parallel commutated field method as previously herein suggested, and if greater ranges of speed were desired it might be practicable to vary the field strength of the generating side of the rotary transformer by means of a rheostat.

relay cut in temporarily. The pole line should consist of iron pole construction, and the erecting and spacing of distances should follow the plan of the best street railway installation, except that specially designed double insulating trolley wire hangers and feeder wire supports should be used. The locomotive should be provided with an electric brake as well as an air brake for very high speed service as an extra factor of safety; a brake similar to that of the Sperry design might be employed.

The arrangement of the locomotive cab for a combination baggage and smoking car is shown in plan view in Fig. 5. The rotary transformer, c, is shown slightly to the left of the center line of car and at the rear of the cab opposite the motorman's seat. The latter, d, is close by a sliding window similar to that of a steam locomotive. The controller, f, is at his left and slightly to the front and close to the rotary transformer. The air brake valve, f, is in front of the motorman and close to the side of car. The hand brake, b. is close to the controller at the front of car. The air pump, a, is in front and slightly to the right of center line of car so as to counterbalance, with the weight of controller and rheostat frames, which are not shown, the position of the rotary transformer.

For heavy trunk line work an independent locomtive should be used in which case the rotary transformer should be placed at the middle, and the air pump and rheostat frames disposed so as to counterbalance the weight of the controller which could be at one side. By not using the rails for one side of the power system, an electric block signal system could be employed which could automatically stop a train in block No. 1 if block No. 2 were not clear.

Each train should be provided with a hand telephone, and the line supplied with a metallic circuit with branch blocks about eight to the mile so that disabled trains could easily get assistance from the nearest station, using the batteries at that station for telephoning. Terminal facilities in large cities could be supplied by 500 volts direct current on the single trolley or third rail system, and if tracks were partially or wholly elevated, as they should be, this plan would work very nicely.

THE BEAUTIES OF THE ECKINGTON AIR MOTOR CAR.

By T. P. KANE (Washington, D. C.)

WHILE the experiments made in Washington during the past several weeks have tended only to strengthen my belief that compressed air cannot successfully compete, mechanically or commercially, with electricity as a motive power for surface street railways, Congress having declared that the former shall be given a fair trial on the Eckington line, the system should be earnestly, fully, and fairly tested, instead of the time limited by law for its trial being frittered away by such unsatisfactory and indefinite performances as have been witnessed since the experiment began.

Being curious to know whether, in my estimate of the car on trial, I was blinded by the prejudice which I am charged in some quarters with having against compressed air in any form, I interviewed a number of persons who have ridden upon it, with a view to learn their opinions in regard to it, with the following result:

Mr. S. M. Gaines, of Brookland, said:

"My experience in riding on this air car makes it plain to me that it is not a success, mainly for the reason that it has not sufficient power to ascend even a moderate grade. It seems to me also that the heat produced by the smokestack which runs through the car would be intolerable in summer, and the dust drawn into the car by suction must necessarily be very disagreeable to passengers. Taken altogether, the car seems to me to be a very crude experiment."

Mr. L. O. Murray, a student at the Catholic University, said: "I have ridden on the car several times, but have had quite enough of it. I always wait now for the horse car, preferring to sacrifice a few minutes of times in traveling by slow horse than to reach the city in a cloud of dust, and in odors that remind one of an engine room when the cleaning process is in full blast. The smoke and odor from the fire which the car carries, together with the dust which it sucks up through the grating in the floor over the fire, makes riding on it so disagreeable that I have abandoned its use entirely. I do not see how a car with all the disagreeable conditions displayed here can ever be satisfactory to the public."

Mr. R. R. West of Brookland said: "I have been on the car a number of times. My judgment of it is that it cannot be considered a success, except so far as it seems to be able to make a good speed on the level. The heat, for one thing, from the smokestack is very disagreeable on a warm day. I had occasion to sit beside this pipe one morning when the car was crowded, and found it decidedly uncomfortable. I should think this feature of it would make it a very unpleasant car to ride in in summer. Another disagreeable feature of it is the odor which arises from the fire underneath the floor and the cloud of dust which it seems to draw up through this opening when the car is in rapid motion. I am not favorably impressed with the car."

Mr. W. P. Armstrong, of Brookland, said: "I have not been a frequent rider on the car, and do not consider myself competent to pass judgment upon its merits. I have noticed, however, that there is considerable heat thrown off from the smokestack in the car, and not a very pleasant odor escapes from whatever sort of fuel is used for the fire which the car carries. Smoke and dust seem also to fill the car through this opening in the floor. Taken altogether, I do not think it will prove satisfactory; but, if adopted, might be an improvement on horse service, in so far as speed is concerned, until we can get something better."

Mr. Bernard Waters, of Quincy street, said: "I have not ridden on the car much, because I have not been able to find it. When I have been on it it has had to stop at Quincy street to let me off, and has hardly been able to surmount the insignificant grade at that point leading up to R street. I have watched it go up the hill, and it was as much as it could do to get up, and then only by puffing and snorting like an old freight engine. It is like everything else connected with the Eckington road—no good, and, like that old dromedary they run over a year on North Capitol street, they will use it as long as they can get it for nothing. Instead of giving us a good service, like is used in other sections of the city, I suppose they will try to foist this infernal machine upon us for the next few years as a time-killer. I do not regard the car as a success, and Mr. Schoepf knows it is not."

Mr. T. T. Moore, of 55 R street, said: "I have ridden on the air car whenever I have been able to find it, and I think it is the crudest form of rapid transit I have ever been on. Between the cloud of dust that it seems to move in, the smoke from the fire under the car, the heat from the smokestack in the car, and the odor from the coke that they burn all combine to make it anything but a satisfactory form of rapid transit such as is required by the act of June 10, 1896."

The foregoing are a few samples of a stock of similar opinions which I have collected, but the length of this communication prevents their publication.

My own experience in this car confirms everything these gentlemen say of it. I have seen men on it roll their coat collars up and button it across their bosom to keep out the dust. I have seen ladies use their handkerchiefs to keep the dust and odor out of their noses. I saw two ladies signal the conductor to stop the car, and one of them in passing me said: "Let me off this car or I'll choke to death," and she got off it coughing the dust out of her throat. Another one said: "I can taste the odor from that fire," and no end of complaints and comments can be heard about the heat from the smokestack.

Its operators say the dust is due to the cobblestone pavement on New York avenue, and that any other rapidly moving car would raise the same cloud, but it matters not whether it be on asphalted G street or cobblestoned New York avenue, the experience is just the same.

Receiver Schoepf claims to have been experimenting with cold air when the car got stranded on the Eckington grade, yet he knows full well that at that time the car had on it the same old fire pot and hot smokestack, and that it was impossible for him therefore to pass the air through the coil of pipe to the cylinder without its being heated. He also knows that experiments with cold air have been tried and failed years ago, and that if he had been making an experiment as alleged he would have done it under cover of darkness, as he tried the grade of Louisiana avenue, and has not dared to repeat it in daylight unedr the public gaze. Mr. Schoepf cannot blow hot and cold upon public credulity in that sort of fashion.

BIG TROLLEY DEAL IN ST LOUIS, MO.

The largest street railway deal in the history of St. Louis was completed recently when a controlling interest in the Missouri Railway Company was transferred to parties who represent the Lindell Railway Company. Nearly $2,000,000 is represented in this transfer. The Missouri Railway Company operates three lines—the Olive street cable, the Market street and Manchester electric road and the Laclede avenue electric. Its authorized capital is $2,500,000, of which about $2,200,000 has been issued. The par value of the stock is $100 a share, but it has been selling at $150 recently. The price at which this transfer was made is said to be $165. The bonded indebtedness of the Missouri Railway Company is about three-quarters of a million, and the bonds are above par at present.

ELECTRIC LIGHTING

STEAM HEATING FROM ELECTRIC CENTRAL STATIONS.

BY I. H. BABCOCK.

WE frequently get inquiries from electric station managers in relation to the distribution of their exhaust steam for heating by the Holly system, buit by the American District Steam Company, of Lockport, N. Y. This has been a subject of growing importance since the advent of electricity as a motive power. Every city or village of any importance has its electric lighting plant, or a railway system in which electricity is the motive force. In some instances they are combined. Except in a few cases where water power is available, a steam station is at the foundation of the enterprise. These expensive boiler plants have multiplied rapidly with the growth of the electrical business.

In engine work between eight and nine-tenths of the steam which is generated escapes through the exhaust pipe after doing its work in the engine. This has caused the question to be raised as to whether this waste product might not be used for heating, thereby increasing the profits of the company operating. In gas manufacture, and in oil and sugar refining, the by-products are a vital part of the business, and no concern could successfully compete that allowed these to go to waste. Enough has been demonstrated already to show that the matter of heating by the exhaust from stations is of so great importance that it should be investigated by all companies whose stations are suitably located contiguous to heating territory.

The Springfield, Ill., Electric Light, Heat and Power Company has been operating such a plant for the last six years, and, we are assured, with great success. They have several times made extensions of their heating mains, and claim that they have paid the expense of installing the steam system two or three times over out of the net profits from heating. This company is not more favorably situated than scores of others.

The additional cost of operating is very slight, as the station expenses for labor remain the same, and office expenses are not increased. The coal account is but slightly increased, except that at times some live steam may be required when some of the engines are idle.

Another company in the West is heating in the same way by exhaust from its railway and lighting power station. Ten million cubic feet of space is being heated. Here is what the manager says: "We are operating six high-speed cross compound engines, four 150 horse-power, and two 250 horse-power each; also three 75 horse-power Armington & Sims high speed engines, single expansion. We carry 2 pounds back pressure on our engines for heating in moderate weather, and about 5 pounds in zero weather. We do not notice any difference in the working of our engines on account of the back pressure. We have about 1,000 horse-power in boilers." It will be seen that both compound and simple expansion engines are being used without embarrassment. The testimony here and in other places is to the effect, that, if the boiler pressure is raised by the amount of pressure required in the heating mains, no difference can be seen in the working of the engines.

Where individual steam systems of heating are in use they can easily be connected with the heating mains, and we are informed that scarcely without an exception they at once adopt the district plan. As these small boiler plants are all run at low pressure, the low pressure from the exhaust mains performs the work to even better advantage, because there is a constant supply at all hours. This enterprise is comparatively new with the electrical companies, but it has been adopted already in a good many places, and we think the matter is worthy of the attention of station managers generally.

THE WALKER ARC LAMPS.

FOR some time past the Walker Company, at Cleveland, has been engaged in the development of a complete arc-lighting system, and the first of the details of this system to make its appearance are their new arc lamps, a view of which is given in Fig. 1, which represents the out-door type.

In compliance with the general demand for a short arc lamp, the new Walker lamp is only 34¼ inches long, while the length of a fresh trimming of carbons is 26, thus making the lamp only 8¼ inches, or 32 per cent. longer than the length of carbons employed.

The Walker arc lamp has been designed with the idea of obtaining the steadiness of the rack feed and simplicity of the clutch, the rod being done away with entirely. In its place there is substituted a wheel of small diameter with an accurately turned rim on the edge of which the clutch operates. The carbons are fed by a chain, as shown in Fig. 2, and this chain drives a sprocket wheel, mounted on the same spindle that carries the clutch wheel. Both carbons are fed, and the arc remains practically stationary. Another improvement is the connection of both carbons positively with their sources of supply by means of flexible cables.

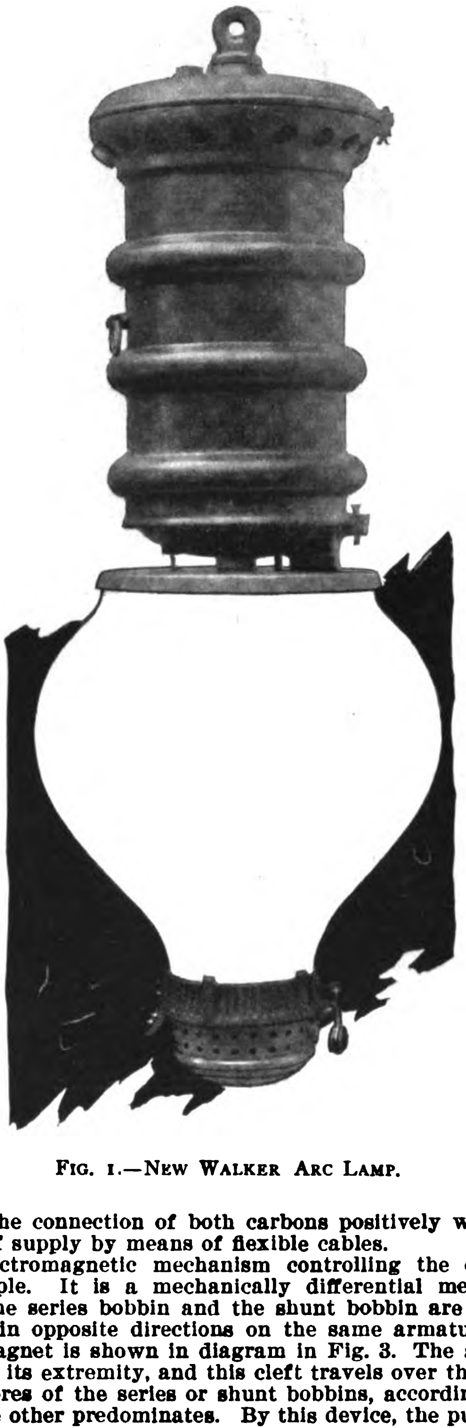


FIG. 1.—NEW WALKER ARC LAMP.

The electromagnetic mechanism controlling the clutch is very simple. It is a mechanically differential mechanism, that is, the series bobbin and the shunt bobbin are separate and pull in opposite directions on the same armature. The electro magnet is shown in diagram in Fig. 3. The armature is cleft at its extremity, and this cleft travels over the wedge-shaped cores of the series or shunt bobbins, according as the one or the other predominates. By this device, the pull on the armature is made uniform throughout its travel, and there is no need of weights or springs.

The electrical connections of the lamp will be understood from Fig. 3. When the lamp starts, there are across the terminals three paths, and two that are important. One is a resistance of about 1 ohm as shown. This resistance performs an important office that will be presently considered. The second path is through the carbons, which are together, via the series coil. The third is the shunt bobbin, but at the start the current in this part is too small to be considered. The resistance is of such proportion that enough current passes through the series coil to start the lamp the moment the armature moves, and when the carbons are drawn apart R is cut out by a special cut-out, which is diagrammatically shown in the figure. The voltage of the lamp rises to its normal value. The shunt coil takes hold and regulates and feeds the lamp in the ordinary way.

There are two distinct automatic cut-outs in the Walker lamp which act under different circumstances. They are both mechanical and one is operated by the same mechanism that operates the carbons and the other by the upper carriage which supports the upper carbon.

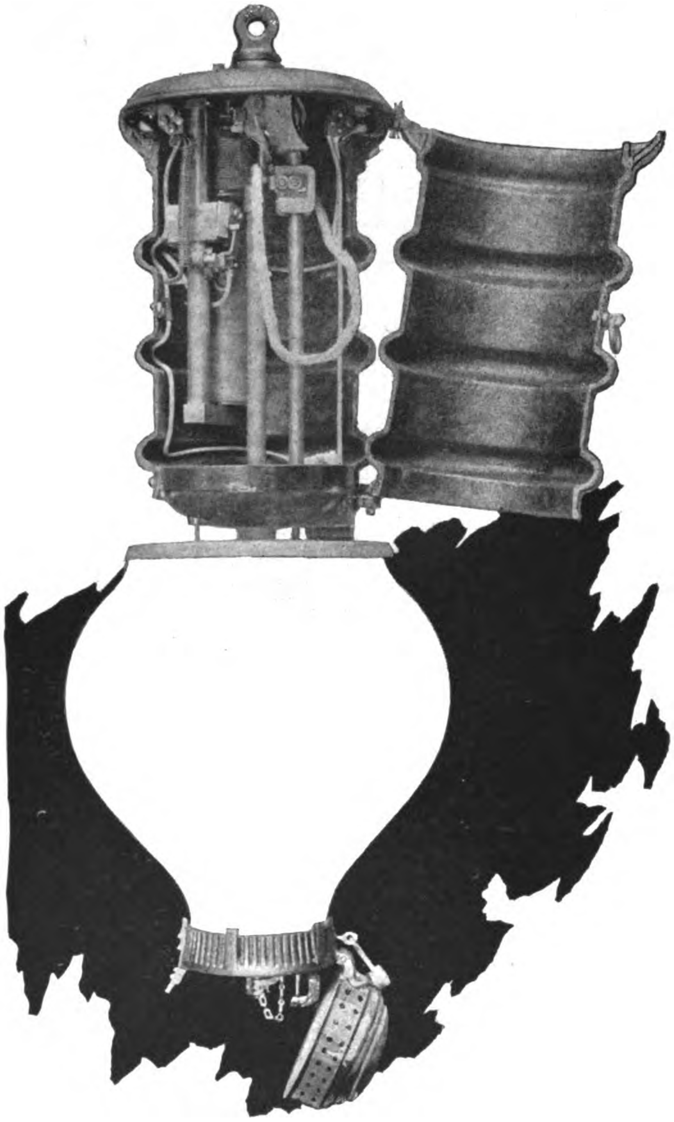

FIG. 2.—NEW WALKER ARC LAMP.

The latter, which is in the base of the lamp, dead short-circuits the lamp when the carbons are burned out, and as stated above, is actuated by the weight of the positive carbon carriage, which descends directly upon it. This cut-out is also moved by a lever from the outside when it is desirable to cut out the lamp for trimming or any other purpose.

The other cut-out has the same functions that the ordinary cut-out in a series arc lamp always has, namely, to provide a shunt circuit for the current in case the carbons stick and fail to feed, or in case either carbon should be broken, or through some accident become unduly separated. It also provides a path for the current when the carbons are consumed, if for any reason the cut-out in the base of the lamp fails to act.

The resistance which is inserted between the positive terminal and this cut-out is for the purpose of shunting sufficient current through the series coil and carbons to start the lamp, and is common to all differential series arc lamps. In the Walker lamp, this resistance is made of especially high resistance wire, having a resistance approximately three times that of German silver, and also having mechanical properties, which are such that it can be heated to redness without affecting it in any way.

The convenience of the Walker arc lamp is one of its main features. Both the carbons are clamped at one end with a universal joint, and are made to nose together by two centering rings, which are as near the arc as is practicable. The upper centering ring consists of a bushing in the base of the case. The upper carbon is contained in the case with the mechanism and feeds out through this bushing. The globe is readily lowered for trimming and is covered with a reflector plate, which performs the double service of arresting the sparks and reflecting the light downward. The carbon dust can be brushed in the dust cap below, which can then be removed and emptied. These features are well illustrated in Figs. 2 and 4. It is important to note also that no part of the lamp frame is alive. The arc is practically stationary, and the

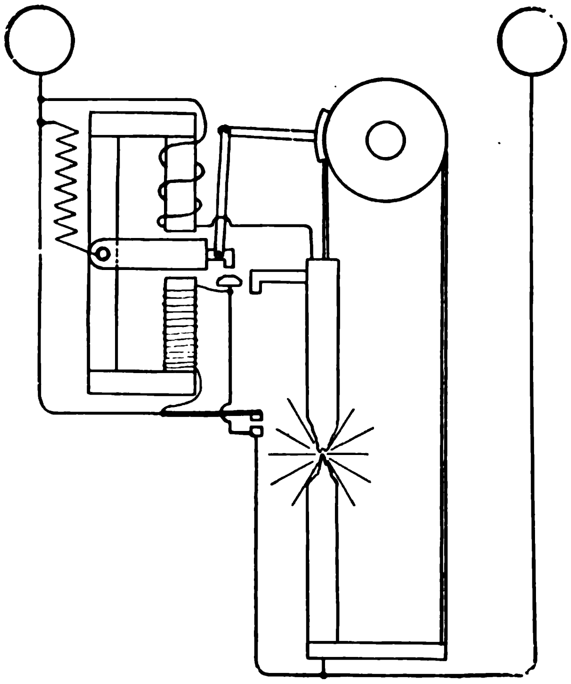

FIG. 3.—NEW WALKER ARC LAMP.

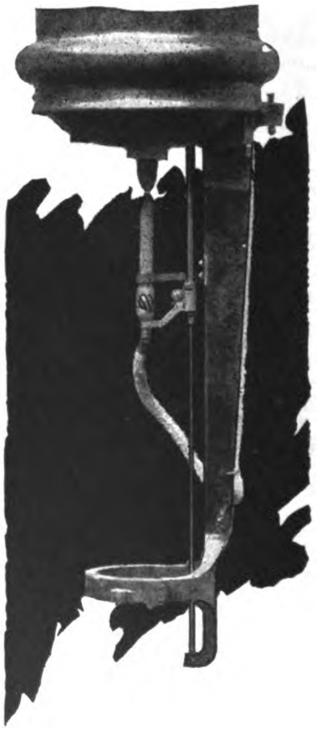

FIG. 4.—NEW WALKER ARC LAMP.

heat on the globe is therefore uniform and not liable to crack it, as is the case with the traveling arc.

The Walker Company also manufacture an enclosed arc lamp. We understand that their new arc machine will be ready for the market soon.

SOCIETY & CLUB NOTES

THE ELECTRICAL ENGINEERS' MEETING AT GREENACRE, ME.

With regard to the proposed meeting of the American Institute of Electrical Engineers at Greenacre, Me., the following details will be of interest:

In 1894, Miss Sarah J. Farmer, daughter of the late Moses G. Farmer, the well known pioneer in electrical discovery and invention, established at Greenacre, Eliot, Me., a unique and interesting movement for the education and elevation of the people. It was not a "Summer School" in the ordinary acceptation of the term; but a place where all the advantages of summer rest and recreation of a rational character could be combined with rare opportunities for the development of the higher nature.

The leading idea of the Greenacre lectures was peace and unity, to be sought through the presentation and comparison of the constructive places of progressive thought in every field of study and investigation. The platform was broadly ethical and purely humanitarian. Physical rest was sought through the quickening and energizing of those spiritual, mental and moral faculties which are too often neglected in the struggle for existence under the high-pressure methods demanded by our modern civilization.

The Greenacre movement was morally a success from the start. Lecturers of the highest ability contributed their services without money and without price. Weary workers with brain and pen found hope and inspiration in the words of life which came from the lips of speakers inspired by the highest ideals, and giving freely of their best thought under the rare influences contributed by the natural beauties of the place and the atmosphere of rest, peace and unconventional social life which prevails at Greenacre.

The little Inn has been taxed to the uttermost each season to accommodate those desiring to avail themselves of the privileges of the place, overflowing into a colony of tents and the neighboring farm houses, and this year necessitating an enlargement of accommodations to meet the increasing demands.

Such speakers as the venerable Prof. Joseph Le Conte, of the University of California, Prof. Amos E. Dolbear, of Tufts College, Prof. Edward S. Morse, of the Peabody Institute, Salem, Mass., Dr. Lester F. Ward, of the Smithsonian Institution, Washington, D. C., Dr. John Fiske, the eminent historian and philosopher, Judge William C. Robinson, Dean of the Catholic University, Washington, D. C., the Hon. Carroll D. Wright, U. S. Commissioner of Labor, the Hon. Neal Dow, the Rev. Dr. Edward Everett Hale, the Rev. William R. Alger, Mr. E. D. Mead, of the "New England Magazine," Mr. Frank B. Sanborn, of Concord, Mass., Dr. L. Dickerman, the Egyptologist, Mrs. Mary A. Livermore, Mr. F. Edwin Elwell, the sculptor, and many others of equal note, have contributed their services at Greenacre, while from distant India the Swâmi Vioekânanda, the Swâmi Sâradânanda and Mr. Jehangier D. Cola, of the Parsi Community in Bombay, have come to emphasize and illustrate the cosmopolitan and unsectarian spirit of the Greenacre assembly.

Last year, this feature of the work took definite shape in the organization of the Monsalvat School of Comparative Religion, perhaps the first educational movement in the world exclusively devoted to the comparative study of religious ideas. The director, Dr. Lewis G. Janes, for many years president of the Brooklyn Ethical Association, and now the director of the Cambridge Conferences, has been identified with the Greenacre work from its first season. Courses of class lectures were given in the history and phylosophy of religion, the Vedanta philosophy and religion of India, the religion of Zoroaster and the Parsis, the religions of China, and unsectarian Christianity. This school will be continued during the coming season, with lectures on Buddhism, Hindooism, and Zoroastrianism, by native teachers, and the history and philosophy of religion and Christian origins by the director.

The Greenacre School of Music, established last year by Miss Mary H. Burnham, of New York, will also be continued next summer in a new building now in process of erection. The general lectures will be systematically arranged for the months of July and August (closing on the second of September) in weekly conferences upon the following topics: Peace and Arbitration, Business Ideals, Education, Evolution, Invention (especially emphasizing the progress of discovery and application in electrical science), Sociology, Psychology, Nature, Art and Comparative Religion. During the last week in July it is Miss Farmer's purpose to commemorate the fiftieth anniversay of her father's earliest work in the electrical field, involving the application of electricity to motor-traction—which has now become such an indispensable factor in the life of our great cities, and in solving the problem of suburban communication. The lectures of the conference during this week will commemorate different phases of progress in electrical science, and there will be an exhibition during July of interesting material illustrating the earliest attempts at motor-traction by means of electricity, and the subsequent evolution of this method of transportation. We understand that Miss Farmer has been assured of the co-operation of the Patent Office at Washington in obtaining material for this exhibit, from which a few early models will be taken. The loan collection will in the main be a graphic one. Any person possessing models, drawings, or any portable material, bearing upon this subject, and willing to permit its use in this exhibition, will confer a great favor upon Miss Farmer by communicating with her as early as possible, at Greenacre, Eliot, Maine.

The American Institute of Electrical Engineers, of which her father was an honorary member, the only American, therefore, elected, has decided to join in this interesting commemoration meeting by holding its annual meeting during the week beginning July 26 at Eliot. New cottages and dormitories are in process of erection, which, with the usual accommodations at the Greenacre Inn, and the fine hotels at Portsmouth and Newcastle, easily accessible by rail and carriage or by a steam launch plying on the beautiful Piscataqua, will afford ample accommodations to all who wish to avail themselves of this rare opportunity.

It is understood that in this noble enterprise at Greenacre Miss Farmer is carrying out substantially a long-cherished purpose of her large-hearted father and her noble mother, his life-long companion and inspirer in all his work.

He entered with enthusiasm into all his daughter's plans with regard to Greenacre and looked forward with joyful anticipation to the opportunity which it would give to call together in friendly conference the older and more experienced members of the electrical profession and the younger men, to whom the science open up such alluring vistas, with the purpose of emphasizing the power which resides in high ideals and impersonal work.

It is a happy chance indeed which permits the electricians of the United States, and their guests from abroad, at the British Association meeting, to participate in this most deserved and appropriate tribute to the memory, achievements and sterling character of one whom they delight to honor as a pioneer and master in the department of applied science to which their lives and labors are devoted.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

It is proposed to hold a subscription dinner, on the occasion of the annual business meeting and election, which occurs on Tuesday, May 18. The price of the dinner has been fixed at $2. In addition to the routine business of the meeting, a paper will be presented by Dr. Alexander McFarlane, and the paper on "The Synchronograph" presented at the meeting of April 21, will be taken up for discussion. It is the intention to call the meeting for 4 p. m., and adjourn for dinner about 7 o'clock.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. G. F. Porter, secretary of the association, says: "A great many inquiries are being received at this office regarding exhibits at the coming Niagara convention. For the benefit of those desiring to make an exhibit,I will state that no exhibition will be held under the auspices of the association; but from the tenor of our correspondence and personal interviews, we learn that many exhibitions will be made by our associate members in the parlors and rooms of the hotel."

NEW YORK ELECTRICAL SOCIETY.

At the annual meeting of the New York Electrical Society, which will take place at Columbia University on Thursday, May 20, some entirely novel features in the development of the thermopile will be demonstrated, with practical illustrations by Mr. H. Barringer Cox.

TELEGRAPHIC HISTORICAL SOCIETY OF NORTH AMERICA.

The third annual meeting of the Telegraphic Historical Society of North America was held in Washington, D. C., on the 5th inst., and the report of the proceedings and the papers presented on that occasion, show that in the short time the society has been in existence, it has become established on a firm and practical basis. Gov. Cornell was president during the first year; Mr. S. H. Kaufman, owner of the Washington "Evening Star," the second year, and at the last meeting the following officers were elected: President, Wm. B. Wilson, Pennsylvania Railroad, Philadelphia, Pa.; first vice-president, I. N. Miller, superintendent Western Union Telegraph Company, Cincinnati, O.; second vice-president, Francis W. Jones, Postal Telegraph Company, New York City; third vice-president, Wm. D. Sargent, Bell Telephone Company, Brooklyn, N. Y.; secretary and treasurer, George C. Maynard, Washington, D. C. Members of executive council: Charles Selden, superintendent Telegraph, B. & O. Railroad, Baltimore, Md.; J. Compton, superintendent Western Union Telegraph Company, Nashville, Tenn.; J. E. Pettit, Postal Telegraph Company, Chicago, Ill.; Wm. H. Young, Western Union Telegraph Company, Washington, D. C.

The society has adopted the novel and very useful method of publishing a book on the "instalment plan," its valuable reports and papers being printed and distributed to members, as soon as they are received, paged consecutively, and when enough mater to form a convenient volume is published, an index is to be furnished and the members will then bind the book to suit themselves.

Among papers already published, the most prominent is entitled "The Electric Telegraph in America," by Thomas D. Lockwood, of which two instalments have been printed, and the third and final instalment was read at the last meeting, and will be issued shortly. This history is written with Mr. Lockwood's usual careful and accurate manner, and will correct many popular errors. There is also a very valuable paper by the late Franklin L. Pope, on the "Genesis of the American Electric Telegraph," in which, that gentleman gives some newly discovered historical information, and corrects a misapprehension regarding statements made in an article written by him, for The Electrical Engineer in 1889, while he was its editor. A most excellent biographical notice of Mr. Pope, with a portrait, is also published.

At the meeting recently held, papers by George Kennan, J. B. Yeakle, Henry A. Reed, Wm. H. Young and Vice-President Miller were presented and discussed. The latter, giving a detailed historical sketch of the telegraph business in Cincinnati and vicinity, from the day the first line reached that city, contained an account of the pioneer work of J. D. Reed, Thomas T. Eckert, L. C. Weir, Dennis Doren, C. H. Summers, Geo. B. Hicks, M. C. Bristol, Anson Stager, S. P. Peabody, Dick Duncan and many other telegraph men who have become famous.

The Historical Society is continuing work of this character, and a number of its members are writing the history of other localities. Their sketches will be added to the society's publications from time to time.

REPORTS OF COMPANIES

BELL TELEPHONE OUTPUT.

The instrument statement of the American Bell Telephone Company for the month ended April 20 is the second largest in the company's history, the largest being a year ago. The net number of instruments put in lessees' hands was 13,181, making 45,579 instruments for four months. The comparative exhibit follows:

Month of April 20.	1897.	1896.	1895.
Shipments	20,426	21,525	18,794
Returned	7,245	6,330	6,253
Net output	13,735	15,195	12,541
Since Dec. 20.	1896-97	1895-96	1894-95
Shipments	73,735	76,518	50,157
Returned	28,156	28,462	25,225
Net output	45,579	48,056	24,932
Instruments in use	818,206	723,032	607,438

ANNUAL REPORT OF THE ELECTRIC STORAGE BATTERY CO.

President W. W. Gibbs has issued the following report to the stockholders of the Electric Storage Battery Co.:

The officers of the company submit herewith statement of the affairs of the company for financial year ending December 31, 1896;

Gross sales		$646,318.62
CONTRA.		
Cost of materials, labor and all factory charges	$362,142.21	
General expenses, including main and branch offices, commissions, legal expenses, taxes and interest.	142,178.09	
		504,320.30
Profit over all operating expenses		$141,998.32
Income from royalty and investments		6,801.28
Total		$148,799.60
Less interest on bonds		13,737.50
Net profit		135,062.10

As a means of comparison with the previous year, the following were the principal items:

Gross sales for 1896	$646,318.62	
Gross sales for 1895	328,231.40	
Increase of 1896 over 1895	318,087.22	or 96.90%
Income outside of manufacturing, 1896	6,801.28	
Income outside of manufacturing, 1895	2,218.48	
Increase of 1896 over 1895	$4,582.80	
Net profit, 1896	$135,062.10	
Net profit, 1895	2,982.40	
Increase of 1896 over 1895	$132,079.70	
Manufacturing cost, 1896	$362,142.21	
Manufacturing cost, 1895	247,938.54	
Increase of 1896 over 1895	$114,203.67	or 46.06%

You will notice that while gross sales for 1896 have increased 96.90%, the manufacturing charges have only increased 46.06%. The percentage of manufacturing cost to total output for 1896 was 56.03%. Same charges in 1895 amounted to 75.54%.

Up to the 31st of December, 1896, there has been expended in various demonstrations and applications of the use of storage battery, the sum of $41,408.75; this will be charged off to profit and loss. This is not a current expense, and it will not be necessary for the company to make any further expenditure in this direction. The various prominent applications of the battery made during the past year have demonstrated its commercial value in every respect.

The general expenses of the company, aggregating $142,-017.09, will not be materially increased if the company's business was more than doubled, in which event it will be clear that the proportionate profit will be largely increased.

PERSONAL

MR. FRANK J. SPRAGUE has received the contract for the equipment of the South Side "Alley" Elevated Railroad, of Chicago, with electric motors. This includes 120 cars, each of which will be equipped with two motors of 50 horse power each, thus making each car an independent unit. The first six cars are to be ready by July 1, and the remainder to follow in short order.

MR. T. A. EDISON has paid a visit to Toledo, O., and to the shops there which make a specialty of ore shoveling and crushing machinery.

MR. D. W. PEABODY has been elected general manager of the Fenton, Mich., Electric Light and Power Company.

MR. S. C. NORMILE has been reappointed superintendent of the Binghamton (N. Y.) Electric Company. He held the position for several years.

MR. D. THOMSON, of the Ithaca (N. Y.) Electric Railway interests, has gone to Hannibal, Mo., representing Eastern capital which has bought up and will extend the street railway system, building a new power house.

MR. J. A. JOHNSON, president of the Gisholt Machine Co., Madison, Wis., who was a member of the delegation that visited South America under the direction of the National Association of Manufacturers, has issued a very interesting illustrated pamphlet on his trip. It is well worth reading, for many reasons. Copies can be had on application to the Company.

MR. P. W. JOHNSON, manager of the Western Union Telegraph Company, at Lynn, Mass., has been making some improvements in the telephone, and is connected with some capitalists who propose to give the city a competing telephone service.

OBITUARY

MR. E. E. WINSHIP, JR., electrician of the light and power plant at Circleville, O., was scalded to death on April 29 by the bursting of a steam pipe.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

By MAX OSTERBERG.

Dynamos and Motors:

DRIVING ALTERNATORS IN PARALLEL.—An editorial notice refers to the new station at Wandsworth, England, where two "Universal" engines driving alternators have been tested together, running parallel. They are single crank engines. The installation is said to be a complete success.—Lond. "Elec. Rev.," March 26, '97.

MULTIPHASE INDUCTION MOTORS.—By A. C. Eborall. Author points out two reasons why multiphase motors have not been more extensively used in England, namely, that the demand for electrical power is very small, and secondly that in England this type of motor has never had a practical trial and consequently not had a chance to show its good qualities. He points out their many advantages and explains in a practical way their working.—Lond. "Elec. Rev.," March 26, '97.

Electro-Chemistry:

ON THE ELECTRICAL RESISTIVITY OF ELECTROLYTIC BISMUTH AT LOW TEMPERATURES AND IN MAGNETIC FIELDS.—By Profs. Jas. Dewar and J. A. Fleming. A course of experiments which was carried on in regard to measuring the resistance of pure bismuth wire when placed transversely in a magnetic field. The following conclusions were arrived at, namely, that the resistance is increased and for every temperature below the normal (20. degs. C.) there is some particular strength of the transverse field which just annuls the effect of cooling and brings the resistance of the bismuth back again to the same value it had when not cooled and not in any magnetic field. There are also several other experiments given accompanied by some curves.—"Electricity," March 24, '97.

Lighting:

FAULTS IN ARC LAMPS AND HOW TO FIND THEM.—The writer describes the different styles of arc lamps and their construction and the different systems which are used, pointing out the difficulties that arise and how they may be overcome. He also described the faults of arc lamps.—Lond. "Elec. Rev.," March 19, '97.

ELECTRIC LIGHTING OF COUNTRY HOUSES.—By A. H. I. Graham.—A detailed description of the different systems employed in private plants and the many different uses electricity is put to.—Lond. "Elec. Rev.," April 2, '97.

HIGH VOLTAGE LAMPS AND CENTRAL STATION PRACTICE.—By G. L. Addenbrooke. Mr. Addenbrooke gives an account of the use of these lamps in central station practice with a list of English stations using them.—Lond. "Elec. Rev.," April 2, '97.

Miscellaneous:

PREVENTION OF ELECTRICAL FIRES.—By F. W. Bathurst. This article is devoted to the subject of the way wiring is done in Europe, especially in England, pointing out the many very bad rules that are enforced and how they can be remedied.—Lond. "Elec. Rev.," March 19, '97.

LIGHTNING RODS.—Major D. P. Heap, U. S. A., points out three qualities which a good lightning rod should possess: Ease of discharge, first-rate conductivity throughout its entire length, and excellent ground connection. He then goes on to show how they should be set and where they should be placed.—"Elec. Rev.," April 14, '97.

Power Transmission:

THE TRANSMISSION OF POWER TO LONG DISTANCES BY ALTERNATING CURRENTS.—By W. B. Esson, M. I. E. E. Paper read before the Soc. of Arts. Author divides the subject as follows:

Generators.	Line.	Motors.
1. Single-phase.	Two wires.	Synchronous or non-synchronous.
2. Two-phase.	Four or three wires.	
3. Three-phase.	Three or four wires.	
4. Monocyclic.	Three wires.	Non-synchronous.

He then goes into detail comparing the relative values of the different types of generators, then discuss the line insulation, and closes the section with a detail of cost of line wire to transmit 300 horse power to various distances at various pressures. Lond. "Elec.," April 2, '97.

Roentgen Rays:

BECQUEREL RAYS.—An article by M. Becquerel in relation to rays emitted by uranium and more especially with their power of discharging electrified bodies, including the uranium which emits them. Uranium discharges electrified bodies at any potential in air. The tests were made by the use of the gold leaf electroscope. The writer proved that the air surrounding the uranium plays a prominent part in these discharges just as does the air traversed by X-rays. The rates of discharge are roughly proportional to the square root of density of the air or their gas. The course of the discharge is very similar to the cooling of a hot body.—From Lond. "Elec.," in "Electricity," March 31, '97.

ROENTGEN RAYS AND THE SOFT TISSUES.—Messrs. Remy and Contremoulin have lately applied the X-rays to anatomical study. With the aid of chemical preparations they have put the muscles, ligaments, and tendons of dead bodies, both of men and frogs in such condition that they have given radiographic images. The muscles are marked by bundles of longitudinal fibers very clearly outlined.—"Elec. Rev.," April 14, '97.

THE TRANSPARENCY OF BODIES TO THE X-RAYS.—By E. Van Ankel in "Journ. de Phys.," with regard to the comparison of transparency of bodies to the X-rays and to heat the experiments of M. M. Meslaus, V. Novak and O. Sulc show that the presence of fluorine, chlorine and bromine and especially iodine in a molecule increases opacity to the X-rays. Certain facts quoted by the author show that the presence of halogens and of sulphur in the molecule increases the opacity both to X-rays and to heat.—"Elec. Rev.," April 14, '97.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 4, 1897.

Alarms and Signals:—

AERO-ELECTRIC WHISTLE. C. R. Alsop, Middletown, Conn., 581,802. Filed July 13, 1895.

A signal consisting of a suitable motor, a worm connected to the shaft, a worm-wheel meshing a lug carried by the worm-wheel, a lever operated by the lug and air pump having a sounding mechanism adapted to be operated by the lever.

AUTOMATIC FIRE ALARM. G. B. Riley, Kahoka, Mo., 582,093. Filed August 19, 1896.

Consists of a sensitive circular spring being such as to readily expand and contract by variation of temperature, whereby the arm contacts, with a point connected with the bell circuit.

Connectors, Conduits and Insulators:—

ELECTRIC CABLE. M. Guilleaume, Mulheim-on-the-Rhine, Germany, 581,715. Filed October 18, 1895.

Comprises one or more insulated conductors embedded in a mass of India rubber, such covering serving to take the place of the heavy lead sheathing usually employed.

Distribution:—

ELECTRIC TRANSFORMER. E. Thomson, Lynn, Mass., 581,873. Filed January 29, 1890.

An ironclad transformer, the laminated iron envelope having its laminae made each of two F-shaped sheet iron punchings fitting together from opposite sides of the coils.

Dynamos and Motors:—

ALTERNATING CURRENT MOTOR. B. G. Lamme, Pittsburg, Pa., 582,132. Filed October 30, 1895.

Comprises an armature having a distributed winding, a starting resistance normally in circuit therewith, a short circuiting device for the resistance surrounding the winding and means for moving the device into and out of direct engagement with the winding.

Electro-Metallurgy:—

PROCESS OF DEPOSITING METALS ON SILVER COATINGS. C. Schwabe, Berlin. Germany. Filed June 5, 1896.

Details of process.

APPARATUS FOR EXTRACTING PRECIOUS METALS. E. Motz, Brewermine, S. C., 582,077. Filed March 27, 1896.

A rotative drum adapted to receive the ore, a core arranged in the drum, metallic plates forming the positive and negative electrodes of an electric circuit and carried respectively on the drum and core, and an electrical connection for the plates on the core.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. M. S. Okun, New York, 581,997. Filed August 30, 1895.

A sliding carbon carrying rod and a carbon carrier at an angle to the rod, the co-operating carbon being held at an angle to the first mentioned carbon, and feeding devices for raising and lowering the carbon rod.

Measurement: -

ASTATIC ELECTRICAL MEASURING INSTRUMENT. A. Raps, Berlin, Germany, 582,090. Filed October 1, 1896.

An astatic galvanometer, a pair of suitable shaped cores made of magnetic unmagnetized metal placed at a greater distance from the stronger magnet of the astatic system than from the other.

ASTATIC GALVANOMETER. A. Franke, Berlin, Germany, 582,120. Filed September 29, 1896.

Comprises swinging system of astatic needles and, attached to it, a second adjustable magnetic system considerably weaker than the first system.

Miscellaneous:—

ELECTRIC CIGAR LIGHTER. H. M. Handshy, San Antonio, Tex., 581,718. Filed August 10, 1896.

Embodies an advertising device to be operated in conjunction with the lighter.

ELECTRIC GAS IGNITER. F. N. Pike, New York, 582,085. Filed July 8, 1896.

Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY. H. C. Reagan, Jr., Philadelphia, Pa., 581,769. Filed December 2, 1896.

Sectional underground conduit system employing a device operated by compressed air and electric motor for emerging the magnets carried by the car.

RAILWAY. R. C. Sayer, Bristol, England, 581,773. Filed April 3, 1896.

Consists of power conveyors on the rail, radial connectors on the wheel adapted to connect it with the conveyors on the rail, and teeth on the wheel to keep it in position.

CONTROLLER FOR ELECTRIC CARS. A. Schmid and H. P. Davis, Pittsburg, Pa., 582,102. Filed January 17, 1895.

A rotatable contact bearing cylinder, a shaft for rotating it, the shaft being detachably connected with the cylinder, and being longitudinally movable when disconnected.

Regulation:—

CONTROLLER FOR ELECTRIC MOTORS. H. P. Davis, Pittsburg, Pa., 582,114. Filed January 14, 1895.

For controlling the movement of mechanism driven by two electric motors comprising the following steps, connecting the motors in series with resistances, opening the entire circuit, coupling the motors in a parallel with resistances and cutting out the resistances.

METHOD OF AND MEANS FOR CONTROLLING ELECTRIC MOTORS. H. P. Davis, Pittsburg, Pa., 582,115. Filed January 14, 1895.

Similar to above.

ALTERNATING CURRENT REGULATION AND DISTRIBUTION. B. G. Lamme, Pittsburg, Pa., 582,131. Filed March 27, 1893.

Consists in putting into circuit one or more synchronous motors at or near points of translation and varying the counter electromotive force of such motors as to keep the current supplied at a minimum.

Switches, Cut-Outs, Etc.:—

ELECTRIC SWITCH. G. T. Eyanson, Philadelphia, Pa., 581,706. Filed March 21, 1896.

A quick-break knife switch.

ELECTRICAL FUSE CUT-OUT. W. C. Bryant, Bridgeport, Conn., 582,036. Filed March 1, 1897.

Details of construction.

SWITCH FOR ELECTRIC CIRCUITS. A. J. Wurts, Pittsburg, Pa., 582,111. Filed November 14., 1896.

A knife switch having a wedge-shaped blade and a stationary jaw terminal comprising two bundles of conductors.

ELECTRICAL SWITCH. J. A. Spiker, Grand Island, Neb., 582,149. Filed May 14, 1896.

Specially adapted for telegraph systems.

Telegraphs:—

TÈLEGRAPHY. C. F. Eaton, Jr., Santa Barbara, Cal., 581,815. Filed July 18, 1896.

Comprehends the employment of synchronous alternating current motors and instantaneous photography.

TELEGRAPHIC APPARATUS. C. F. Eaton, Jr., New York, 582,157. Filed December 18, 1896.

Utilizes one set of pulsations of an alternating electric current for disclosing the characters at a distant station and the opposite set of pulsations for controlling the pulsations of a local alternating current motor for actuating the several operating parts of the apparatus.

Telephones:—

SELECTIVE SIGNALING CIRCUIT, APPARATUS AND SYSTEM. G. W. Whittemore, J. A. Barrett, Brooklyn, N. Y., and W. M. Craft, New York, 582,107. Filed November 28, 1896.

Adapted for use on party line telephone systems.

LEGAL NOTES

DECISION IN FAVOR OF AMERICAN BELL TELEPHONE COMPANY SUSTAINING LEGALITY OF THE ISSUANCE OF THE BERLINER PATENT.

At Washington, on May 10, the United States Supreme Court gave out its decision denying the motion of the government to have the Berliner patent, No. 463,569, of Nov. 17, 1891, set aside on the ground of unnecessary and improper delay in its issuance, it having been filed in 1877, and further because the company had acquiesced and helped in the delay, in order to defraud the public of its rights.

The suit originated in the United States Circuit Court for the District of Massachusetts, where it was decided in favor of the United States. Upon appeal to the Circuit Court of Appeals for the First Circuit, this decision was reversed, and the contention of the Berliner claimants upheld. From this opinion the United States appealed to the Supreme Court.

Justice Brewer, in beginning his statement, said this was the first case in this court in which upon proofs an application had been presented to set aside a patent for an invention wrongfully issued. However, there was no doubt of the right of the United States to maintain such a suit. The question, therefore, to be decided was whether upon facts disclosed the relief ought to be awarded. He took up the difference between patents for invention and land patents, the principal difference, he said, being that invention patents do not cover something which belonged to the government before it was invented. Hence, in this case, the patent conveyed to Berliner nothing that he did not before have. The patent only gave him exclusive rights for a time as an inducement to make it public. Consequently the government has higher rights in a suit to set aside a patent for land than in a similar suit on a patent for an invention.

Taking up the question of delay in the patent office, Justice Brewer said the application was pending in the department for fourteen years, during thirteen of which the invention was the property of the Bell Telephone Company. Mr. Bell had invented the telephone, and as that patent had expired all the monopoly which attaches to it alone has ceased and the right to use it has become public property. But his apparatus was insufficient for public uses. Berliner's patent supplied the deficiency of existing patents, as he invented something by which, taken in connection with Edison's and Blake's inventions, Bell's undulating current could be made practically available for carrying on conversations at long distances. In other words the telephone used to-day is not only that of Bell, but of Edison, Blake and Berliner as well. Therefore the right to use the Bell patent alone would be a barren one, extending the telephone patent to the life of the Berliner patent.

Some delay was unavoidable in the patent office. An application for patent cannot be considered and determined on the instant. Hence there could be no complaint on the mere fact of delay, though there might be of its excessiveness. But, added the opinion, it mattered not whether the delay be reasonable or unreasonable, if the applicant is not responsible for it. If the fault was that of the patent office the applicant is not held blameworthy, and his legal rights are not affected. He cannot be punished on account of the delay or negligence of the tribunal before which he is presenting his suit.

With reference to the arguments on the subject of the continuance of the telephone monopoly, Justice Brewer repeated that there was no question that Bell's patent had expired, but it must be remembered that Berliner's rights were independent from those of Bell. If there should be a new invention upon the expiration of the Berliner patent the rights of its author could not be abridged to relieve the public. The inventor of the latest addition is entitled to full protection, and if the telephone company buys that invention it is entitled to all the rights which the inventor had. The court, he says, dissented entirely from the views urged by counsel that the applicant for a patent was a quasi trustee for the public, but held that an invention was the absolute property of its inventor. The government in order to make its case must establish affirmatively that the delay in the patent office was caused by the conduct of the applicant. It cannot rest on mere inferences, but must prove the wrong in such a manner as to satisfy the judgment before it can destroy that which its own agents have created. This requirement the government had failed to meet.

Continuing on this point, he said there was no testimony as to any corruption of the officers of the department by the defendants, or any attempt at such corruption. So far, indeed, as was shown, there never was an intimation made to a single official that he could profit by a moment's delay. All thought of wrong, therefore, may be put aside. Counsel for the government had tried to show that the fact that the applicants were not active in their prosecution was an evidence of fraud in view of the vast value of the invention, but this argument did not counteract the fact that there was no request for delay, but, on the contrary, the applicants had made at least one urgent request for action. Something more than the mere assertion of counsel was necessary to meet this fact. He considered at some length the charge of existence of a tacit understanding between the officials of the patent office, the People's Telephone Company, and the Bell Company that the patent office proceedings in the Berliner application should await determination of the litigation between the two telephone companies, involving the validity of the Drawbaugh patent, owned by the People's Company, but even if this was so, it did not anywhere appear that Berliner was a party to such an understanding. The difficulty was that the assertion was not proved. Indeed, Justice Brewer asserted that a case is seldom presented in which there is such a total failure of proof of wrong.

He said further that the testimony showed that the examiners in the patent office had acted in good faith, whatever is to be said of the wisdom of the course pursued by them. They supposed they were acting in compliance with the rules of the office, and out of proper regard for conflicting interests. It was not strange, when there was so much litigation, controversy, and uncertainty, that there should be delay in settling a minor matter in the patent office until there should be a final decision of the primary rights. It was easy to say that there should have been prompter action, but a wisdom born after the event is the cheapest of all wisdom.

The conclusions of the court on this branch of the case were:

First—That before the government is entitled to a decree canceling a mechanical patent, on the ground that it has been fraudulently obtained, it must establish the fraud by convincing testimony.

Second—That an applicant for a patent cannot be held responsible for the dilatory acts of patent office officials, unless the delay is brought about through his corruption.

Third—The evidence in this case does not tend in the least degree to show any such corruption.

Fourth—If the circumstances do not show that the delay on the part of the officials was wholly justified, they do make it clear that it was not wholly unwarranted.

Of the contention that a "patent isued Nov. 2, 1880, upon a division of the original application, covers the same invention as that covered by the patent in suit, and exhausted the power of the commissioner as to that invention," he said the patent of 1880 was for a receiver, while that of 1891 was for a transmitter. It was claimed that the two inventions were one, but the decision of the patent office was against this contention, and this judgment could not be reviewed in the present suit.

Remarking upon another feature of the case, the Justice said that, taking into consideration the influences under which the suit was started, there were indications that the purpose of striking down this patent was to give value to others, and that private competitors of the Bell Company are seeking to inspire a rival, not for the public good, but for the promotion of their personal interests.

He said that Congress had established the patent office, and had thereby created a tribunal to pass upon all questions of novelty and utility, and had given to that office exclusive jurisdiction in the first instance, with specifications of circumstances under which they might be reviewed.

It would seem that the government should be as firmly bound by the decision of its own tribunal as individuals. There was nothing inconsistent, he said, between this view and that propounded in the case of the United States versus the Bell Telephone Company. There might, he concluded, have been an error on the part of the officials as to the existence of power or a mistake in the instrument itself, sufficient to justify a decree canceling the patent. Also, the deviation of the proceedings between the application and the patent may be such as to justify the interposition of the Court of Equity; but it was not intended that the courts of the United States, sitting as Courts of Equity, could entertain jurisdiction of a suit by the United States to set aside a patent for an invention, on the ground of error of judgment on the part of the patent officials. Hence this question was not now open for consideration.

Judge Harlan dissented from the opinion. Judges Gray and Brown, it was announced, took no part in the case.

The claims of the patent are as follows:

1. The method of producing in a circuit electrical undulations similar in form to sound-waves by causing the sound-waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described.

2. An electric speaking-telephone transmitter operated by sound-waves and consisting of a plate sensitive to said sound-waves, electrodes in constant contact with each other and forming part of a circuit which includes a battery or other source of electric energy and adapted to increase or decrease the resistance of the electric circuit by the variation in pressure between them caused by the vibrational movement of said sensitive plate.

3. The combination, with the diaphragm and vibratory electrode, of a rigidly-held opposing electrode in constant contact with the vibratory electrode, substantially as described.

4. In a telephonic transmitter, a vibrational plate made concave for condensing the sound, substantially as set forth.

5. In a telephonic transmitter, a vibrational plate provided with one or more apertures, as and for the purposes set forth.

6. A speaking-telephone transmitter comprising a diaphragm or disk sensitive to sound-waves, combined with a rigidly-held but adjustable electrode in contact with the same, whereby the electric current is transformed into a series of undulations corresponding with the vibrations of said diaphragm.

WESTERN UNION AND RAILROAD WIRES.

Rush Taggart of New York, solicitor for the Western Union Telegraph Company, in the United States Court at Omaha, on May 2, asked for leave to make supplementary filings in the case of the United States against his company and the Union Pacific Railroad Company in the matter of separating the telegraph business of the defendants. The question before the court is the entering of a decree, in obedience to the mandate of the United States Supreme Court, divorcing the Western Union from the Union Pacific and compelling the latter to operate a telegraph line of its own for commercial purposes. The court took the matter into consideration.

It is the conjecture that the defendants are seeking only for time, hoping to defer the entering of the decree until after the contemplated sale of the Union Pacific, when possibly the necessity for the decree may be avoided by the ratification of the old contract by the new company and the making of a new contract.

THE STOCK MARKET

LARGER VOLUME OF TRADE.

As far as can be ascertained the volume of trade in many lines is larger, but spring business is still a disappointment. It is thought that this is due to tariff uncertainty more than anything else. The crop outlook west is encouraging.

In Wall street there has been a decided stir over the alleged rupture, or want of cordiality, between Mr. George Gould and Mr. Russell Sage—another case of the young Emperor and his Bismarck. The effect of these rumors on Western Union is plainly seen in sales of 89,037 shares with a decline to 75 and closing at 76. General Electric is almost stagnant, only 1,427 shares being sold, around 31. American Bell Telephone was also dull with sales of 864 shares and a decline to 221½ from 223 the previous week.

COPPER.—Sales are reported of Lake Superior ingot at 11 cents, electrolytic wire bars at 10¾ on actual sales, and 10½ for casting stock.

ELECTRICITY IN THE ARGENTINE.

The export department of one of the leading electrical companies has, according to its managers, shipped more electrical machinery and apparatus to Buenos Ayres during the last month than in any other previous month in the record of the company. It is due to the activity in which electricity is being used in the Argentine. In electrical engines of the smaller sizes, together with dynamos, the shipments reached $32,000. In other apparatus for electrical uses their sales to Buenos Ayres, not only for that city but for distribution throughout the republic, were $64,000. German and English manufacturers are endeavoring to capture some future orders by giving unusually low prices, and it is quite likely that in electrical sundries their efforts will meet with some success, but it is doubtful that in dynamos and engines much will go to the other side.—N. Y. "Jour. of Commerce."

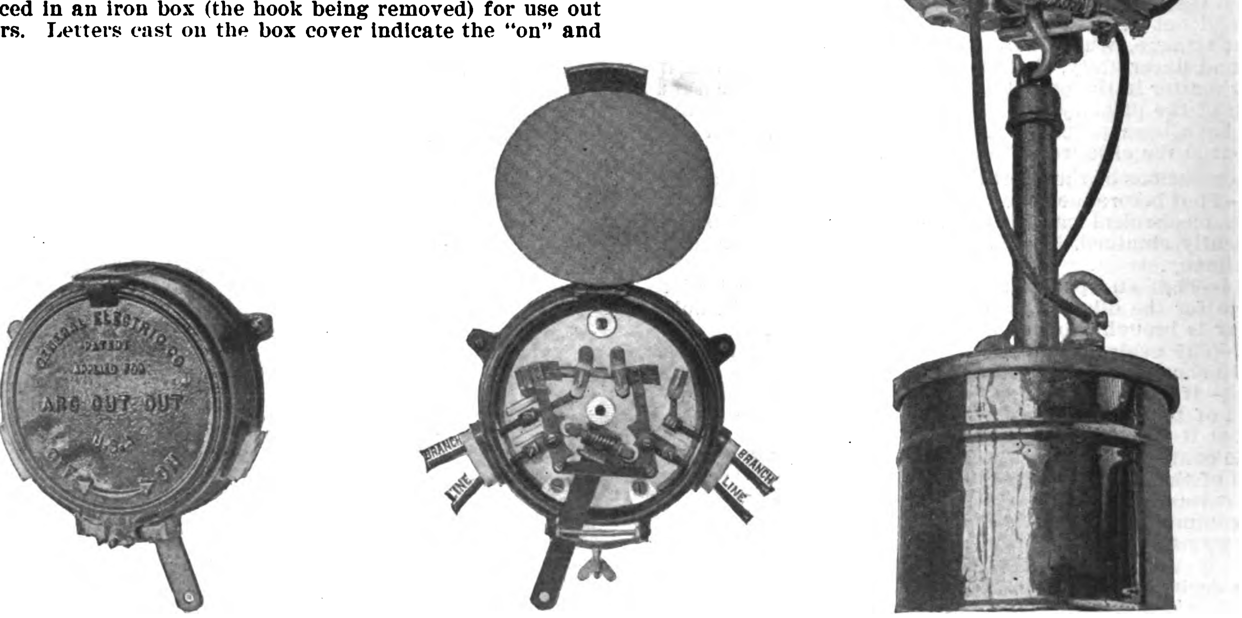
TRADE NOTES & NOVELTIES

G. E. PORCELAIN CEILING BOARD AND ARC CUT-OUT.

THE accompanying engravings illustrate two important adjuncts for use with arc lamps; the arc ceiling board and arc cut-out. Early practice allowed the use of wood in the construction of these appliances, but experience has shown the wisdom of making them entirely of incombustible material.

The bases are made of best quality of glazed porcelain and cast brass is used for connection parts. The lamp is suspended from a hook in the ceiling board and the lamp leads are attached to easily accessible connectors in the manner shown. The arc cut-out is a substantially built, quick break, double-pole, double-throw switch, making an absolute cut-out on both sides of the lamp circuit. A cam and spring action make it impossible to hold the switch at any intermediate point between "on" and "off" so that the current is never open on the line.

This cut-out may be used as a ceiling board, in which case a hook for hanging the lamp is attached to its center, or it may be placed in an iron box (the hook being removed) for use out of doors. Letters cast on the box cover indicate the "on" and "off" positions of the switch. These appliances are made by the General Electric Company of Schenectady, N. Y.



FIGS. 1 2 AND 3.—G. E. PORCELAIN CEILING BOARD AND ARC CUT-OUT.

SHEEHAN & HEWITT.

Sheehan & Hewitt is the name of a new electrical engineering firm which has been formed with offices at No. 14 South Water street, Newburgh, N. Y. Mr. William M. Sheehan, the senior member of the firm, has been in the electrical business for years, having been electrician and manager of the old Newburgh Electric Light and Power Company for some years. Later he established and managed the Hyer-Sheehan Electric Motor Company, from which firm he withdrew about a year ago. Mr. Hewitt is a graduate of Dartmouth College, where he took the degree of Bachelor of Science. Later he took a two years' post-graduate course at Cornell University under Prof. Ryan, and received the degree of Master of Mechanical Engineering. For the past two years Mr. Hewitt has been with the Hyer-Sheehan Motor Company, but retired from that firm May 1. The new firm will do engineering and construction work, paying especial attention to electrical work. They have already received some good contracts, and their extensive acquaintance and knowledge of their business would bespeak for them a large measure of success.

WESTERN ELECTRIC FAN MOTOR.

The handsome fan motor catalogue recently issued by the Western Electric Company has now reached its third edition. The Western Electric Company claim to be the largest manufacturers of fan motors in the United States and every one interested in fan motors should have one of their catalogues. The Western Electric Company guarantee their motors. Before shipping each motor is thoroughly examined, and every 110-volt motor is tested upon 220 volts, every 220-volt motor is tested upon 500 volts, and every 500-volt motor is tested with 1,000 volts. The demand for high class motors is met in these standard designs.

AMERICAN ELECTRIC TELEPHONE CO.

The American Electric Telephone Company, South Canal street, Chicago, report that their business is very good, and now that they are settled in their large new quarters they are in a position to supply all orders entrusted to them with the utmost promptness. Their new Express switchboard is the latest departure in that part of a telephone outfit, and they claim that it is the most rapid switching device ever constructed. Each drop and jack is self-contained in a hard rubber case, and can be removed and replaced in the board in the space of one minute without disturbing a single connection, and each drop indicates whether a line is working properly. For their new American solid back amplifying transmitter, they claim that it is the most powerful that has been produced. It is especially built for long and severe lines, and is said to be unequaled for volume of voice transmission, distinctness of articulation, exact reproduction of articulate sounds, and durable qualities. The American Electric Telephone Company have an attractive exhibit at the Tennessee Centennial Exposition, Nashville, Tenn.

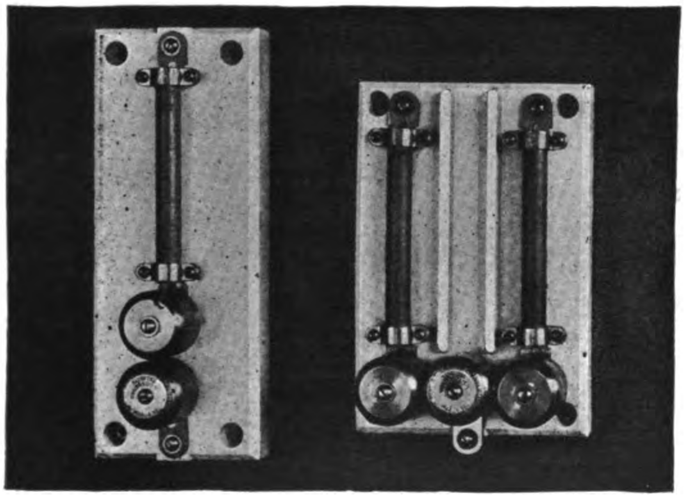
GOOD SALES OF RIDGWAY ENGINES AND DYNAMOS.

The Ridgway (Pa.) Dynamo and Engine Company report the following orders, all received within the past few weeks: One 12 x 23 x 18-inch compound condensing engine, for Ithaca Street Railway Company, Ithaca, N. Y. (second order); one 8 x 10-inch automatic engine, direct connected to a 25-k. w. Thompson-Ryan generator, for the Hart Memorial Library, Troy, N. Y.; one 15 x 16-inch engine, for the Southwestern Coal and Improvement Company, Parsons, Kan.; one 11 x 12-inch engine, for the Keystone Coal mining Company, Lawsonham, Pa.; two 14 x 14-inch engines, direct conected to two 75-k. w. Thompson-Ryan generators, for Cambridge Springs Company, Cambridgeboro, Pa.; two 15 x 16-inch engines, direct connected to two 100-k. w. generators, for the Metropolitan Theatre, Buffalo, N. Y.; two 250-horse-power engines, for the Berwind-White Coal Mining Company, Osceola Mills, Pa.; one 9 x 8-inch engine, direct connected to 20-k. w. generator, for the North Texas Bank Building, Dallas, Tex.; one 6 x 6-inch engine, direct connected to 8-k. w. generator, for the Coronado Apartment House, New York; one 80-k. w. belted generator, for the American Bridge Company, Chicago, Ill.

THE WIRT ALTERNATING CURRENT SHORT GAP LIGHTNING ARRESTERS.

A CAREFUL record of burn-outs due to lightning discharges discloses the fact that they invariably occur in connection with lines protected by arresters with long spark gaps or in electrical apparatus having poor insulation. Most of the electrical apparatus designed for operation on 1,000 and 2,000-volt circuits will barely stand a high potential test of 4,000 volts between the windings and frame of the machine. Arresters therefore, for use on these circuits should require a low potential to cause the current to pass across the spark gaps, separating the line from the ground connection.

The Wirt alternating current short gap arresters have been especially designed to operate effectively with very small gap spaces. The arrester for 1,000-volt circuits has but one spark gap of 1-32 inch between two metal cylinders 2 inches in diameter and 2 inches long, as shown in Fig. 1. One cylinder is connected to the overhead line and the other to the ground and a low non-inductive graphite resistance is placed in circuit. The combined action of the metal cylinders and non-inductive resistance prevents the heating of the cylinders when the lightning discharge passes across the gap making the gas which would enable the alternator to maintain the arc. The arc itself is extinguished by the reversal of the alternating current. This arrester is, therefore, not an arc rupturing device, but actually prevents the formation of an arc, the action being dependent upon the cooling effect of the large metal cylinders, which effect is increased by the introduction of a non-inductive resistance, and not upon any non-arcing property of the metal itself.



FIGS. 1 AND 2.—WIRT ALTERNATING CURRENT SHORT GAP LIGHTNING ARRESTER.

The arrester for 2,000-volt work, Fig. 2, has two gaps of approximately 1-32 inch and a low non-inductive resistance. This arrester will not hold a short circuit when connected directly across a 2,400-volt alternating current line, but will hold an arc when tested on a 500-volt continuous current line. This proves clearly that the reversal of the alternating current itself extinguishes the arc.

The Wirt arresters are designed for use on alternating current circuits at practically any potential, the standard list including an arrester for 15,000-volt lines. For circuits above 2,000 volts the standard 2,000-volt double-pole arrester has been adopted as a unit, several of these being connected in series for high potential work.

Arresters of this type have been adopted for the protection of the power line connecting Niagara Falls and Buffalo, at the power house of the Niagara Falls Power Company. An exhaustive test was recently made to determine the proper number of gaps and resistance for a 11,000-volt, 5,000-horse-power line. The arrester under normal action only showed a small arc about as large as a pin head between the cylinders. After many successful tests, the proper number of gap spaces was ascertained to be 14, with a wide margin of safety. The gap spaces are each 1-32 inch.

Arresters of this type are now standard with the General Electric Company, for all alternating current work, and a large number are already in service protecting long-distance transmission power lines having a working voltage as high as 15,000 volts.

WHAT IS SAID OF THE BERLINER DECISION.

As The Electrical Engineer goes to press, it is in receipt of the following telegram from the American Electric Telephone Company, of Chicago, as to its view of the Berliner decision: "It is simply a moral victory. The Berliner patent now adjudged as owned by the Bell Company has expired and never was valid. As it stands, it is very weak and can be easily beaten if suit is ever brought by the Bell Company, which is improbable. The Supreme Court decision on the question of fraud will be used by the Bell Company to dignify the patent and to further intimidate capital. Some people would stop eating bread if the Bell Company claimed a patent on flour. We will sell more apparatus and build more prosperous telephone exchanges than ever."

ADVERTISERS' HINTS

THE WARREN ELECTRIC AND SPECIALTY COMPANY, Warren, O., are selling 10, 16 and 20-candle-power lamps in barrel lots capped with Edison or Westinghouse base at 17 cents, and other bases at slightly differing prices.

THE C & C ELECTRIC COMPANY, New York, advertise their new six-pole generator in sizes of 30 kilowatts and upwards. It is made with all parts interchangeable, self-aligning and self-oiling bearings.

THE BUTLER HARD RUBBER COMPANY, 33 Mercer street, New York, the well-known manufacturers of hard rubber goods of every description, are making a specialty of Kiel's patented battery cells.

A. K. WARREN & CO., 451 Greenwich street, New York, advertise dynamo and motor brushes and illustrate them very handsomely. These brushes are made on economical principles and the waste is reduced to a minimum which amounts to nothing.

THE WESTERN ELECTRIC COMPANY, New York and Chicago, have a large variety of fan motors in their '97 models. They are wound for three speeds and are guaranteed to be as represented.

THE BRYANT ELECTRIC COMPANY, Bridgeport and Chicago, advertise "Paiste" switches at greatly reduced prices.

K. McLENNAN & CO., Marquette Building, Chicago, publish a fac-similie of the label which appears on all packages of Gale's commutator compound of which they have sold a great quantity to well pleased customers.

THE ELECTRICAL EXCHANGE, 166 South Clinton street, Chicago, advertise a fan motor at $11 which they claim to be of the highest grade and the lowest priced.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, are furnishing "Electro-Chemical" lamp coloring, which they say is quite as effective in use as genuine colored glass. They carry it in stock in green, blue, red, orange and frosting. One pint is sufficient for 200 lamps.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., have an iron roof for sale. It was originally designed for an iron foundry, but owing to the failure of the purchaser it is now offered at a bargain and is admirably adapted for any building for manufacturing purposes where a fireproof roof is desirable.

D. H. KULP, Marietta, Pa., advertises special facilities for manufacturing and financial aid for proper articles.

QUEEN & CO., Inc., Philadelphia, have brought out a self-regulating X-ray tube.

J. JONES & SON, 67 Cortlandt street, New York, manufacture panel boards, switches and switchboards. In their new panel board the number of joints is reduced to a minimum, is better in appearance than the old style and lower priced.

THE VIADUCT MANUFACTURING COMPANY, Baltimore, Md., guarantee the standard of their apparatus, which they manufacture in large variety for all telephone uses.

THE CENTRAL ELECTRIC COMPANY, Chicago, are reminiscent of the time "when we were idle boys," and as usual present a moral applicable to busy men.

THE WILLIAMSPORT WOODEN PIPE COMPANY, Williamsport, Pa., are always ready to supply wooden creosoted conduit in any quantity. There is over 500 miles of it in use in Philadelphia alone. Besides this they do a large business in octagonal poles.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., advertise their non-condensing compound engines and claim it to be the only compound engine which can be run non-condensing with economy.

THE BURR & HOUSTON COMPANY, 39 Franklin street, Brooklyn, N. Y., furnish gray iron castings for all electrical and machinery purposes.

NEW YORK NOTES.

COMMERCIAL CONSTRUCTION COMPANY, 1 Madison avenue, New York, have the contract for installing the new Bay Shore Electric Light Company's plant at Bay Shore, Long Island, N. Y. This contract includes the entire equipment—engines, boilers, dynamos, wiring, etc.

CHARLES ARTHUR HAGUE, 39 Cortlandt street, New York, is busy as consulting and designing engineer on several large plants which are now in process of construction. Mr. Hague installs and guarantees complete electric light and power plants as well as soliciting business as consulting and designing engineer.

HENRY F. NOYES, solicitor of patents, 35 Liberty street, New York, reports a good business. A larger number of applications for patents have been made the past three weeks than any time previously.

ELECTRICITY IN BELTS.—Some time since an engineer in a large factory called the attention of a visiting expert electrician to the electricity in a big driving belt, and was quite surprised when the expert informed him that the electricity was caused by the belt slipping. The expert added that it was simply a wasting of power and could be prevented by applying Dixon's Traction Belt Dressing, made by the Joseph Dixon Crucible Co., Jersey City, N. J. This dressing was applied and the electricity disappeared at once. Electricity in belts is not only a waste of power, but is also an element of danger of fire.

AMERICAN ENGINE COMPANY, of Bound Brook, N. J., have just begun shipment of their new direct-connected generating plants, in which the American-Ball engine is combined with their new line of six-pole generators. They are now installing a 75 kilowatt plant at 7 East Seventeeth street, New York, in the building of Deitsch Bros., and a 35 kilowatt plant in the building of the "Evening Wisconsin," of Milwaukee. In addition to this they have orders from the Philadelphia "Enquirer" for a 100 kilowatt plant; the Buffalo "Evening News" for a 35 kilowatt plant; the Phelps' Publishing Company, of Springfield, Mass., two 35 kilowatt plants; the New York "Tribune," a 75 kilowatt plant, and the World's Dispensary Medical Association, of Buffalo, a 25 kilowatt plant.

McLEOD, WARD & CO., 27 Thames street, New York City, report that they are quite busy with electric construction work. Among the many contracts recently awarded this firm may be mentioned those from the Central Railroad of New Jersey for five ferryboats and the steamers Monmouth, Sandy Hook and St. John's; the new Henry Heide candy factory, and F. L. Stetson's country residence at Ringwood, N. J.

WESTERN NOTES

SARGENT & LUNDY, Monadnock Building, Chicago, have, it is understood, closed arrangements to represent the C & C Electric Motor Company, in their territory. They will concentrate their energies in the motor line on pushing the well-known C & C power specialties, etc., and expect to make a fine showing.

H. B. CAMP & CO., of Aultman, O., have received the contract for the underground conduit for the Delaware and Atlantic Telegraph and Telephone Company of Wilmington, Del. The conduits will be terra cotta, laid in concrete, six feet deep in the soil, manholes at street corners. There will be four, six or ten ducts, according to location.

PHILADELPHIA NOTES

F. E. BAILEY & CO., of Betz Building, Philadelphia, who represent the Armington & Sims Engine Company, Providence, R. I., have closed among others the following contracts: For the Edison Electric Illuminating Company, Bellefonte, Pa., one 130-horse-power and one 150-horse-power Armington & Sims engines, to be fitted with new regulator. For the Midvale Steel Company, Philadelphia, one 170-horse-power engine of the new self-oiling type, fitted with new regulator. For the Altoona Electrical Engineering and Supply Company, Altoona, Pa., one 130-horse-power new type special railway engine with new governor. Also contract for a complete electric light and pumping plant for the Country Club at Harrisburg, Pa.

NEWTON MACHINE TOOL WORKS, Twenty-fourth and Vine streets, Philadelphia, Pa., report an increasing business. They are running full time with a large force. During the past month they have received an order for a heavy milling machine equipment for a Japanese railroad shop; a large duplex milling machine for the French government; vertical milling machines for Fraser & Chalmers, London. A few domestic orders include two rail ending machines for the Pennsylvania Steel Company, a large universal cold saw cutting off machine for the Lassig Bridge Company, Chicago, and one for Post & McCord, New York, besides many other orders for cold saw cutting off machines and heavy milling machines.

Vol. XXIII. MAY 19, 1897. No. 472.

THE HARMFUL EFFECTS OF THE X-RAY.

BY DR. F. S. KOLLE.

THE editorial in the last issue of The Electrical Engineer on Mr. Tesla's investigations of the harmful effects of the X-ray is a very timely contribution to the literature of the subject.

It seems to be a peculiar fact that these harmful results or effects are kept from the eyes of experimenters, whereas in my estimation they should be recorded for the benefit of all. Even Tesla reluctantly cites a case of dermatitis, as having occurred in his laboratory. If we cannot receive the valuable inferences of such experimenters as Edison, Tesla, Thomson, etc., then we cannot expect to advance in perfecting this scientific discovery. It should therefore be the duty of every one to record such effects from time to time, as he deems valuable, without further consideration or question whether or not such report might harm or decrease the revenue, derived from the new art. It is self-evident that we must all profit thereby in the end.

Tesla divides the effects of the rays into four divisions, namely, thermal, electrical, electro-chemical and mechanical.

The thermal effect he believes to be shown by the injurious results produced, resembling exposure to heat; although no idea of the degree of heat of the particles is given, yet he says: "If we consider the probable velocities only, they correspond to temperatures which may be as high as 100,000 degrees Centigrade." That this thermal property exists, is certainly shown by the heat effects, such as reddening, pain and even blistering, when a part of the body is injudiciously brought too near an active tube. If this is true, then we are at a loss to demonstrate the transference of the temperature by any present known method.

2. That the rays exhibit certain electrical properties is readily shown by their power of discharging electrified bodies, in an exceedingly short space of time. I consider this in favor of the theory of Tesla that the rays owe their property to minute material particles. This electrical property might have some influence on the skin or part of body exposed. If these local currents are so strong or destructive they certainly resemble the high frequency current effect of Tesla, as no actual shock is experienced by such currents, yet these direct currents of extremely high potential show no hurtful action on the body.

3. If we are to believe that the rays exterior to the tube are made up of material particles of whatever nature, then it is possible that these particles may carry with them or are composed of an electro-chemical substance, and here Tesla holds that with the rays coming from a tube, whose reflectors or impact plate were made of aluminum, no hurtful effects were noted, claiming just the contrary for tubes containing platinum electrodes. This is certainly a most interesting study, and need not necessarily surprise us. I have rarely used focus tubes whose impact electrode consisted of aluminum. The tubes as used in my laboratory contain the usual concave mirror of aluminum and the platinum plate. The fact that the one is dangerous or more so than the other, can only be ascertained, in my belief, by such men as Tesla, Edison, Thomson, etc. For such study, and to develop sufficient evidence, large and complicated apparatuses are required which few are fortunate enough to possess. The usual outfit, that is, one that will answer all purposes medico-surgically, need be put of from 12 to 14 inches spark capacity, and with such apparatus it would be quite impossible to obtain such results as Tesla gives us.

4. The theory of material particles holds good in the mechanical effects produced. It is quite likely that particles of whatever nature violently thrown against each other or the tissues of the body, must necessarily produce heat which may be sufficient to create tissue change. From the above conclusions of Tesla, we must always consider his theory of the nature of the rays, one or the other of his classifications would hardly hold, if other theories be advanced. Yet all these are plausible, and further results are eagerly awaited, as light in darkness, by thousands of experimenters. That the harmful action of the rays have been exaggerated, may be said to be true, when we consider the number of amateurs working in this enchanting art; most, with the exception of very few cases, would hardly have come to the ears of the eager public, who, believing all and considering none, only too readily condemn the entire work. And no wonder! It is but a short time ago I received a communication from Germany, where iodoform had been mistaken for pieces of glass in a man's arm and two operations were undertaken to remove same, where none actually existed. The radiogram showed a foreign body, but this happened to be the dressing applied to the wound in the arm. Such mistakes would not occur if responsible men undertook the work.

As the first experimenter in Brooklyn, and since February 4, 1896, I have had but one case of irritation of the skin and one of alopecia or baldness, resulting from exposure to the rays, during which time I have used tubes daily for hours at a time. The case of dermatitis, otherwise known as inflammation of the skin, was of mild type and under proper treatment abated in 12 days. The case of resulting baldness which is believed to be the first recorded in the world, was fully described in a previous number of The Electrical Engineer, and even here a complete recovery followed.

Yet, I have been called upon to treat numerous cases for other experimenters and in each case I was satisfied that the result was, to a great extent, due to too short a distance between the tube and part exposed. In fact, I have recently seen a case where a large gangrenous piece of the integument had to be removed. Such discharging and blistered wounds make up a great number of these painful affections. That they do not respond to treatment as quickly as diseases of similar nature, produced by other causes, is not true. No one would expect skin to grow under a layer of fine and gangrenous material. Instead, the acrid discharge retards and aggravates the conditions. Proper treatment is required to obtain a happy result.

But all this is not preventive. What shall be done as a prophylactic measure to protect the patient from such effects? Simply study your apparatus, know what it is capable of doing, know from experience the distance your tube should be placed from the body, know its value in emanations, and you will experience little trouble. A further preventive to protect the parts, as I have said in former papers, is the use of an unguentum, in the form of lanoline or vaseline, applied to the skin of the part to be exposed. This protects it from the powerful action of the ozone produced, which is known to be a powerful destructive agent of organic material. I have never felt any ill effects from the ozone generated by an induction apparatus; in truth, I feel better now than ever, and a slight post pharyngeal catarrh has disappeared during the last few moments of experimenting.

Moist dressings protect the parts as well as an ointment; this accounts for few bad effects in tissue by hospital radiographers, where injured members are usually dressed with moist dressings. Tesla uses a thin sheet or netting of aluminum connected to a condenser or the earth, as a collector of the electrical effects of the rays, being placed between the tube and the part exposed. That the interposition of such a metal products, can be readily felt by the amau-radiscope which I have used in the experiments with the blind (N. Y. Med. Journ., Jan. 16, '97). By using such screen the peculiar strain felt in the region of the frontal lobes of the brain is not felt as much as with the usual fluoroscope. I believe the marked anæsthetic effects noted by early experimenters, were due to the continued and monotonous vibrations of the rheotome and need not necessarily be accredited to the rays, although the highly vibrated etheric waves may have some appreciable effect on the auditory nerve.

Distance and time of exposure need careful study, and I would advise all beginners rather to increase the time than to shorten the distance and less harmful results will be attained. Until we receive further convincing proof of preventives the above precautions can be relied upon with comparative safety.

216 Seventeenth street, Brooklyn, N. Y.

X-RAY PICTURE OF AN ADULT BY ONE EXPOSURE.

BY WILLIAM J. MORTON, M. D.

AT the request of the editors of The Electrical Engineer I gladly furnish details in regard to the X-ray picture here reproduced in the hope that the applications of the X-ray in surgery may be aided.

The subject was a woman, 30 years of age, five feet four inches in height and weighing 120 pounds. She was in perfect health, well developed and muscular and particularly so about the hips. An emaciated subject from the hospital would no doubt have been much easier to picture, but the object was to demonstrate the applicability of the X-ray to the average person and to the entire organism as a complete whole, in cases where it is medically important to obtain such a view.

As is well known, X-ray pictures of the various portions of the skeleton, taken at successive exposures and patched together as well as may be, have been published, but besides the laborious nature of this method the chief objection to it has been that the parts on the different points do not in any sense accurately fit together. So far as is known to the writer, this is the first X-ray picture at one exposure of an adult skeleton.

The apparatus employed was that with which I have worked from the first (except when using a static machine), namely a 12-inch induction coil whose primary was supplied from the 117-volt Edison current of the street mains and "made" and "broken" by means of a break wheel causing about 5,000 breaks per minute. Both condenser and blower were employed to keep down the spark on the break wheel. At a revolution of the break wheel of 5,000 per minute, the coil affording a free discharge of sparks across a five-inch air gap, the number of amperes flowing through the primary circuit of the coil was 3 6-10 and the voltage at the terminals of the primary was 75. The Crookes tube employed was an ordinary focus tube; its vacuum at the start corresponded to a spark of two inches and gradually rose until at the end it corresponded to eight inches. The platinum anode was run at continuous red heat. The distance of the tube from the sensitive film was 4 feet 6 inches. The tube was run the first ten minutes steadily; then the current was turned off several times during a minute to allow it to cool. The total time consumed, including stoppages to take the picture, was 30 minutes.

A sensitive film 6 feet long by 3 feet in width, furnished by the Eastman Film Company, of Rochester, N. Y., was employed. Its development by the Eastman Company was procured by the firm of E. B. Meyrowitz, of this city, who also rendered other aid in regard to the preliminary mounting of the film. In making the attempt, I had hoped to be able to use two or more tubes at the same time, but preliminary experiment developed two obstacles to this course; the first was that each tube occasioned independent pictures whose outlines did not coincide and the second was the impossibility of keeping any two tubes, whether connected in series or in parallel, up to an equal degree of work. When in parallel, the current would quickly switch into one or the other in spite of artificial heating or cooling; when in series the tube with lowest vacuum limited the degree of current.

The resulting negative would have been better if longer exposure had been given, particularly about the region of the hips, but in this connection it is to be kept in mind that this region in ordinary subjects is extremely difficult to portray under the best of circumstances.

Granting that the intensity of the X-ray diminishes inversely as the square of the distance, it should take about twenty times as long to get a picture when the tube is 4½ feet from the sensitive plate, as it would when 1 foot from it. On the other hand, it was necessary to place the tube at least 4½ feet away to avoid the distortion corresponding to the casting of long shadows.

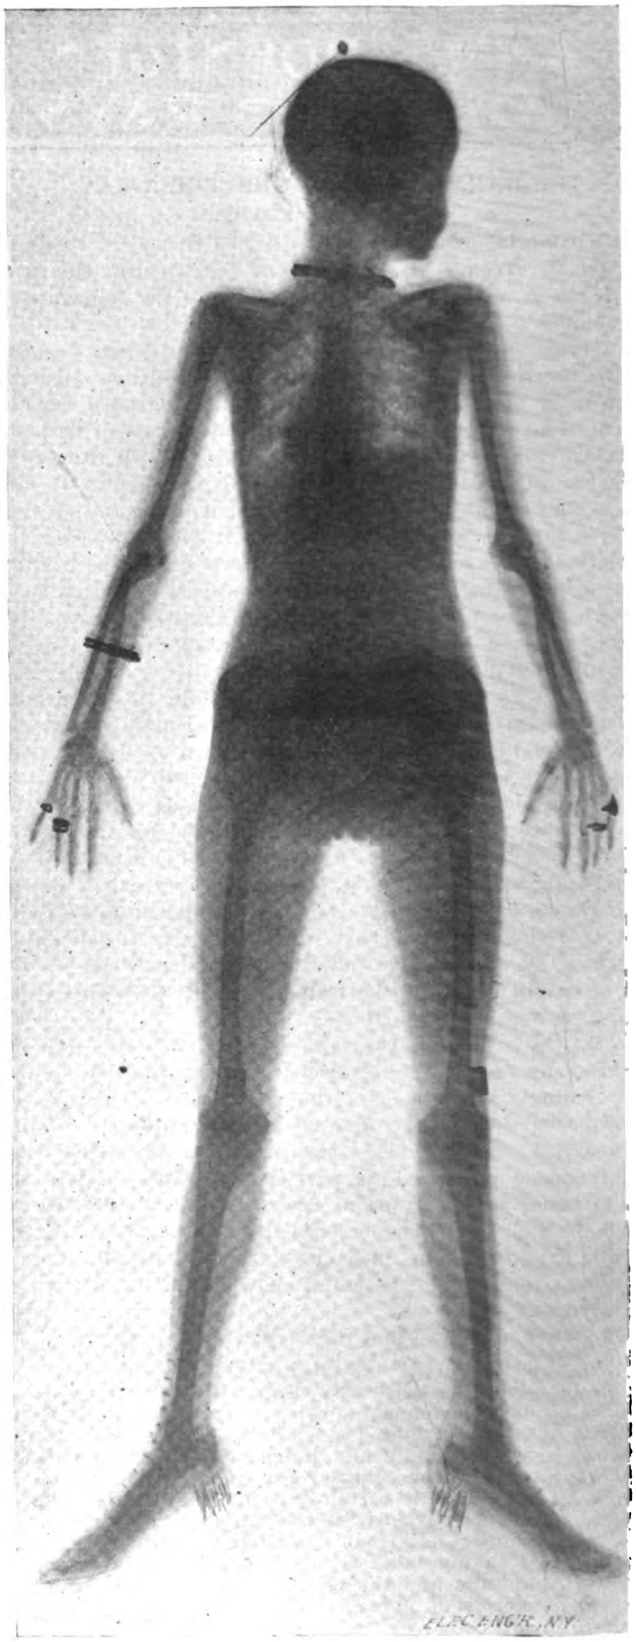
The degree of success attained in this experiment points to the conclusion that we may soon see Röntgen pictures of the entire adult skeleton at one exposure become a part of the ordinary curriculum of X-ray work in our hospitals as an important aid to diagnosis.

A ROENTGEN RAY TUBE WITH AUTOMATICALLY ADJUSTABLE VACUUM.[1]

BY H. LYMAN SAYEN, of Queen & Co.'s Laboratory.

THE most important and yet the most imperfect piece of apparatus that is necessary for the production of X-rays is the Crookes tube. It consists fundamentally of a cathode capable of focussing a stream of "radiant matter" upon a platinum plate, the whole being enclosed in a properly exhausted vessel.

Since the announcement of the focus tube in March, 1896, there have been few changes in the material arrangement of these parts. Many attempts, however, have been made to remedy one great defect which is inherent to Crookes tubes, and that is the gradual rise in vacuum subsequent to their constant use. I will briefly describe some of these methods and endeavor to show why they are inefficient.



ROENTGEN RAY PHOTOGRAPH OF COMPLETE SKELETON MADE WITH SINGLE FILM, 3 x 6 FEET, EXPOSURE 30 MINUTES. TAKEN BY DR. W. J. MORTON.

Many makers provide their tubes with a little bulb opening into the main tube and containing potassium hydrate or other material which is capable of giving off gas on being heated. When the vacuum gets too high, a spirit lamp is placed under the bulb and a small quantity of vapor is given off which lowers the vacuum the desired amount. It has further been suggested to use a resistance coil around the bulb and to regulate the heat by means of an auxiliary source of current.

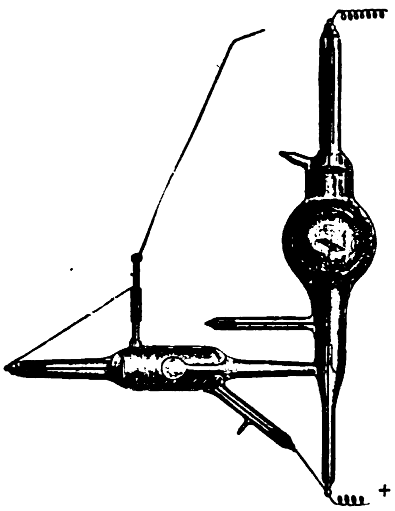
---

[1] Abstract of a paper read before the Electric Section of the Franklin Institute, Philadelphia, April 27, 1897.

Another scheme as suggested by Dr. William J. Morton, of New York, is to seal a small incandescent lamp on the main bulb, the two bulbs opening into each other, and to bring down the vacuum by passing an auxiliary current through the lamp filament.

Siemens & Halske, of Berlin, have recently put on the market a Röntgen ray tube in which the vacuum is adjusted in a most ingenious manner. A small bulb containing an internal electrode to which external connection can be made, is connected to the main tube. This bulb contains phosphoric vapors which have the property of condensing when traversed by an electric current. To raise the vacuum the electrode of the bulb and the cathode are connected to the induction coil. Warming the bulb causes the phosphorus to revaporize and lower the vacuum.

In all these schemes the vacuum may be varied over wide limits, and the life of the tube is increased to an indefinite extent, but as they all depend on the skilful manipulation of the operator, it is seldom that they accomplish the desired result. The vacuum in a Röntgen ray tube can only vary over very small limits, and being also dependent on the temperature of the tube, it is in a very unstable position. That is, if a tube starts to heat when running, the vacuum lowers and the tube takes more current due to the increased conductivity of the gas therein, lowering the vacuum still more, while a reverse condition of affairs takes place if the tube cools. So it will be seen that it is very difficult and often impossible to keep the temperature of the tube and to manage the regulating device to produce the desired result. One way of using these devices is to lower the vacuum the desired amount and keep it low by running with the platinum hot enough to keep the vacuum down.



Queen & Co.'s Adjustable Vacuum Tube.

The ideal regulating device should possess the following qualities: First; it should act immediately. Second; it should be independent of the temperature of the tube. Third; it should keep the vacuum where first put.

Having in mind the difficulties mentioned and the qualities desired, Messrs. Queen & Company authorized me to proceed in their laboratory with a series of experiments which have resulted in the device which I will now describe.

A reference to the illustration will make the operation of this device clear. A small bulb containing a chemical which gives off vapor on being heated and reabsorbs it when it cools, is directly connected to the main tube and surrounded by an auxiliary tube which is exhausted to a low Crookes vacuum.

In the auxiliary tube the cathode is opposite to the above mentioned bulb, so that any discharge through it will heat this bulb. This cathode is connected to an adjustable spark point which may be placed at any desired distance from the cathode of the main tube. The main tube is exhausted to as high a degree as possible in the first place while running hot, and the chemical in the small bulb is rid of enough of its gas to insure its remaining high at all ordinary atmospheric temperatures.

In operating, the induction coil is connected as usual to the main bulb. On starting the coil, the vacuum of the main tube being high, the resistance is also high and the current takes the path of the least resistance through the auxiliary tube, thereby heating the chemical in the small bulb. This will continue for a few seconds until a sufficient amount of vapor has been driven into the main tube to permit the current to go through it. After this only an occasional spark will jump across the spark gap to maintain the tube at the same vacuum. The vacuum may be set high or low by placing the spark point a considerable distance from or close to the cathode of the main tube.

I have here before you on the table a tube of this pattern connected to a large induction coil specially constructed by Queen & Company for Röntgen ray work. The coil gives a 14-inch spark and runs in a most quiet manner on the 110 volt circuit. By means of a resistance in the base I can regulate the current in the primary to any amount desired up to the limit of the coil. This fluorescent screen, behind which I have placed a thick book, will show any difference of penetrability of the Röntgen rays due to difference of vacuum.

On starting the current you see the main tube remains dark and the spark jumps across the spark gap. Almost immediately the large tube lights up. It is now possible to increase the current, and you can see that it is possible to get the platinum anode brightly incandescent without lowering the vacuum in the least, as shown by the brilliant fluorescence on the screen. I shut off the current and bring the spark points together; on starting the coil the main tube lights up at a very low vacuum; so low that there is no fluorescence produced at all.

The tube has now the characteristic appearance of running on an alternating current. The reason for this is that the resistance of the tube is so low that the secondary of the coil is practically short circuited, and by its mutual induction, decreases the self induction in the primary, allowing the current to rise more quickly on the make, producing considerable current in the secondary in the reversed direction. This effect is not so noticeable on battery circuits because the impressed electromotive force is not so high on the make. I will not run much current through the tube at this point, because it blackens the bulb considerably, due to disintegrated platinum when the platinum becomes cathode.

If I put a short spark gap in series with the tube and secondary you will notice that the alternating effect disappears and it is now perfectly safe to increase the current. I should advise all experimenters who desire to keep their tubes from blackening, that in using tubes where the platinum is the anode (and with the platinum the anode we get undoubtedly better X-rays), to use a similar spark gap in this manner. The sparking distance should be greater than the coil will spark on the make, and it is especially desirable where it is necessary to run on low vacuum with 110 volt primary.

On separating the spark points, you see the vacuum rises slowly in the main tube until the spark prefers to jump across the gap. The tube now runs quite steadily without flicker, a small intermittent spark being sufficient to keep the vacuum down.

I will now connect the coil to the heating tube only and run it lightly for a few seconds, so as to drive considerable gas into the main tube. On connecting again to the main tube it will be noticed that the vacuum is so low that the gas is simply a conducting stream between the terminals such as we recognize in a tube exhausted to a couple of millimeters of mercury.

Supposing we assume, after Crookes, that the vacuum necessary to produce X-ray effects is about one-millionth of an atmosphere (this is a low enough assumption at any rate); this bulb then contains enough gas to fill this whole hall at that high vacuum, so that the life of such a tube, barring misuse, should be practically unlimited. From even this most severe treatment, the tube rapidly recovers and is now working in its normal state.

I will conclude my paper this evening with a brief summary of the advantages which I think a tube of this kind possesses over the ordinary type. First, adjustable vacuum. It may be set at any vacuum desired, from one so high that no current will penetrate it, to one so low that the current would rather go through the tube than jump over a parallel spark gap of one-half of an inch. In a radiograph of the hand, for instance, it is desirable to use a low vacuum to secure the necessary contrast between bone and flesh, while in locating foreign metallic bodies in dense tissue, it is desirable to use a high vacuum. Second, automatic regulation. At whatever vacuum it is set it will remain so long as the coil is running without any attention whatever from the operator. Third, it will stand considerable energy without decrease of vacuum, consequently shortening the time of exposure necessary.

Prof. Arthur W. Goodspeed, of the University of Pennsylvania, has taken his best radiograph of the hip in three minutes with one of these tubes; he has also taken an excellent one in one minute. Dr. Wm. M. Sweet, with the tube adjusted at high vacuum, has located foreign bodies in the eye, the pictures being taken perpendicularly across the head with an exposure of thirty seconds. Fourth, a long lease of life.

X-RAY PALPITATIONS.

Paris doctors declare that X-rays produce violent palpitations of the heart. Drs. Seguy and Quenisset have experimented on their students and on themselves, and declare that when continued the palpitations are unendurable. They stopped them by placing a metal plate between the heart and the rays. They advise people who are not in perfect health to keep out of the way of the X-rays, or, at any rate, to protect their vital organs against them.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—X.

APPLICATION OF STORAGE BATTERIES TO ISOLATED PLANTS.—Continued.

BY JOSEPH APPLETON. (Copyright, 1897.)

Having thus stated the various functions of storage batteries as applied to isolated plants of the second class, we will now consider the methods of installation.

A somewhat different problem has to be solved in the installation of storage batteries in isolated plants of this class to that met with in the first application. The control or regulation of the discharge could be effected in the same manner, either by cutting out counter cells, or cutting in end cells as the voltage falls, but the same method of charging, namely, running up the voltage of the dynamo to the required point is not feasible, as the current required for charging the battery is only a portion, and usually a very small one, of the output of the machine.

To adopt the same method would mean that the entire output from the dynamo has to be generated at the higher voltage, that is, 110 to 150 volts, according to the conditions of charge, while the portion required for the load would have to be reduced to the normal working pressure of 110 to 115 volts. This would have to be done either by counter cells, which, besides being uneconomical, would be troublesome on such a large scale, or by end cells, which method is not recommended on account of the injurious effect which would result from the large current necessarily passing through them.

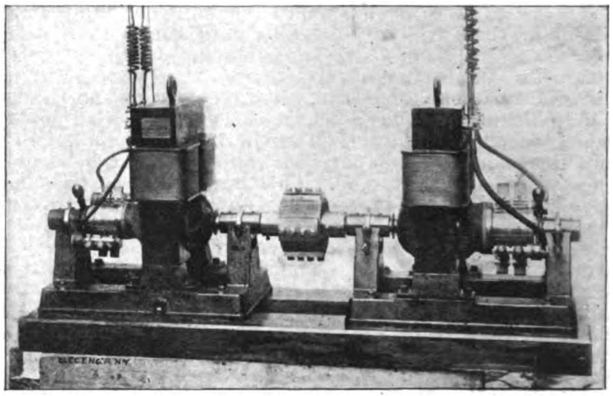

FIG. 35.—MOTOR DRIVEN BOOSTER.

One method occasionally used, but not the best, is to divide the battery into halves, and charge them in multiple, a resistance being used to cut down the voltage and regulate the charging current. The objections to this method is the necessity of some arrangement to regulate the charge through each of the two halves, and the loss in the resistance required for cutting down the voltage. For example: A battery of 60 cells on a 110-volt circuit would be divided into two groups of 30 cells each in multiple; the greatest voltage required for charging them would be 30 x 2.5 = 75 volts, leaving 35 volts or more to be absorbed by the resistance. The current would be twice the normal charging rate of the cell, there being two groups in multiple. This method is very uneconomical, but is sometimes used when the amount of current required for

charging the battery bears a very small proportion to the total output, and the loss is therefore hardly noticeable.

The best and most efficient method is to employ a small and supplementary dynamo or booster, so called because its function is to raise the voltage of the current required to charge the battery. The connections of this arrangement are shown in Fig. 34; the combination is really a small dynamo run in series with the main generators, but connected only to the battery circuit, and having a capacity only of the current required for charging the battery, and a voltage varying from 10 to 50 volts. This booster may be either motor or belt driven. Fig. 35 illustrates a motor driven booster in compact and convenient form. The field of the booster is separately excited from the bus bars of the installation, so that a steady field may be obtained independently of the varying voltage required from the machine. The voltage is raised by means of a rheostat in the field circuit.

At first sight this method may appear complicated and expensive, as it necessitates the use of another generator, but when it is considered that its capacity is very small, having a maximum voltage of only 50 volts, and the current capacity equal to the charging rate of the battery, this objection is easily dispelled, especially when the perfect flexibility of the system is realized.

When a storage battery is used for regulating the load in a generating plant in the case of elevator or similar service which is entirely fluctuating, a differential booster is used. The function of this machine is to control the working of the battery so as to meet the sudden fluctuations of the load; that is, to charge the battery when the load is light and to make the battery discharge when the load becomes heavy, thus keeping the load on the generating plant constant.

Fig. 36 illustrates the connections of this system. The booster in this case has two field windings, a series and shunt, which oppose each other, the shunt field magnetizing the booster so that it will generate current in the direction for charging the battery, and the series field magnetizing it in the opposite direction to assist the battery in discharging. The series winding is connected in the circuit which supplies the fluctuating current, as shown. When the load in this circuit is light the series field is weak and is overpowered by the shunt field which charges the battery. When the load is heavy the series becomes strong and overpowers the shunt field, causing the battery to discharge. By this means the generators can be run at a steady load, the entire fluctuations being taken care of by the battery under control of the booster. A rheostat in the shunt field, and a shunt across the terminals of the series windings, provide the necessary means of adjustment required to meet all the conditions of service.

This method of operation is ideal, as it enables the battery to act as a reservoir automatically and yet without any complicated relays or apparatus liable to get out of adjustment, depending entirely on the regulation due to changes in the magnetic field of the booster. With a properly designed and adjusted combination of this sort the voltage on the system can be kept constant in spite of the varying load, and the load on the generators maintained at a steady and economical point.

LIGHTNING EFFECTS AND THEIR RATIONALE.

BY FRANCIS W. JONES (Elec. Engr., Postal Telegraph Company.)

I HAVE observed in the accounts of the death or injury of persons by lightning for several years that lightning very frequently tears off the shoes and frequently throws them quite a distance. What is the rationale of this?

We are so well informed about X-rays and other abstruse phenomena that surely this strange freak of electricity can be explained. I inclose a few cases in point that at present seem well enough authenticated, as unchallenged, newspaper records:

1891.—South Sterling, N. J.—Gussie Ryan was killed by lightning, clothing torn from body and rubber shoes burned from her feet.

1892.—July 25th, Ottumwa, Ia.—Mrs. Fielder was injured, clothing torn from body.

1893.—Tinton Falls.—Mrs. Daniel Polhemus killed, buttons torn from her clothes and shoes torn from her feet.

1894.—August 3d, Sachuset Point, R. I.—Benjamin Anthony, wife and 3-year-old boy were struck by lightning in a carriage. Nearly all of Mrs. Anthony's clothes burned from her body. Mr. Anthony's rubber boots were melted from his feet.

1894.—Pinkney, Mich.—Boy 14 years old had his feet completely shattered.

1895.—April 10th, Port Jervis, N. Y.—Young child of Mrs. Kaas was struck, tearing off a shoe.

1895.—June 3d, Plowville, Berks Co., Pa.—Webster Ziegler killed while sitting in an arm chair on porch of hotel. His shoes were torn from his feet.

1895.—Red Hook, Brooklyn, N. Y.—Jeremiah Donovan killed; left sleeve of shirt torn to shreds, trouser leg torn away and both shoes ripped from his feet. The upper part of the left shoe had been cut off and the leather of the heel burned away, leaving only the shoe nails. The inner side of right shoe cut and burned.

1897, May 1, Lexington, Ky.—Mrs. Nanie Williams, wife of Howard J. Williams, a well-known farmer of Garrard County, was struck by lightning and instantly killed. She was sitting in front of the fire when the bolt struck the chimney, ran down it, and caused her death. The current entered her body immediately over the heart. It passed out into the floor, tearing a shoe from her foot.

TELEPHONY AND TELEGRAPHY

THE SYNCHRONOGRAPH.—A NEW METHOD OF RAPIDLY TRANSMITTING INTELLIGENCE BY THE ALTERNATING CURRENT.—III.

(Concluded.)

BY A. C. CREHORE AND G. O. SQUIER.

THE LINE.—It is generally understood that the line limits the speed of telegraphy. The limit is usually reached because of the distributed electrostatic capacity of the line rather than its resistance. The influence of the distributed capacity is to change the form of the wave as well as reduce its amplitude.

In order to test this system over as long a line as was available, the land telegraph and telephone lines upon the military reservation at Fort Monroe were joined in series, making about thirteen miles of iron wire having a resistance of 320 ohms. Not only was no difficulty experienced in transmitting and receiving messages over this line, but resistance was introduced making about 1,500 ohms total including the polarizing receiver coil of 390 ohms. This trial was at a frequency of about 200 complete periods per second. With the chemical receiver a coil of 10,900 ohms was used in the laboratory and the record was plainly received at a frequency of about 545 complete periods per second.

Conclusion.—When the extent of the transmission of intelligence at the present time is considered, and the direct influence which this service has upon the development of the world's progress, any proposition which promises to increase its efficiency should be received with consideration.

To better comprehend the volume of this service it is of interest to observe the statistics on the subject. These have been prepared from the United States mail service, the Western Union Telegraph Company, and the American Bell Telephone Company of the United States, and are exhibited in graphical form in Fig. 12.

It is noticed in general, that there is an increase in all departments of the intelligence transmission service from the earliest dates. The number of pieces of mail sent during 1896 was 5,693,000,000 which is the greatest amount ever sent in a single year. The greatest number of telephone messages on record for a single year is 757,000,000 in 1895. The largest number of telegraph messages was sent in 1893 and amounted to 66,000,000. Thus the greatest number of telegraph messages as compared with telephone messages is in the ratio of 1 to 11½. The greatest number of pieces of mail is in the ratio of 86 to 1 as compared with telegraph messages, or in the ratio of 7½ to 1 as compared with telephone messages. It is also seen that the cost of the mail service of the United States in 1896 was $90,626,000, or about $1.25 per capita. The greatest receipts for any year of the American Bell Telephone Company were in 1895 $16,400,000, about 25 cents per capita, while the greatest receipts of the Western Union Telegraph Company were in 1893 $24,978,000, about 35 cents per capita.

It appears, therefore, that the people of the United States pay for a telegraph service of about one-eighty-sixth the amount, about one-fourth of that paid for the entire mail service of the United States. It also costs one-and-a-half times as much for telegraph service as for the telephone service, although the number of telephone messages is about eleven-and-a-half times as great.

A conclusion to be drawn from the above general data seems to be that the people are willing to pay more in proportion for a kind of service like that of the telegraph than any other. From the point of serving the people, as well as from a business standpoint, it appears that improvement in this class of intelligence transmission is at present much to be desired. The present state of the art of telegraphy points to improvements along the line of automatic machine transmission.

It is of interest to inquire what effects a system of telegraphy capable of sending continuously 3,000 words a minute would have on the existing methods. To take a single example of the business between New York and Chicago, where about 40,000 letters are carried daily, it would require but two lines in continuous operation to handle the entire business. At present it takes three days to receive a business reply between New York and Chicago. This transmission by machine telegraphy could be accomplished easily the same day. It is thought that an effect of this would be to increase business transactions to such an extent that the total volume of intelligence transmitted would be augmented, rather than to diminish the business now done by existing methods.

The class of business which such a system would probably at first obtain would be the less urgent telegraph business of greater volume, such as the Associated Press dispatches and newspaper press reports.

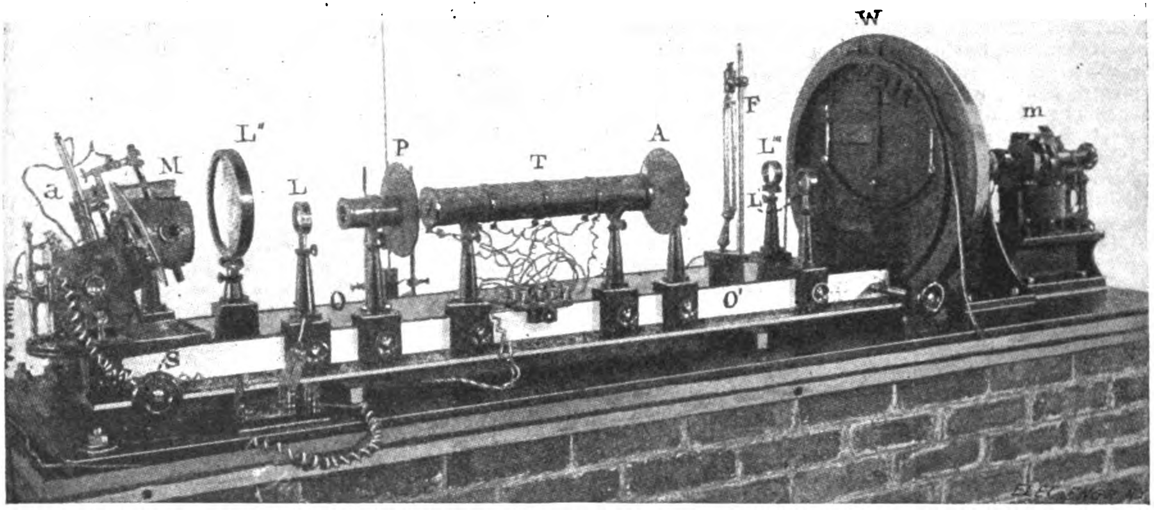

FIG. 11.--THE POLARIZING PHOTO-CHRONOGRAPH.
W, Wheel Holding Photographic Plate driven by motor; F, Arc Lamp; P, Polarizer; T, Tube; A, Analyzer.

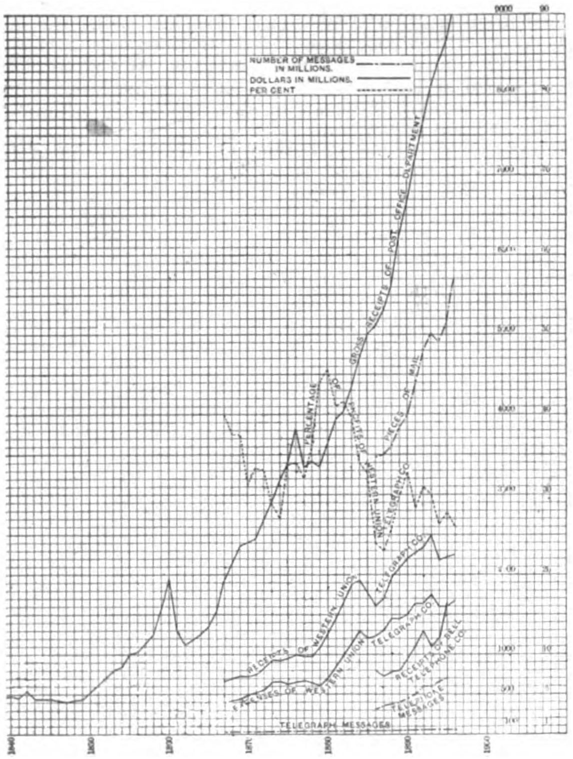

FIG. 12.

In addition to the above it is practicable to employ the line for a system of the ordinary quadruplex telegraphy at the same time. In trial experiments in the laboratory, particular instructions were given to the operator of the Morse instrument to observe if possible when messages were being sent by the alternating current, and absolutely no effect was detected.

A telegraph office of the future will probably present a different appearance from that which may now be seen in any of the large cities. At present in operating the Wheatstone system in this country, sending to long distances at the rate of 150 to 200 words per minute, both those who prepare the sending tape and those who translate the receiving tape are employés of the telegraph company and are near the sending and receiving instruments. If it requires about ten men to prepare tape, and as many more to translate it for a single instrument operating at 150 words per minute, it will require twenty times this working force for one of the rapid machine transmitters. Evidently changes would be required in the present methods to handle this business.

It is thought that a telegraph company of the future will fulfil a somewhat different function from the present ones. The company will own its wires and rights of way as now, but the tendency of the offices proper will be to transmit and receive letters already prepared rather than to undertake the preparation of the letters as well. The income of the company will be derived from the rent of its lines at a fixed price per minute, or a fixed price per hundred words. The service of the telegraph office then becomes like that of the post office, its duty being to receive and deliver letters already prepared, as the post office does. The difference between the two offices is in the manner in which this is accomplished. The telegraph office becomes a post office which employs an electric current in a copper wire to carry its letters instead of a railroad train.

It would be to the interest of such a company to seek that class of less urgent business now done by correspondence, rather than the class handled by the present telegraph companies, where the highest speed of delivery is expected. If one trunk line becomes established between large business centers, it will draw business from a surrounding area. For instance, if a line were established between New York and Chicago, and a person in Albany desired to communicate with Chicago or points beyond, it would be quicker to send the letter to New York for transmission over the trunk line to Chicago, and then by rail to its destination, than to send directly by rail from Albany. With a few trunk lines in successful operation it would not be long before they would be multiplied.

It is understood that these telegraph letters are sent by mail in envelopes in the usual manner, except that the envelope contains the prepared message ready to be sent through the transmitter, and thus the telegraph office becomes relieved of the preparation of the letters which is not strictly a part of its business. When the system comes into general use, business offices will have their own perforators, and it will become necessary for the operator to learn the telegraph alphabet as part of his preparation as a stenographer and typewriter. The opportunity to obtain a cheaper rate for prepared letters will act as an inducement to those employing a stenographer to add a perforator to their offices.

In the limited use of rapid automatic intelligence transmission at present, the sending and receiving records are made upon prepared paper in the form of tape. In the larger volume of business which is being considered here, it does not seem certain that tape would be the best form for the sending and receiving paper. It would be an advantage to have the letters received upon sheets of paper with the dots and dashes arranged in parallel lines.

Another point which must be considered is whether, with these systems, the induced currents from neighboring wires along the line or from any other cause will affect the legitimate signals materially, as has been at times the case with the Wheatstone system. In reply to this it can be said that these receivers for telegraphy are not necessarily more sensitive to small currents because they are rapid. On the contrary, they may be made to require as much current as is found desirable to rid them of the effects of outside influences, and at the same time retain the property of quick action in response to currents of the proper magnitude. In this connection it may be said that the utility of a single line wire becomes so great that more attention will be given in the future to the line construction and maintenance. If millions of dollars are invested in the construction of a single railroad, is it not as necessary to make the telegraph lines which carry important and profitable business as perfect in their construction?

The telegraph line of the future will comprise substantial poles carrying a few copper wires worked to their full capacity for transmitting electric signals. The cost of maintenance of such a line when once constructed will be little more than for an ordinary iron wire now used, while its carrying capacity for intelligence at 3,000 words per minute simplex will be about equal to 160 wires used for hand transmission simplex. By duplexing the line, the carrying capacity is doubled and becomes 6,000 words per minute, which is about equal to 160 wires worked duplex, or to 80 wires worked by hand quadruplex.

It is thought that the influence which the inauguration of a telegraph letter system would have upon the existing telegraph and telephone business would be to increase rather than diminish it. Each of these services has its own special field of usefulness but little affected by the others. A new field would be occupied rather than an old field supplanted. The present telegraph and telephone would still have their natural field of operation, even though the best hopes for a telegraph letter service are realized.

A single line capable of sending 6,000 words per minute between New York and Chicago, becomes a different kind of investment from a long distance telephone line where the number of words per minute with the fastest rate a speaker can talk is very slow in comparison, and the charge is $9 for five minutes' use of this line.

The application under government control of a rapid system of correspondence transmission such as has been outlined, operating in conjunction with the present postal system, by supplementing and relieving their service could hardly fail to prove of benefit to the people of the United States. This comes within the proper duty of the Post Office Department, and would be under the direct control of the Postmaster-General. The simplification in operation and expense which would result from uniting directly with the general post offices of large cities the telegraph letter service would soon be realized by the people and a better service insured.

The persistent efforts of Mr. Delany and the great system which he has developed are well known, and the ideas which he has advanced in regard to the applications of rapid systems are in the main in accordance with those stated herein.

A CLEVER PEN PICTURE OF HENRY C. PAYNE.

IN the Madison, Wis., "Journal" is a neat pen sketch, by Mr. H. Taylor, of Mr. Henry C. Payne, of Milwaukee, the well-known National Republican Committeeman and active manager of various electrical enterprises in Wisconsin, who was named recently for Postmaster General, and will probably be asked to take some other important office, perhaps a foreign mission:

"There was a good chance to see Henry C. Payne at his best before the Senate Committee on Corporations Thursday afternoon. He was arguing for the Bell Telephone Company as against its newer rivals. The 'Hypnotizer,' the Milwaukee 'News' styles him, and surely a 'more courteous self-poised, deferential, persuasive gentleman never pleaded for 'vested rights.' Mr. Payne does not storm or browbeat; he talks on in a quiet, reasonable way that would even undermine the judgment in a bad cause (if he could argue a bad cause) and when he does wax earnest, the style and voice indicate genuine indignation within. Few speakers so understand the possibilities of the human eyebrow. It is more expressive sometimes than a gesture. An interruption that seems to be unanswerable is met by a gentle, inquiring, almost pleading uplift of the eyebrow, while the busy brain behind hastens its resources. Again, Mr. Payne makes a clinching good point that must sink deep into the memories of the committeemen. Most speakers would show exultation. Not so Mr. Payne. He lets his hearers make the discovery! It is his part only to allow his eyes to fall to his notes carelessly, almost coyly. It is immense. Once only did he strike out to hurt, when a representative of a rival concern in the western part of the State interrupted him with a question as to how Mr. Payne's company spent its earnings. 'I should call the question impertinent coming from you,' replied the Milwaukee magnate. There was mingled rebuke and pain in the delicate, withering retort, and the face of the speaker indicated a hurt feeling, but no anger. The 'et tu Brute' of Julius Cæsar could not have been more pathetic and freer from bitterness. There was even a polite smile breaking later and the interrupter soon sought the floor to make amends. Mr. Payne makes no enemies needlessly, even at a time of such friction. And it would be unjust to impute nothing but adroitness to this Milwaukeean of marvelous executive ability. Henry C. Payne is a great man. He has a large heart and masterful brain."

THE NEW HEADQUARTERS OF THE N. Y. & N. J. TELEPHONE CO., BROOKLYN, N. Y.

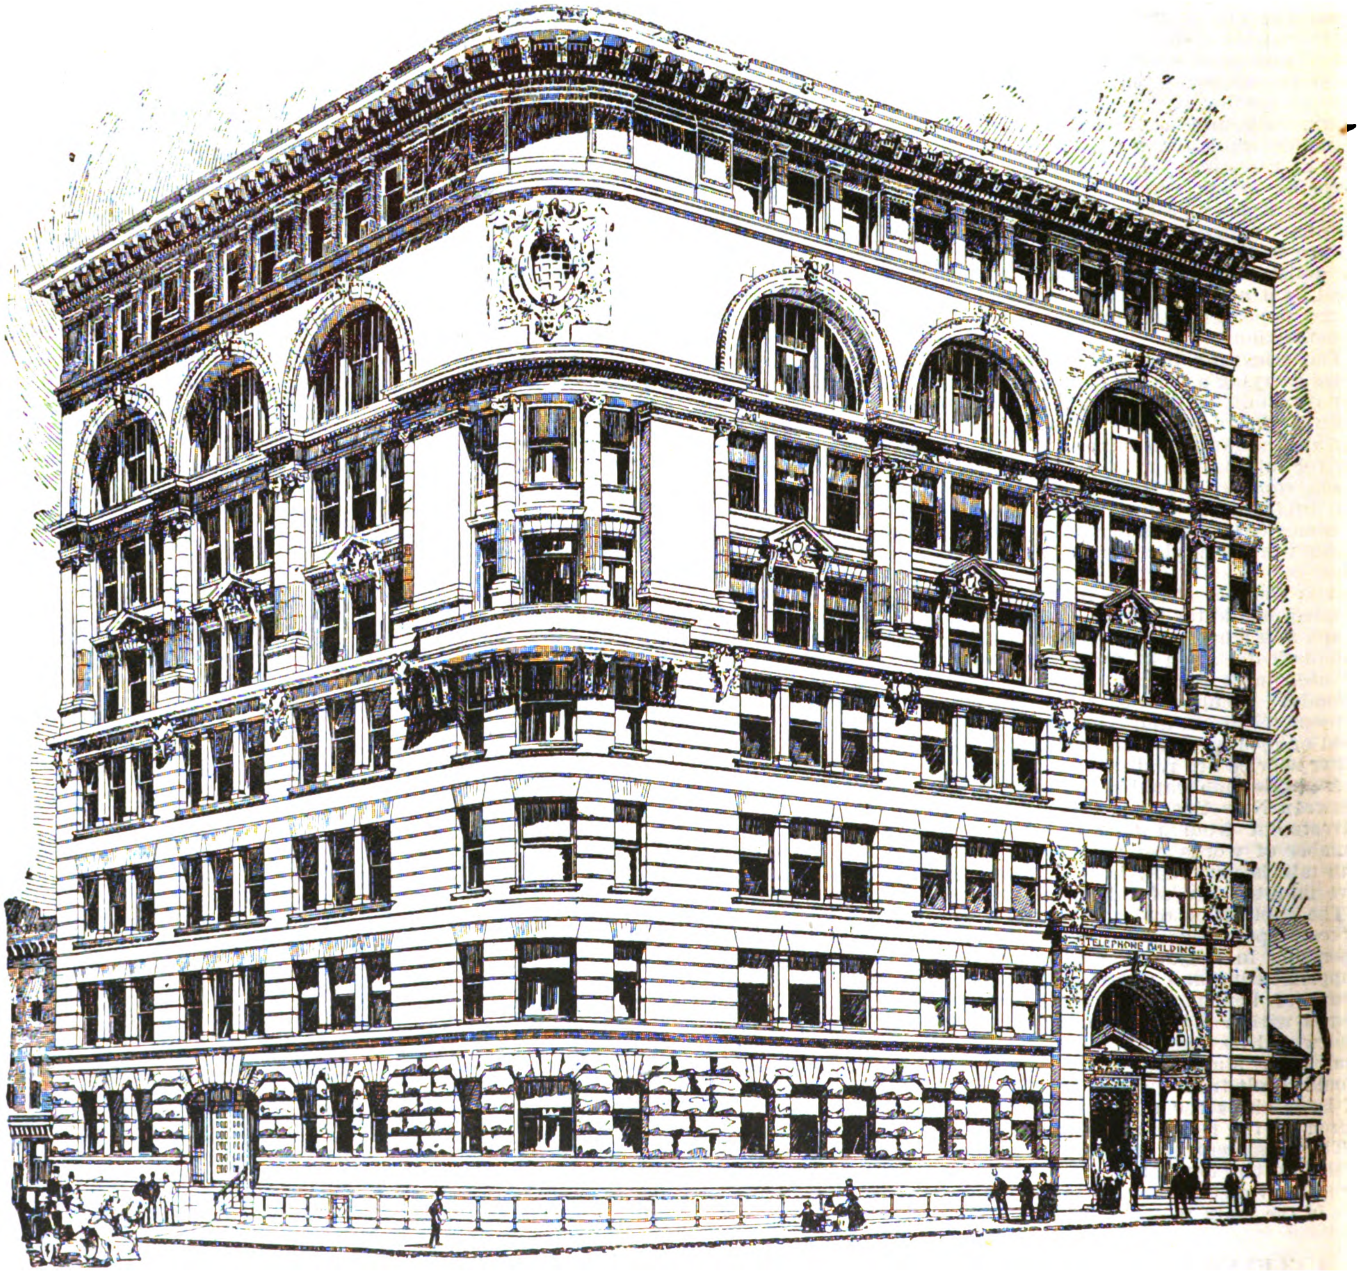
A SPLENDID addition to the notable buildings of Brooklyn will be that of the New York and New Jersey Telephone Building, which by next spring will be occupied by that company as the third step in its advancement from the beginning in 1883. The design of the structure is by R. L. Daus, the well-known Brooklyn architect, who has within a few years designed a number of buildings which are ornaments to the neighborhoods in which they stand.

The new telephone building will occupy a plot of ground on the northeasterly corner of Willoughby and Lawrence streets, with a frontage of 108 feet on Willoughby street and 100 feet on Lawrence street. It will consist of a basement and eight stories and be constructed by the most improved method of modern steel frame construction. The foundations are formed of heavy masses of concrete, some 4 or 5 feet thick and covering 50 to 60 superficial feet. On these concrete blocks are systems of heavy iron beams forming a grillage for the foundation of steel posts, extending through the entire height of the building. The floor construction is partly formed by hollow fireproof flat arches and partly of the Columbian fireproof construction. Dark blue Indiana limestone will form the lower two stories and pearl gray brick and terra cotta will be the principal material of the upper stories. The design is in the style of the Italian Renaissance and is one of great simplicity and dignity. This building will be one of the handsomest structures in Greater New York. It will be equipped with the most improved system of plumbing. Careful provisions have been made to supply the building with its own fireproof system. Two hydrants in the building are so situated that they can be used by the fire department to throw a stream 250 feet high, protecting both the building of the telephone company as well as adjoining buildings. Particular care has been bestowed upon the planning of the heating and ventilating of the building. One of the essential requirements of the operating room being its perfect freedom from dust, it was found necessary to bring the air from a shaft twenty-five feet above the roof to the basement, where it is screened through many layers of bolting cloth. The air will be supplied with the necessary degree of moisture, and by a system of fans distributed throughout the building. Exhaust ducts and powerful fans will expel the vitiated air and discharge it above the roof. The building will cost in the neighborhood of $300,000 and the telephone company paid about $55,000 for the land.

The New York and New Jersey Telephone Company was organized in 1883 and for five years occupied offices at 397 Fulton street, moving from there to its present quarters on Smith street in the summer of 1888. The charter of the company covers the territory of Long Island, Staten Island and the northern half of New Jersey. It had in 1883 2,339 subscribers from 30 exchanges, 1,656 of which were in Brooklyn, Williamsburg and Greenpoint. At the present time the company supplies service to over 16,000 subscribers from 86 exchanges. It has 21,642 miles of wire, 16,779 of which are underground and 4,863 aerial, in Brooklyn alone.

In 1884, a year before the subway laws were passed, it began the work of putting its wires underground. The last report of the subway commission, October 31, 1896, showed that the telephone company in Brooklyn had 11,655 miles laid underground. The mechanical operations of the company are in charge of J. C. Reilly, general superintendent, and F. W. Conn, assistant superintendent in charge of the Long Island construction.

The officers of the company are: President, Charles F. Cutler; vice-president and general manager, W. D. Sargent; secretary, Joel C. Clark; treasurer, Henry Sanger Snow; executive committee, Charles F. Cutler, Joseph P. Davis, W. D. Sargent, Joel C. Clark; directors, Charles F. Cutler, Alexander Cameron, Joseph P. Davis, Charles A. Nichols, Hugh Kinnard, William D. Sargent, David B. Powell, George H. Prentiss, Joel C. Clark, Felix Campbell, Edward J. Hall and Henry Sanger Snow.



The New Exchange Building of the New York and New Jersey Telephone and Telegraph Co., Brooklyn, N. Y.

THE BOUGHTON TELEPHOTOS, invented by Mr. C. V. Boughton, of Buffalo, and described some time ago exclusively in The Electrical Engineer, is being tested by the government with a view to its adoption by the U. S. Navy for men-of-war.

MECHANICAL

THE PRINCIPLES AND CONSTRUCTION OF WATER WHEELS.—II.

BY W. E. WINES.

THE three forms of water wheels most extensively used before the introduction of the turbine were the overshot, the undershot, and the breast wheel. The construction and operation of the overshot wheel is clearly shown in Fig. 2. Water from the head race flows into the buckets at the upper part and turns the wheel by virtue of its weight until discharged into the tail race, falling a total distance h. The general expression for the efficiency when applied to this wheel becomes

$$1 - \frac{1}{2}\frac{h_0}{h} - \frac{h_1}{h}$$

This shows that one-half of the entrance fall and the entire exit fall are lost; as it is possible to make both h and h_1 very small the theoretical efficiency of the overshot wheel may be very nearly unity, and its practical efficiency ranges from 70 to 90 per cent.

One of the greatest sources of loss is the spilling of the water from the buckets before they reach the bottom; but in times of drought when the water supply is scant the buckets become only partly filled, the spilling is reduced, and the efficiency is consequently increased. This is one of the greatest advantages of overshot wheels and in this particular they stand out in marked contrast with turbines, the efficiency of the latter falling off as the water supply is reduced.

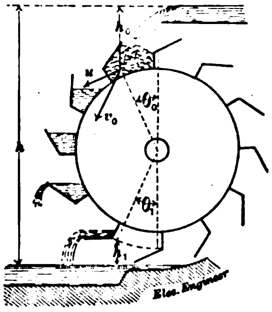


FIG. 2.—OVERSHOT WATER WHEEL.

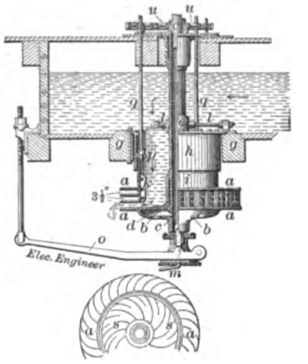

FIG. 4.—FOURNEYRON OUTWARD FLOW TURBINE.

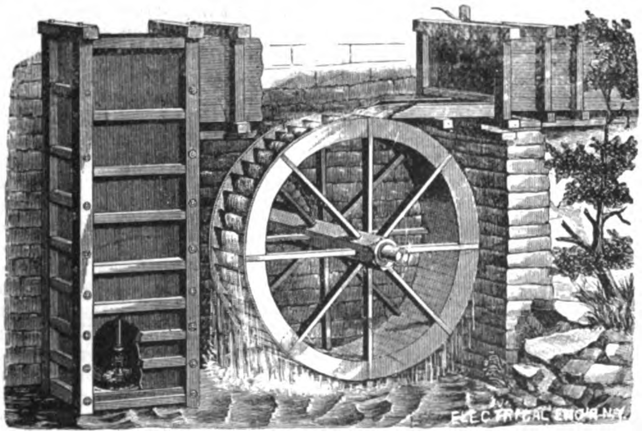
The diameter of an overshot wheel should be as nearly as possible equal to the head and when a rather high head is to be utilized this necessitates a wheel of enormous size and weight. The largest overshot wheel in use at present is located at Laxey, on the Isle of Man. It is 72 feet 6 inches diameter, develops about 150 horse power, and has an estimated efficiency of 65 per cent. A Pelton wheel of equal capacity working under the same conditions would be only about 6 feet in diameter and would have an efficiency of 85 per cent. The relative sizes of an overshot and turbine of equal power, working under the same head is shown in Fig. 3.

The undershot wheel has plane, radial vanes which dip into the water flowing through a more or less confined channel beneath it. The vanes being plane, only the impulse of the water is utilized and the theoretical efficiency is consequently only 50 per cent.; the actual efficiency varies from 20 to 40 per cent.

In the breast wheel the water acts partly by impulse and partly by weight. Water enters the wheel about on a level with the shaft, and is confined to the buckets by means of the curved breast which covers about one-fourth of the circumference. The efficiency of the breast wheel ranges from 50 to 80 per cent.



ELECTRICAL ENG'R N.Y.

FIG. 3.—COMPARATIVE SIZE OF OVERSHOT WATER WHEEL AND TURBINE.

The turbine, both in construction and operation, differs radically from the wheels already described. The wheel proper consists of curved vanes or buckets to which the water is led through suitable fixed guides in such a manner as to act upon the entire number of buckets at the same time. If the water flows from the axis outward the wheel is called an outward flow or, from its inventor, Fourneyron turbine; if the water flows from the outer circumference toward the axis it is termed an inward flow or Francis turbine; if the water flows through the wheel parallel to the axis it is known as a parallel flow or Jonval wheel.

The speed of the wheel is regulated by controlling the amount of water passing through it, the arrangement for effecting this being technically known as a gate. Gates are of two kinds, cylinder or register. A cylinder gate has the shape of a hollow cylinder or pipe which is placed between the guides and the wheel proper and may be moved parallel to the shaft, thus varying the cross section of the passages between the wheel and the guides. If the guides themselves are capable of a slight motion by which the size of the water passages between them may be varied the arrangement is termed a register gate. It is similar to an ordinary hot air register.

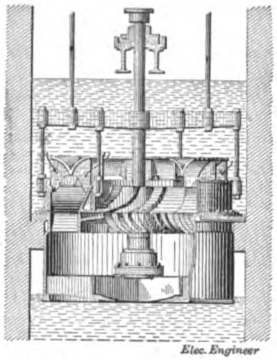


FIG. 5.—JONVAL OR PARALLEL FLOW TURBINE.

An outward flow turbine designed and built by Fourneyron is shown in Fig. 4. The upper view is half elevation and half vertical section; the lower view shows a horizontal section through the guides and buckets. The wheel proper a a has a dish-shaped bottom b b which is rigidly fastened to the vertical shaft c which passes through the sleeve e. Water enters as shown by the arrows and passes through the guides s and the buckets a (shown in the horizontal section), the direction of its motion while passing through the wheel being from the axis outward. The amount of water used is regulated by means of the cylinder gate i. Vertical rods q q are bolted to lugs p on the inside of the gate. The upper ends of these rods are threaded and are screwed into the gears u u; these gears are rotated by means of the pinion w and the gate is thus raised and lowered.

A type of Jonval or parallel flow turbine manufactured by R. D. Wood & Co., is shown in vertical section in Fig. 5. The water enters as indicated by the arrows and after passing through the guides enters the wheel proper, its course being parallel to the axis of the wheel. The guides and buckets are very clearly shown, as is also the cylinder gate, which is raised and lowered by the two small vertical rods parallel to the shaft.

The component parts—wheel, guides and gate—of an inward and downward flow turbine, built by Alcott & Son, are shown in Fig. 6. When the wheel is set up ready for use it is placed inside the gate. The gate is capable of rotation about a vertical axis, this motion serving to vary the amount of water supplied to the wheel and hence regulating the speed. In order to supply water to all the buckets at the same time it is placed in a flume and completely submerged, the water being supplied through a penstock.

VOL. XXIII. NEW YORK, MAY 19, 1897. No. 472.

SCOPE OF THE BERLINER PATENT DECISION.

THE Supreme Court has rendered its judgment in the suit of the Government against the Bell Company, for the annulment of the Berliner patent, and its dictum, given in these columns last week, is that no fraud was proved against Berliner in his proceedings in the Patent Office, that therefore, the patent must be considered as issued in due form and hence rightfully in the possession of the inventor and his assignees. As to all other points brought forward by the government the Supreme Court flatly refused to consider them, following a time-honored custom which has already caused much impatient grumbling. The nature of the decision has very naturally caused widespread satisfaction and dissatisfaction, but far from causing dismay in the camp of those opposed to the Bell Company, it seems rather to have brought joy to their hearts. As a matter of fact, the Supreme Court decision relieves the Bell Company of the onus of fraud, but also now places upon it the onus of proving its right to the exclusive use of the Berliner transmitter by an infringement suit brought in the regular way. The decision leaves open all the usual defences against the validity of the patent, many of which have been brought to light in the discussions of this patent. For instance, it is held questionable whether the Berliner patent granted in 1891 is a valid patent in view of the fact that in 1880 Berliner obtained a patent on identically the same apparatus but with different claims. In the cultivator case (Miller vs. Eagle Manufacturing Company), the Supreme Court decided, under similar circumstances, that the second patent was invalid. In the opinion of one of the foremost patent lawyers in the country, it may be doubted whether the courts would find that the 1891 Berliner patent is for the same invention as that described in Berliner's original application filed in June, 1877. At the start the application described a transmitter having platinum electrodes—an evidently inoperative device for a variable contact transmitter—while by a series of amendments it was made to describe an instrument having carbon electrodes and operating on the microphone principle. It is one of the fundamentals of the patent law that variations of this kind will not be tolerated, especially when their effect is to include meritorious inventions made between the filing of the original application and the grant of the patent. The Berliner patent, No. 233,969, of November 2, 1880, above referred to, was a division of the original application of June, 1877. This patent describes and illustrates the same devices as the Berliner patent of 1891, just adjudicated by the Supreme Court, but the claims cover the use of the apparatus as a receiver. This 1880 patent expires this year and after November 2 the anomalous condition of affairs will exist that the use of a Berliner microphone transmitter applied to the ear will be lawful, while if applied to the mouth it will be an infringement. Of course the Berliner microphone is absolutely valueless as a receiver and no one would think of using it as such.

So far as we can gather, it is also open to doubt whether the courts would sustain the Berliner patent based on the useless transmitter having platinum electrodes as covering the subsequently invented and highly meritorious transmitter provided with carbon electrodes. It will be remembered that in the litigation on the Sawyer and Man patent, the claim was for a carbon for incandescent electric lamps made from fibrous vegetable material, and on this claim it was sought to enjoin the manufacture of the Edison lamp having a bamboo carbon. Sawyer and Man, in their patent, referred to paper as an illustration of their fibrous vegetable material from which the carbon could be made. The Supreme Court decided (following Mr. Justice Bradley, who decided the case below) that because inventors had discovered the utility of one material, they could not cover a subsequently discovered and different material, simply because their material was capable of being described in language which embraced the later material. The reason which led the Supreme Court to apply this principle to the Sawyer and Man patent was that paper carbon had a very small degree of utility, while bamboo carbon was highly useful. The same reason may be held to be applicable to the Berliner patent, and the courts might very possibly say that because Berliner's useless platinum electrodes are capable of being described in language broad enough to include the subsequently invented and highly useful carbon electrodes, is no reason for interpreting Berliner's claim to cover anything more than a telephone with electrodes of platinum or some equivalent material, which carbon certainly is not.

Undoubtedly many other defences against the Berliner patent will be brought forward by the opposing telephone interests. Among others, it has been suggested that foreign patents were granted to Berliner, which have expired and carry with them the United States patent, but we have not as yet seen any definite proof of the statement.

RECENT X-RAY PROGRESS.

FAR from falling off, the interest in the study of the results obtained in X-ray work is constantly increasing. Indeed scarcely a week passes but some improvement in the methods and apparatus employed for the production of X-rays is brought forward, or the list of successful applications broadened. The Electrical Engineer has tried to keep pace with this progress, and its pages have from week to week borne testimony to the richness of the soil first broken by Prof. Röntgen. The most noteworthy achievement in X-ray photography which has yet come under our notice is the recent work of Dr. W. J. Morton, who has succeeded in obtaining a full-size picture of the human skeleton on a single photographic film. The reduced reproduction of this film, printed elsewhere in this issue, gives but a faint idea of the actual photograph.

As regards the apparatus for the production of the rays probably the most work has been done with a view to the securing of permanency and reliability in the X-ray tube itself, and it may be fairly claimed that at the present time the most improved tubes cause the X-ray worker practically none of the inconveniences that were observable with the original tubes employed. It is now admitted that an X-ray outfit has come to be indispensable to the surgeon. But with its benefits has come also the necessity for greater precautions than have heretofore been observed in the use of Röntgen ray apparatus. The cause and nature of the X-ray burn, so called, has been the subject of special investigation. But here also experience has clearly defined the danger limits. Mr. Tesla's investigations in this direction, noted in our last issue, have called forth an interesting communication from Dr. F. S. Kolle, who has done much intelligent work in Röntgent ray photography, and who shows that X-ray burns do not differ from the usual irritations of the skin, and that they readily yield to proper treatment. We have also received a communication from a high electrical authority, commenting on Mr. Tesla's work, and pointing out that Mr. Tesla in his recent contribution to this subject has taken an entirely different stand from that which he seemed to have established some time ago. Thus he formerly claimed that the injurious effects pertaining to the use of Crookes tubes were due to electrostatic effects, and not to the X-rays, or were due to the production of ozone by electrical discharges around the tubes, and that the X-rays themselves were not to be considered as the really injurious agency. According to the same authority, Mr. Tesla has hardly put forward enough experimental evidence to make it essential to abandon the use of bulbs containing platinum, and more particularly as he does not show how a properly constructed Lenard tube can be made. It is not easy to join a piece of aluminum to a piece of glass in such a way that the joint will be maintained under the highest vacuum, and under the changes of temperature. The expense of such structures would also be far greater than that of the ordinary platinum tube, and besides it is not believed that platinum is by any means an essential metal to be used as a target, but that any heavy metal, such as tungsten, uranium, molybdenum or iridium will answer.

Viewed from a broad standpoint we believe that we shall hear very little about X-ray burns in the future, for X-ray apparatus has been now so well developed and the time required for exposure to obtain good pictures has been so reduced that the effects heretofore noted are not produced. The surgeon who operates with an outfit requiring more than a few minutes exposure, except in very extreme cases, would be considered as incompetent as one who would attempt to operate with a dull knife, or without the usual antiseptic precautions indicated by modern medicine.

THE THIRD RAIL EXPERIMENTS AT HARTFORD.

FORCED by the competition of parallel trolley lines, the New York, New Haven and Hartford Railroad some time ago took the bull by the horns and introduced electric service on a part of its lines, the first experiment being carried out on the Nantasket Beach branch of its system. This section was the first steam road of this kind equipped with the third rail, and, encouraged by the results, the same company has now equipped another section of its road between New Haven and Berlin, Conn. The experiments upon this road made last week show that the speeds obtainable were as high as, if not higher, than those which could be reached by means of steam locomotives. All this, of course, has created quite a furor among the readers of the daily newspapers, but to those who have followed the course of events in electric railroading for the last few years this achievement will cause no surprise. The event is, nevertheless, of considerable importance as foreshadowing the possible, and, indeed probable, future change in the method of operation of present steam roads. If merely for the sake of argument, we acquiesce in the opinion of steam railway managers, that through business will for an indefinite period continue to be performed by steam locomotives, we nevertheless believe that enough has already been demonstrated to show that local traffic is gradually but surely drifting in the direction of electric traction on present steam roads. The paralleling of trolley roads has already cut very seriously into the receipts of steam roads from this class of traffic, and if the business is to be held by the steam roads they must furnish equal accommodations with the present trolley road—in other words they must be converted into trolley roads. The ready manner in which this change can be carried out by means of the third rail is self-evident, and we expect to see a great deal of this class of work done in the near future. Looking further, however, it must be apparent that a section or division of a road electrically equipped for local traffic must by the sheer force of circumstances and economy in operation be finally forced to abandon the steam locomotive entirely. With the evidence before them that the highest speeds are attainable by electricity, and that it possesses other advantages and benefits, we venture to say that the through electric trunk line is not so far off as steam road managers may honestly believe it to be. We will go even so far as to venture the assertion that steam roads will in the course of time actually be forced to adopt electricity, for the reason that the first road so equipped will attract towards itself such a volume of patronage that competing lines will be forced to offer equal advantages if they would hope to maintain their business. From whatever standpoint we view the subject, the conclusion forces itself upon us that electricity must finally become the motive power of all railways. Far from sharing the opinion of the present steam railroad managers, that electricity will entail additional operating expenses, we believe the contrary to be true. But even if such were the case, the difference between the two cannot be so great as to cause its entire rejection. The problem here involved, it must be admitted, is not a small one, indeed it is one of the greatest possible moment to the national economy, but it is rapidly nearing its solution, and the outcome will be watched with more than general interest by the railways and travelers alike.

MUNICIPAL GAS A SAD FAILURE.

A SPECIAL committee of the Pennsylvania State Senate has just submitted its report on the working of the departments of the City of Philadelphia. The report embodies many interesting figures, the only inference from which is that there is scarcely a single branch of public service that would not be better attended to and less expensive to the city in private hands. The data on the municipal gas works will serve, however, to point the moral and adorn the tale. The gas works of the city are valued by the Mayor at $30,000,000, and it is said that $25,000,000 has been offered for them. The report says they could be easily duplicated for half the smaller sum, so that the remainder must represent what we will call the franchise; and the committee says very lugubriously: "It would seem, therefore, proper that the City of Philadelphia should realize upon this franchise while it yet exists, and before private gas companies, gasoline lamp companies and electric lighting companies occupy so much of the field as to render the franchise of but little value, or else invest the money necessary to render its work efficient and profitable; that it is better to lease or sell the works while they are yet valuable than to wait until their main value is destroyed by competition, fostered and maintained by inadequate management."

One of the witnesses estimated the loss to the city every year from this big investment at not less than about $700,000 per annum, and the report says: "The cost of manufacturing gas at the city's works is undoubtedly excessive, and the amount received by the city from the sale of the residuals much less than it ought to be. The analysis of the accounts published in the reports of the bureau, as made by one of the witnesses, whose technical training and large experience in the conduct of successful and profitable gas companies is universally recognized among those familiar with the business, shows that the cost for labor in the city's works is about three times what it should be, the produce being only about 10,000 cubic feet per day per man instead of 30,000 feet, which is the result in properly organized works. The excess of cost to the city for this item alone is about $225,000 per year." It is no wonder that the city does less than half its own lighting, and buys more than one-half of its gas supply from a local company which sells it gas at 37 cents per 1,000 cubic feet.

Philadelphia has been discussing the advisability of having its own electric light plant! Surely such figures as these should stand in the way and prevent further waste of public money. The report intimates that things would go better if the management were entirely divorced from politics. That we can well believe. It is often intimated that politics also have a great deal to do with lighting contracts to private companies. That is doubtless true. But the politics are necessarily minimized after the contract is let, whereas, from all we have ever been able to find out, the politics of a municipal plant come into full play when it gets going, and is one more "piece of pork." That is the mischief.

TROLLEY ROAD REWARDS OF MERIT.

WASHINGTON, D. C., sends the dismal and astounding story of the discharge of an excellent car conductor, on the complaint of senile Senator Hoar, because he ventured to treat that aged statesman as an old man in need of help when getting into the car. Of a truth, the polite conductor often does not know what to do, especially when his amiability is rewarded by his prompt dismissal. It is not always so, and the steady advance of street railway companies in the material recognition of the good behavior of their employés, is bearing excellent fruit. Out in San Francisco, as on the New York Central, the men of the San Mateo trolley road are decorated with medals and good conduct stripes, and get money rewards withal. E. H. Bohle, the winner of the first prize as a conductor, getting a badge and $12.50, never had an "oversleep" or a complaint from passengers. Iver Jones, first among the motormen, gets the badge and $40. He has never had an accident in five years, and therefore, with a humor that is distinctly Bret Harteian, is always placed in charge of the funeral car when burial parties are taken out. Since the road introduced its merit system, complaints and accidents have greatly fallen off. But the road is lucky in not carrying cranky Senators as passengers.

CHICAGO EDISON EARNINGS.

THE report of the Chicago Edison Company, published on another page, makes a good showing, one in fact that might be considered remarkable in view of the severe depression undergone for some time past by the metropolis of the West. There is a gain of 9 per cent. in the gross earnings, and the increase in business is the equivalent of 34,408 lamps of 16 candle-power. The net profit is also larger in spite of the larger amount necessary for the bonds and for the dividends. Two things are evident; first, that the company has been very prudently and skillfully managed, and next, that the company has but barely begun to enjoy the returns possible from its admirable equipment, described in these pages not long since. The company has put itself in the best possible shape to benefit by the returning conditions of prosperity, which, evident already in other cities, will be sure to show themselves in a marked degree before long in buoyant Chicago. Such figures as these, coupled with those of New York, Boston, Brooklyn and Philadelphia, go to demonstrate very strikingly also the staying power and great permanent earning capacity of the modern central station when operated not merely to supply one form of light, but to serve as a reservoir of current for all manner of uses.

ELECTRIC TRANSPORTATION

THE COLUMBIA ELECTRIC MOTOR CARRIAGE OF THE POPE MANUFACTURING CO.

At the invitation of the Pope Manufacturing Company, of Hartford, Conn., we were given an opportunity to witness an exhibition of, and to thoroughly inspect, the new electric motor carriage designed by that company, a view of which is given in the accompanying engraving, Fig. 1.

The present vehicle, we may premise, is not by any means a recent or experimental creation. As a matter of fact, the Pope Company began experimenting in the line of developing a horseless carriage nearly three years ago. Shortly afterwards, a fully equipped factory was allotted for this work, and the Motor Carriage Department of the Pope Manufacturing Company was formally organized. Their investigations and experiments were by no means confined to the field of electricity, but several types of automobile vehicles were built, with the idea of testing every device or mechanism available, then known to the art, besides applying to their experiments the knowledge and investigations of their own experts and inventors.

The motor carriage driven by a gasoline engine, which crude and experimental as it is, and unsusceptible as it is of operation in unmechanical hands, is still the most common type. However satisfactory or otherwise the operation of the gasoline carriage may be in the hands of experts, it is considered as yet neither a practical nor safe device to put in the hands of an inexperienced operator. This, coupled with its ready liability to derangement and its very objectionable æsthetic features, led the Pope Company, while energetically pursuing their investigations in that line, to suspend any attempt to market a vehicle of this type until these very serious objections have been overcome. That the advent of a popularly operative gasoline or other similar motor carriage is near at hand, they have every reason to doubt. At present its very objectionable unæsthetic features of noise, smell, smoke, vibration and heat are especially noticeable in the crowded streets of a city, and were a matter of comment on the part of all recent visitors to the celebrated Parisian Champs Elysees.

The electric carriage, with its almost noiseless action and perfect ease of control, certainly comes very near to being the ideal horseless carriage. At all events, it stands to-day the only carriage which the company's experiments indicate to be available for popular use.

The first experimental electric carriage built by the company was put in commission over a year ago, and since that time has been in constant use, having made a mileage of about 3,500 in and around the City of Hartford. It has been driven over all kinds and conditions of roads and through deep mud and snow. It was given into the hands of people without the slightest mechanical training or previous experience. Even the most unskilled, after a few words of explanation, were able to control and steer the carriage with perfect safety and ease. During this long period of use and even abuse, it never met with an accident serious enough to be taken home by any other power than its own.

On this experimental vehicle are modeled the present carriages. They embody the well tested scheme of construction and equipment of their forerunner with such improvements as have been suggested by its use. They are designed for two occupants, and have the general appearance of a Stanhope phaeton.

The power is supplied by chloride storage batteries of the type best adapted to meet the required conditions of greatest efficiency with least weight and consistent with reasonable life. These can be charged from any 110 volt direct current circuit, such as is used for lighting in most factories, private plants and most towns of any considerable size.

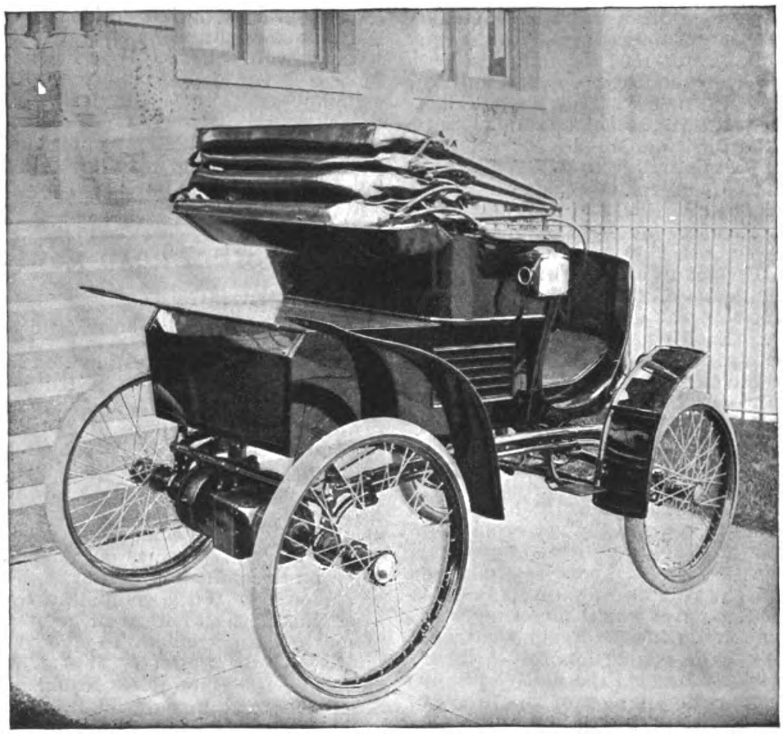

Fig. 1.—The Columbia Electric Motor Carriage, Built by The Pope Manufacturing Co., Hartford, Conn.

The normal power of the carriage, or that required to drive it at a speed of 12½ miles per hour on a level asphalt pavement is 18 amperes at approximately 80 volts. This is an output of the batteries of 1.93 horse-power. The efficiency of the motor is 80 per cent., and assuming that the loss in the gearing of the carriage is 10 per cent., makes the total efficiency of the motive mechanism 70 per cent. This means that with 1.93 horse-power going in from the batteries 1.35 horse-power, practically 1⅜ horse-power, is being exerted at the rim of the wheel.

The motors are built for a normal load of 2 horse-power. Their specifications called, however, for them to stand an overload of 100 per cent., or 4 horse-power for one-half hour without injurious heating. The capacity of the batteries is 70 ampere hours at a discharge rate of 25 amperes. This means that 25 amperes discharge be maintained for 2.8 hours, which on ordinary roads could be expected to propel the carriage between 30 and 35 miles, according to the number of stops made and the conditions of the grading of the road. The actual weight of the batteries is 350 pounds. There are 44 cells, which enables them to be directly coupled to the 110 volt continuous current circuit for charging purposes.

The weight of the finished carriage has not been obtained, but from the weight of the rough carriages it is probable that this weight will be 1,900 pounds. The weight of the motor is 129 pounds. The motors are of Eddy make.

As the carriage is intended to be placed in the hands of the general public, special provisions have been made for preventing damage to batteries from careless handling, and also to prevent waste of current; for this purpose an automobile cut-out is provided that cuts off the current on the completion of the charge.

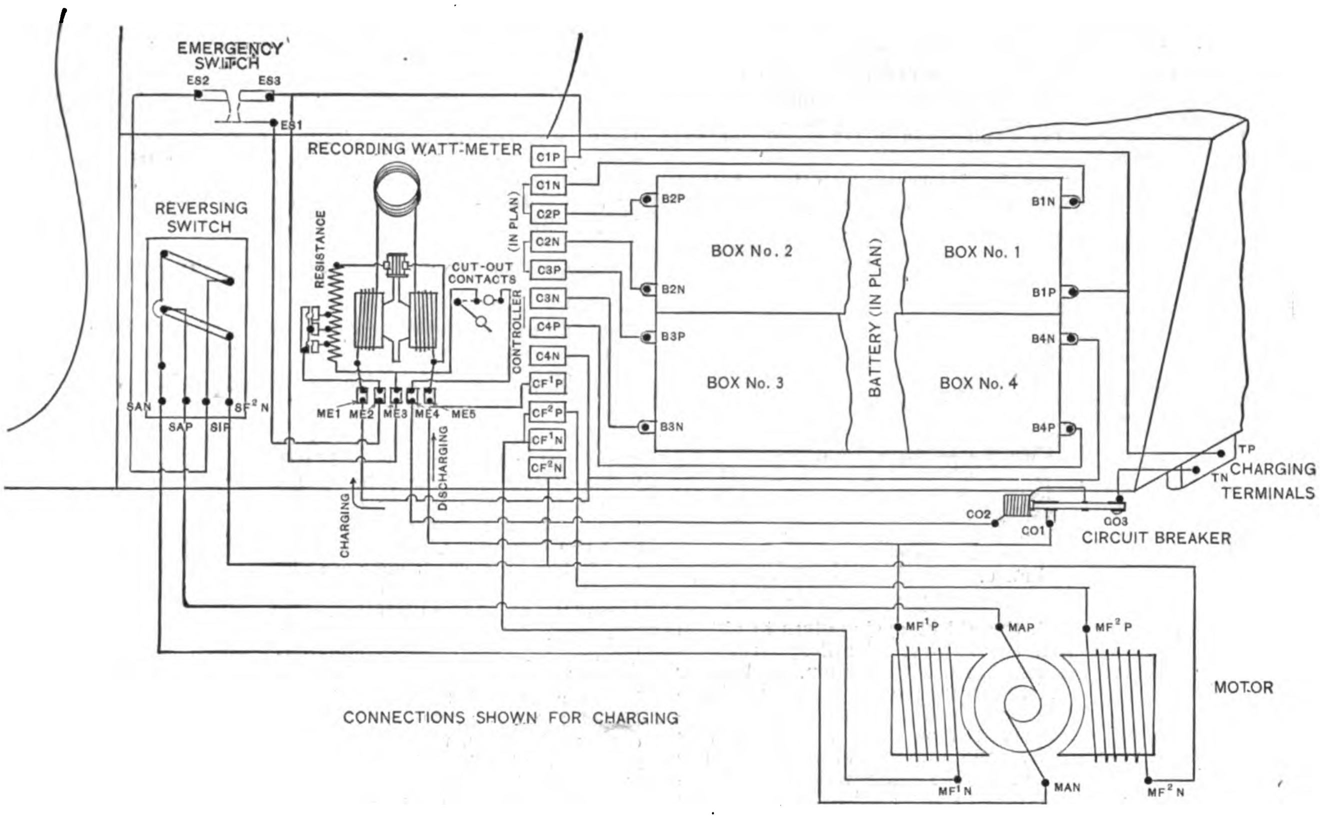

Fig. 2.—Wiring Diagram of Columbia Electric Motor Carriage.

On the diagram, Fig. 2, the cut-out is shown at C. O. 2, C. O. 1 and C. O. 3. The recording watt meter which actuates this cut-out is shown under the title "Recording Watt Meter," and its object is to show at all times the condition of charge of the cells.

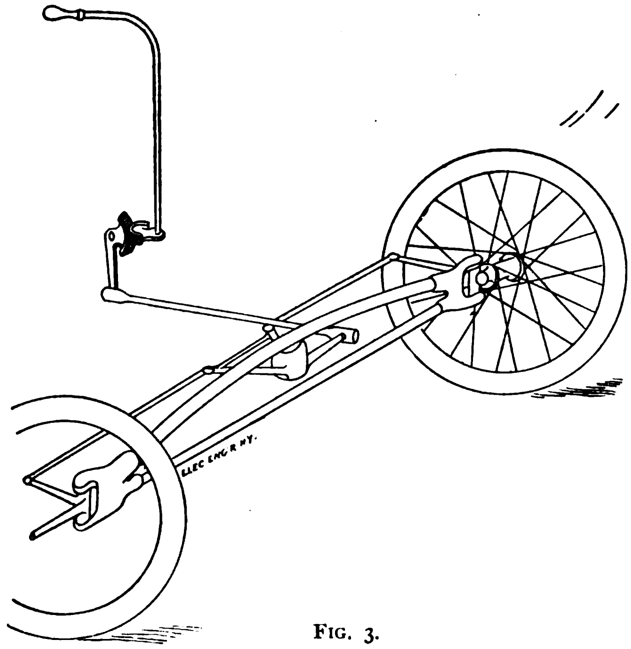

Fig. 3.

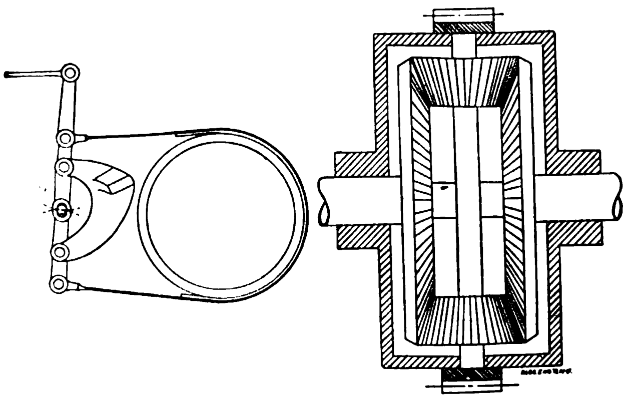
The connections are so made between these two devices that when the charging current enters the carriage the wattmeter runs backward at a speed lower than what would be the case with the same current during discharging. This provides for the loss in efficiency in the battery. Thus, when the indicator finger on the motor has returned to the "full' position on the dial it is plain that slightly more current has gone into the battery than was taken out. Two small contacts after the manner of the ordinary electric alarm clock are provided at the "full" position so that when the finger reaches this point the circuit is completed through the electro-magnet of the cut-out which actuates and permits of the main switch of the carriage being thrown out. Thus by simply inserting the charging plug in the carriage and closing the main switch, no attention whatever is required until it is desired to next use the carriage. The recording watt meter is of a special type made especially by the General Electric Company.



Figs. 4 and 5.

The reversing switch, shown under the title "Reversing Switch," is not put in the controller on Columbia carriages for the reason that in some cases it is possible for an excited person during an emergency to quickly draw the controller from full speed ahead to backing. This plainly would be liable to cause serious results. In its stead a special reversing switch is put in which is operated by the heel and which makes it practically impossible for an unthinking or careless person to reverse the current in the motor when the carriage is going at high speed ahead.

The emergency switch is a small plug conveniently near the seat, which an operator can always pull out in case of any accident to the motor which would prevent its being stopped.

All battery connections, and, for that matter, all connections throughout the carriages which have to be manipulated in any way are made of two different size holes, all of the positive holes being the larger. Thus no negative plug can be inserted in a positive hole or any positive plug inserted in a negative hole. This is another feature of "fool-proofness" which makes it impossible to make any wrong connections.

The expense of charging where the current is taken from the city mains is estimated not to exceed 50 cents. If the carriage owner possesses a private electric plant, the cost is much less, and under favorable conditions would not exceed ½ cent per mile.

In this connection it may be interesting to record that before venturing to produce electric carriages for sales purposes, pains were taken with the aid of cyclometers to obtain the best data possible upon the subject of mileage requirements of private citizens, surgeons, expressmen, and other constant users of vehicles. Some idea of the periodical expense of running a carriage whose mileage cost of operation is known, may be derived from the fact that this investigation indicated an average mileage of about 18 per day, and with one exception, a maximum mileage not exceeding 25. That exception was in the case of a veterinary surgeon who had a large country practice.

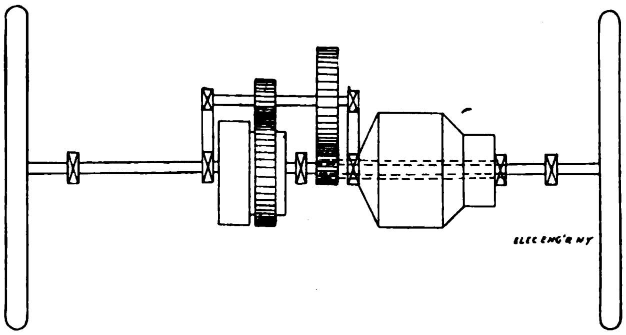


FIG. 6.

The Pope carriages are designed for a maximum speed of between 14 and 15 miles per hour on good roads. There are also three lesser speeds, one of twelve, one of six, and one of three miles per hour. All these speeds can be obtained backwards by a very simple manipulation, and the carriage is steered with the greatest ease and a minimum of muscular effort by means of the steering apparatus shown in detail in Fig. 3. There is a powerful foot band brake, Fig. 4, which can be quickly and effectively applied, and a warning signal is provided of distinctive and powerful, though agreeable tone.

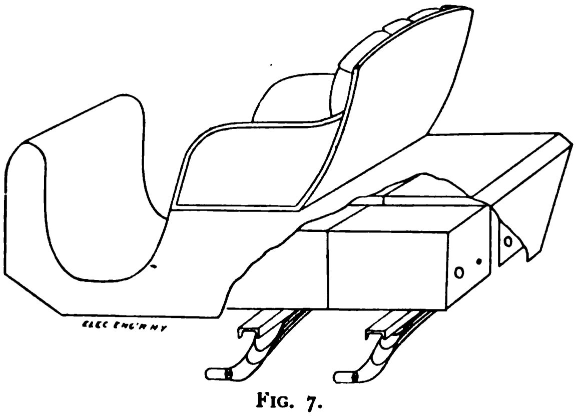

FIG. 7.

The engraving, Fig. 6, shows a plan of the rear axle illustrating the relative arrangement of the motor and driving gear. Fig. 5 shows the special balance gear, and Fig. 7 illustrates the method of supporting the batteries on springs.

When leaving the carriage standing in the street or elsewhere, one can, by taking out the emergency plug, which is of a size to conveniently go into the waist-coat pocket, make it impossible for any one, not possessing a similar plug, to use the carriage. The connection is broken by removing this plug, so that the carriage cannot again be moved by its own power until the plug is replaced.

The wheels are fitted with ball bearings, which are also used elsewhere throughout the carriage wherever of possible advantage. The tires are three-inch pneumatic, of especially durable construction, and are practically non-puncturable under any probable conditions. The construction, material, and dimensions of these tires, which are the well-known Hartford single tubes, lend materially to the care of running and relieve the structure of many shocks which would otherwise tend to reduce its life.

The frame is of special steel tubing, manufactured and tested for this particular purpose. All details of construction are worked out to provide the greatest strength with the least sacrifices of lightness and elegance. Such parts of the running gear as would be exposed under the carriage are covered with neat housings to prevent the entrance of mud or dust. In short, the carriages have been built on strictly bicycle lines.

SENATOR HOAR AND THE POLITE CONDUCTOR.

Senator George F. Hoar always was a peculiar man, and advancing age emphasizes rather than mitigates his aberrancies from normality. Our attention has just been called to a remarkable episode in which he took part last December. It deserves a brief recital as casting considerable light on the veteran statesman's character. It seems that one day after the Senator had completed his exhausting labors at the capitol, and was on his way home, he signaled to a street car that was passing the corner of Pennsylvania avenue and Sixth street. As it stopped for him he endeavored to step aboard, and the conductor, noticing that the would-be passenger was an obviously decrepit old man with snowy hair and obliged to lean heavily on a stout cane, grasped his arm and endeavored to assist him to the platform. Instantly there was an explosion of anger. The Senator resented the silent insinuation against his agility. He tried to strike the conductor with his cane, and when prevented by the other passengers from doing this began a violent tirade against the man's officiousness that lasted for ten minutes. Next day Senator Hoar visited the company's office, reported the conductor's name and number, and demanded his discharge. The man declared that he had simply tried to give assistance to a man who needed it, but he was suspended for thirty days. At the end of that period he was permanently discharged because he had been overheard commenting bitterly on the Senator's action. Since then he has been unable to get employment on any line in Washington, though he is a man of excellent reputation and long experience. All the people who saw the encounter with the Senator say that the conductor's behavior was irreproachable from the beginning to the end of the exciting episode. Among these witnesses is the Rev. Dr. Powers, pastor of the Vermont Avenue Christian Church.—New York "Times."

THE THIRD RAIL EQUIPMENT OF THE N. Y., N. H. & H. RAILROAD BETWEEN NEW BRITAIN AND HARTFORD, CONN.

THE New York, New Haven and Hartford Railway directorate has made another advance in the application of electricity in the operation of its road, in the electrical equipment of its line running from Berlin to New Britain on the New Haven system, Hartford Division, and from New Britain to Hartford, on the New England system, Springfield Division. The first electric car was officially run over the electrically equipped track on the 11th inst. by Col. N. H. Heft, the chief of the electrical department of the N. Y., N. H & H. R. R., in the presence of the president, C. P. Clark, Vice-Presidents Hall and Mellen; the directors and other prominent officials of the New Haven and New England systems.

This section is the longest section of any railroad in the world, hitherto exclusively operated by steam locomotives, to be equipped for electric traction. The total distance is 12.3 miles, divided in two parts. The first running from the power house at Berlin, the second extending from New Britain to Hartford. The road from Berlin to New Britain is single track; from New Britain to Hartford double track, the east-bound track only being devoted to electric service. In the operation of this road the electric trains will run from Berlin to New Britain and back. The trains from New Britain to Hartford and back run as a separate service, the change of cars being made at New Britain.

This important system differs in its electrical equipment from that at Nantasket in that the trolley system of contact is not used. That adopted is the third rail system, the conductor or third rail being laid along the center of the track between the running rails.

The power station of the New York, New Haven and Hartford Railroad is No. 3, that at Nantasket being No. 1, No. 2 being the power station at Stamford, Conn., from which the local trolley line is supplied with current. Power station No. 3 is a brick and stone building, two stories high, divided by a central wall into two parts—boiler room and engine room. In its present condition it forms only about half of what the station will ultimately be. The north side is closed in by boards. At what will be the center of the front wall of the completed building is a bay in which the switchboard is erected. The present length of the building is 113 feet 3 inches, its depth exclusive of the bay, 102 feet 5 inches, and height to ridge pole 65 feet. It is divided by a 26-inch brick wall into two parts, the front part facing the railroad is the engine room. The rear contains the boiler equipment.

The boilers are ten in number, each of 300 horse power. They are tubular boilers built by E. Kendall & Sons, Cambridgeport, Mass., and are set in two batteries of five each. In the construction of the boiler front a new method, devised by Col. N. H. Heft, chief of the electrical department of the consolidated road, who has carried out the entire electrical installation, is followed. The entire boiler front is capable of being taken down without disturbing the rest of the boiler setting, the front being bolted to a plate attached to the dividing wall instead of to the wall itself.

There are two feed water pumps, either pump being capable of supplying water to both batteries at once. The piping from the boilers is in duplicate and will be covered with non-conductive covering. The flues enter a brick stack 125 feet high, located immediately in the rear of the center of the present building. The coal used is known as locomotive sparks, the burning of which has given considerable satisfaction at the Stamford station. The coal is taken directly from the tracks in the rear of the station and is emptied into a large bin running along the back of the building.

The engine section of the building is divided into two stories, the upper one of which will contain the engines and dynamos. It is lighted by windows both in front and at the side, and is very high, spacious and well ventilated. One engine is in place, the foundations are in for another, and a third will be added as soon as demand warrants. The projected extension of the building will hold three more, and as each engine will have a capacity of 1,200 horse power the total capacity of the station when completed will be 7,200 horse power nominal, which can readily be raised to 12,000 horse power. The engine at present in position is a Greene-Corliss improved cross-

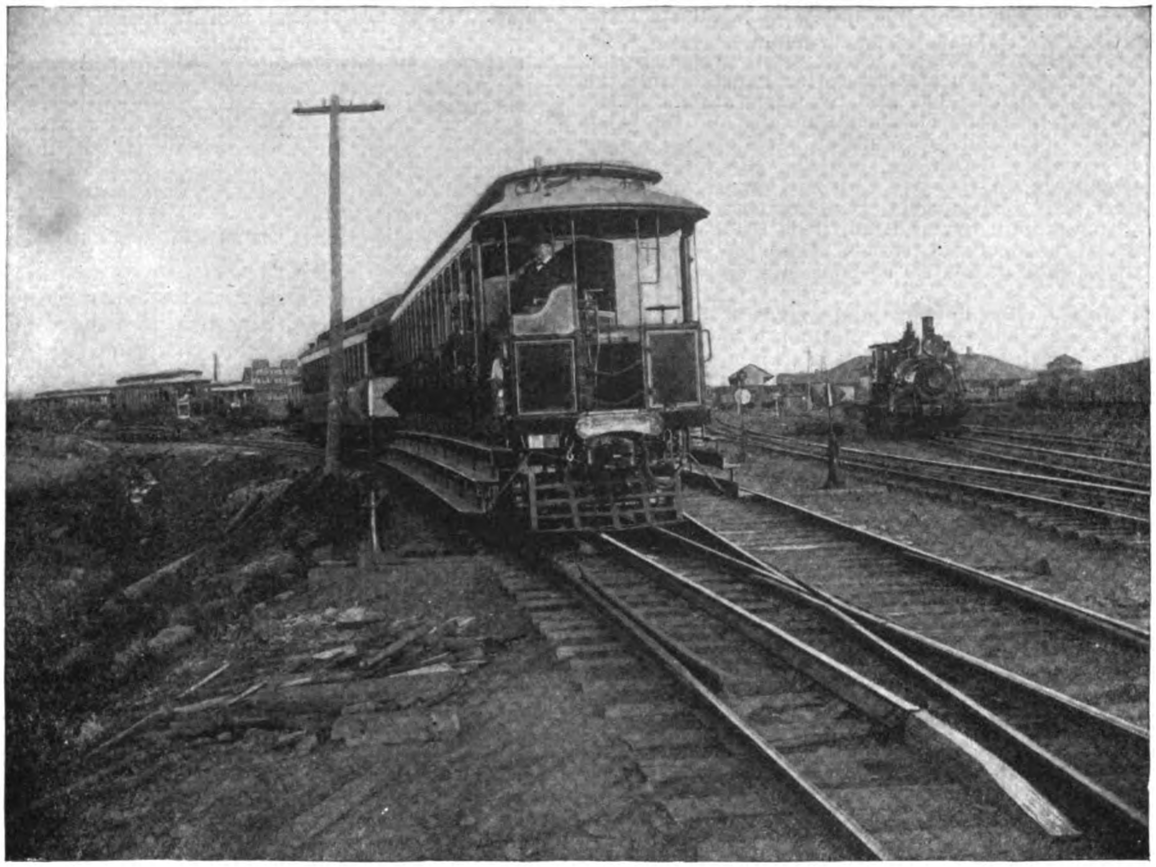

FIG. 1.—TRAIN, ONE MOTOR CAR AND ONE PASSENGER COACH, N. Y., N. H. & H. R. R.

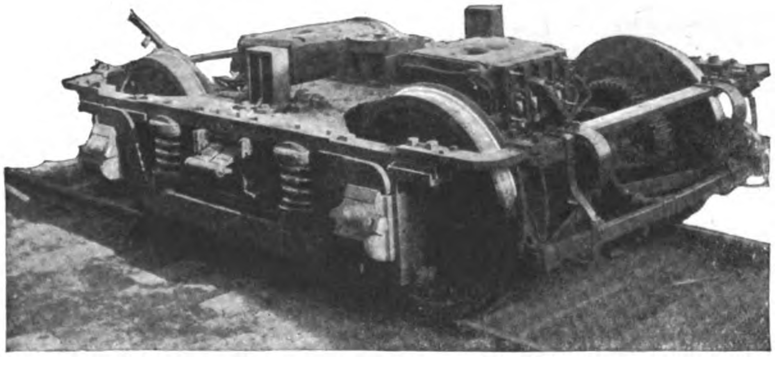

FIG. 2.—TRUCK OF MOTOR CAR WITH TWO G. E. 2,000 MOTORS.

compound, condensing, built by the Providence Steam Engine Company. It is rated at 1,200 horse power nominal, with dimensions 28 x 48 x 4 feet stroke, running at 100 revolutions per minute.

To the engines is directly connected a General Electric Company standard 10-pole 850-kilowatt generator of the ironclad type, with the method of construction of which our readers are familiar. The dynamos are over compounded and furnish current at 600 volts, no load, and 650 volts full load. The switchboard in the bay is of the G. E. standard panel type, built up of seven panels, four of which are at present blank. Of the three equipped, two are generating panels, while the third is a totalizing panel. The first two carry automatic circuit breakers with magnetic blow-out, ammeter and the usual generator panel equipment, the totalizing panel carries a form G Thomson recording wattmeter, showing the total output from the generators. A traveler with two cranes, one of 35 tons, the other of 5 tons capacity, runs the length of the engine room. It was built by the Berlin Iron Bridge Company, which furnished the steel roof trusses. From the switchboard run four cables, each of 850,000 circular mils cross-section to the third rail.

The third rail is similar in shape and weight to that used on the stretch of track between East Weymouth and Nantasket Junction on the South Shore branch of the Plymouth Division of the N. Y., N. H. & H. R. R. R. In cross-section it resembles a flattened "A" and weighs 93 pounds to the yard. It is laid upon blocks of wood impregnated with insulating material. The blocks are only about one-half as high as those used at East Weymouth, allowing 1⅝ inches from the eave of the third rail to the tie, and in some places only 1½ inches. This reduction in the height of insulating block is due to the fact that no greater height could be allowed in view of the height of the service rails.

The top of the third rail is about 1 inch higher than the level of the tops of the running rails. The conductors are bonded, not by the ordinary leaf or stranded copper bond, but by plates of sheet copper ⅛ inch thick, 12 inches long and 4½ inches wide. These are fastened to the underside of the third rail joints by means of a drop-forged iron angle-plate bolted by 16 bolts, 8 for each copper plate, on each side of the third rail joint, the nuts being outside the rail. Each bond has a capacity of about 900,000 circular mils. The total bond at each joint having about twice the carrying capacity of the rail itself, while its measured resistance is less than equal length of the 93-pound third rail. One of the most striking facts in this installation is the absence of feeders, entire dependence being placed on the carrying capacity of the well-bonded rail.

On the Berlin branch are four grade crossings. On the New Britain and Hartford line there are 18. At all of these crossings the third rail is omitted, the circuit being continued underground by stranded bare copper cables of 500,000 circular mils and in some cases 850,000 circular mils. These cables are first drawn into creosoted wooden conduits filled with an insulating material made of petroleum residuum and asphalt. They are then laid in creosoted wooden troughs in turn filled with the same compound and then boxed over and buried. The broken ends of the third rail are fitted with wooden inclines or approach blocks to allow the shoe to rise upon the rail without danger of catching and breaking.

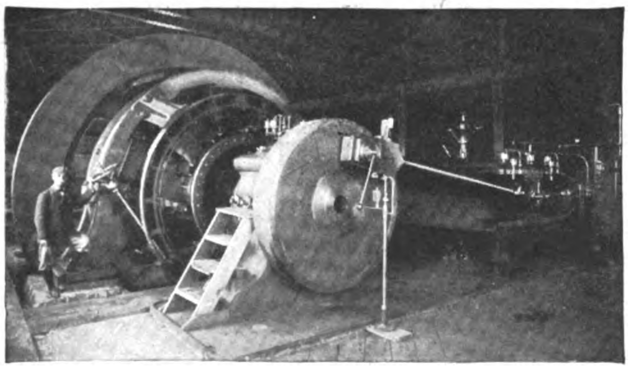

FIG. 3.—850 KILOWATT DYNAMO DIRECT CONNECTED TO 1,200 H. P. ENGINE.

The motor equipment will consist at first of five motor cars. These are open cars 50 feet in length used last season at Nantasket but deprived of the trolley. Each car weighs about 32 tons. Each is equipped with two G. E. 2,000 motors and two "L" series parallel controllers. The car cut-out is a K automatic circuit-breaker fixed beneath the hood. Each motor car is fitted with air brakes, two gongs and a chime whistle.

Air for the brakes and whistle is furnished by a vertical double cylinder air pump driven by a motor automatically controlled by special switch which is opened when the pressure in the main tank reaches 90 pounds and closed when it falls below that.

Contact is made with the third rail by means of sliding shoes. These are of cast iron 12 inches long and 4 inches wide, weighing about 20 pounds. They are suspended by two links from a casting fastened to a beam set immediately beneath the king pin of each truck, connection between motor and shoes being made by flexible cables. The distance between the two shoes is about 33 feet.

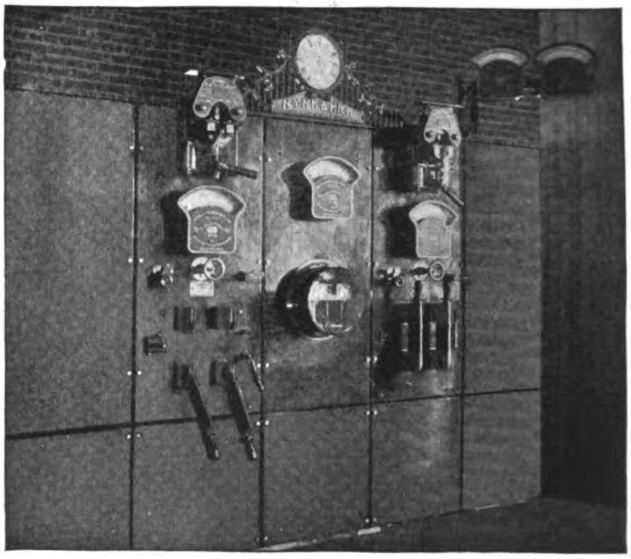

FIG. 4.—SWITCHBOARD.

Many of the grade crossings are wider than this and to avoid carrying the train over the crossing by momentum another shoe is fitted to each truck of the second car of the train, a connection running from this shoe to the motors. Thus by the time the last shoe has left the third rail at one end the first shoe is in contact with the next section of the rail.

The question of the safety of the public was not the least important which demanded the attention of the officials of the New Haven Road. In order to protect people from their own carelessness or absence of mind, the greatest precautions are taken. At Berlin and Hartford stations, the third rail section is fenced in on both sides. At New Britain, where the lines of the New Haven and New England systems converge, in addition to the fence, a method which almost amounts to interlocking is adopted. In the "Y" formed at the convergence of the roads, is the switchman's tower. From the section of the rail entering the station cables run underground to a switchboard in the tower, for which the third rail may be connected to or disconnected from the circuit. As the train comes to a stop in the station, the third rail is cut out, and is not thrown into circuit again until the outgoing train is ready to start. The chance of accident is thus reduced to a minimum.

Credit for this installation must be awarded to President Clark for the courageous advance he has made in the application of electricity to travel on the steam line; to Col. N. H. Heft, the practical chief of the electrical department, who laid out and supervised the installations at Nantasket, East Weymouth and Berlin, and to the General Electric Company, whose long experience and perfected apparatus rendered the installation possible.

PRICES FOR SAN FRANCISCO MOTORMEN.

The officials of the San Francisco and San Mateo Electric Railway have awarded six prizes that were offered as an incentive to their employés to take an interest in the property of the corporation. The motorman with the best record receives $40 and a silver badge with No. 1 engraved thereon. The motorman with the next best record receives $25 and badge No. 2. The third highest motorman receives $15 and badge No. 3. To the conductor with the best record $25 and a badge similar in design to that presented to the first prize motorman has been given. The conductor who stands next receives $12.50 and badge No. 2. The conductor third on the list receives $7.50 and badge No. 3.

ELECTRIC LIGHTING

ARTIFICIAL LIGHT; MODERN METHODS COMPARED—ELECTRIC-INCANDESCENT, WELSBACH, ACETYLENE.[1]—I.

BY PROF. D. S. JACOBUS.

Stevens Institute of Technology, Hoboken, N. J.

THE lecture was introduced by experiments to show the appearance of various colors when viewed by the different lights. Two surfaces of the same color were held up at an angle between two sets of lights, each set containing eight lamps or burners. The two sets of lights to be compared were placed at a distance of about 6 feet from each other on the lecture table. Screens were placed in front of the burners, to shield the eyes of the audience from the direct glare of the lamps. In the space between the lamps colors were shown on large pieces of cardboard, doubled over at the middle so that the two sides could be held at an angle to each other. This allowed one surface to be illuminated by one set of lamps and one by the other. The audience could observe each surface at the same time, and thus compare the colors as they appeared to the eye.

A second series of experiments consisted in viewing colors of a slightly different hue, which appeared of nearly the same hue when held in one position between two sets of lamps, and a widely different hue when the colors were reversed so as to be lighted by the opposite set of lamps.

Many colors appeared of a different shade when viewed by the acetylene and by the Welsbach lights. Some of the colors appeared brighter under the acetylene light than under the Welsbach, and this is especially so in the case of the lighter shades of pink(whereas the reverse holds true of some other colors. On holding the hand between the Welsbach and acetylene burners, the side of the hand illuminated by the Welsbach light appeared to be of a yellowish hue, and that illuminated by the acetylene exhibited the natural pink tint. The acetylene, therefore, made the hand appear more life-like than the Welsbach light.

TABLE I.

Kind of Light.		Candle-Power of Gas on the 5 Cubic Feet per Hour Basis.	Gas required per Hour for 16 Candle-Power in Cubic Feet.	Heat of Combustion of Gas in B. T. U. per Cubic Foot at 60° F.	Total Heat in B. T. U. for 16 Candle-Power per Hour.	Percentage of Total Heat Converted into Light.	Cubic Feet of CO_2 Produced by a 16 Candle-Power Light per Hour
1		2	3	4	5	6	7
Illuminative Water Gas	Flat flame burner..	20	4.00	700	2,800	0.6	3.4
	Welsbach	70	1.14	700	798	1.9	1.0
Acetylene		200	0.40	1,420	568	2.7	0.8
Incandescent electric ...		...	....	....	250	6.2	0.0

Ordinary gas, and the incandescent electric light also produced more lifelike tints when the experiment was made of holding the hand between them and a Welsbach lamp.

Experiments were described, which had been made before the lecture, in which the apparent tints, when viewed by the different lights, were compared with the tints when the colors were viewed by daylight. The acetylene flame was found to show the light pinks or flesh colors much more nearly in their natural tints, or their colors when viewed by daylight, then the Welsbach. The same results followed for incandescent electric light and ordinary gas, when burned in a flat flame, both of which brought out the lighter shades of pink more truly than the Welsbach. The experiments demonstrated that there is a very slight difference in favor of the acetylene over the incandescent light in bringing out delicate shades of pink, and that ordinary gas burned in a flat flame burner comes next in this respect.

Some colors other than pink were found to appear more nearly of their true tints under the Welsbach than under the other lights, in the experiments where the lights were compared directly to daylight.

CANDLE-POWER DEVELOPED PER CUBIC FOOT OF GAS. ELECTRICAL ENERGY TO PRODUCE THE ELECTRIC LIGHT AND PROPORTION OF TOTAL ENERGY TRANSFORMED INTO LIGHT. ALSO, RELATIVE HEATING AND CONTAMINATION OF THE ATMOSPHERE BY CARBONIC ACID FOR EQUAL CANDLE-POWERS.

The figures for the various methods of illumination are given in Table I, in order that they may readily be compared.

It will be seen, from the figures given in Table I., that acetylene gives ten times as much light as ordinary illuminating water gas when the latter is burned in a flat flame burner, and about three times as much when the latter is burned in a Welsbach burner.

The percentage of the total heat of combustion of the gas transformed into light is also greater for the acetylene than for the ordinary illuminating gas. For a given illumination the atmosphere is vitiated by the carbonic acid formed in burning the acetylene to a slightly less extent than when burning the ordinary illuminating gas in a Welsbach burner.

The figure for the candle-power of the gas on the basis of 5 cubic feet burned per hour, given in Table I., is from my own experiments. The figure for the Welsbach is derived from the results obtained in tests of both old and new mantles on the latest form of lamp, and is safe for ordinary practice, as it is nearer to that obtained with old mantles than to the results obtained with the new.

The candle-power given in the table is an average of the candle-power in a horizontal plane passing through the lamp center. The spherical candle-power is less than candle-power so measured, but the proportion between the spherical candle-powers would be about the same as the proportion between the candle-powers measured in a horizontal plane, or within the range of variation of the experimental results; so that comparative figures may be obtained by using the latter.

SAFETY-EXPLOSIVE PROPERTIES OF ACETYLENE.

If 3 per cent. of acetylene be mixed with air, an explosive mixture is produced. In the case of hydrogen 5 per cent. is required, and for coal gas 8 per cent. The maximum amount of acetylene that can be mixed with air to form an explosive mixture is 82 per cent., and the corresponding figure for hydrogen is 72 per cent.

It, therefore, appears that acetylene is more explosive than either hydrogen or coal gas. As the burners used for acetylene would discharge a less amount of gas—say one-fifth that of an ordinary gas burner—the accidental opening of a burner would cause the atmosphere of the room, as a whole, to be much less contaminated in a given time than with coal gas. On the other hand, acetylene gas is so much more nearly of the density of air than ordinary illuminating gas, that it will not be diffused as rapidly through the air in case of leakage, and will have a greater tendency to collect in a partly enclosed space, and thus cause an explosion in case the gas were ignited.

(Experiments were made in which acetylene and ordinary illuminating gas were exploded when mingled with air. The gas was allowed to escape from a burner into a tube placed at an angle. The explosion produced by the acetylene was much more severe than that produced by the illuminating gas.)

In regard to the explosive properties of acetylene itself, much may be said. When carbon and hydrogen unite to form the compound called acetylene, heat is absorbed. According to Berthelot, if gaseous acetylene, under a pressure of about 15 pounds above the atmosphere, or over, be ignited by a spark, or by a heated platinum wire; it will decompose explosively without the presence of air. The explosion becomes more violent as the initial pressure is increased. In exploding, the carbon and hydrogen are dissociated, and the heat absorbed in the original formation is set free. This heat, according to Berthelot, is sufficient to increase the temperature (provided the pressure be kept constant), about 5,000 degrees Fahrenheit, or to increase the pressure to eleven times the initial (if the volume be maintained constant). At atmosphere pressure, however, Berthelot found that acetylene gas containing no air could not be exploded; for if a spark were generated in it, or even if fulminate were exploded in it, there would be no decomposition into the elements of carbon and hydrogen, except near the point where the spark, or fulminate, acted on the gas.

Berthelot also found that liquid acetylene, as transported in tanks under pressure, would explode as readily as the gas. In one case, he exploded liquid acetylene in an iron tank by means of fulminate of mercury, and shattered the tank to pieces. He also made experiments to determine if blows or shocks would start explosions in cylinders of the liquid. He found that a shock would not of itself start an explosion, but that when steel cylinders of the liquid acetylene were smashed the blow was usually followed by an explosion, probably produced by the sparks generated by the friction of the pieces of broken steel. He states that local elevation of temperature may produce compounds evolving heat, and finally cause an explosion; and also that the sudden opening of a stop-cock may produce local heating and an explosion.

---

[1] A lecture delivered before the Franklin Institute, March 12, 1897.

The investigations of Berthelot on the explosive properties of acetylene show how dangerous the gas is when stored under pressures higher than that of the atmosphere. That such is the case is borne out by the fact that a number of accidents have occurred where it has been used under such conditions.

THE NOWOTNY ENCLOSED ARC LAMP.

THE accompanying engravings represent the Nowotny long-burning arc lamp, the latest to claim attention in this recent development of arc lighting.

In the design of this lamp special pains have been taken to avoid all rods, chimneys, clockwork, gearwheels, springs, and side rods and the outer globe-stand which cast shadows. As will be seen, the arc is entirely inclosed by the inner globe, which is in turn surrounded by the outer globe, preventing the access of fresh air, thus prolonging the life of the carbons 125 to 150 hours. The carbon is gripped directly without the intervention of any carbon rod; the clutch is composed of four porcelain balls, maintained in position by a retaining receptacle and performing all the functions of a ball-bearing, arc-maintaining device. It is impossible for the carbon to slip except at the proper time when feeding takes place.

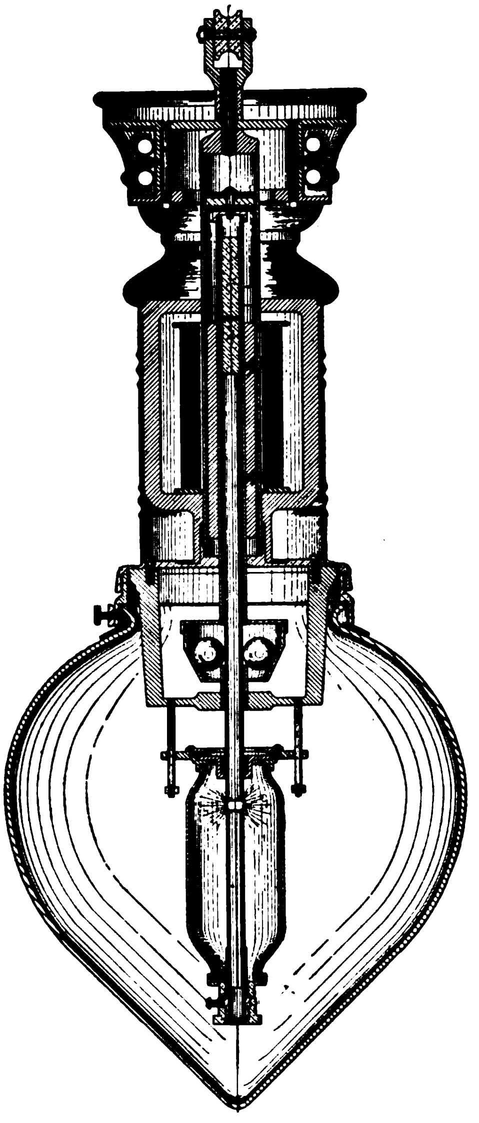

Fig. 1.—The Nowotny Long-Burning Enclosed Arc Lamp.

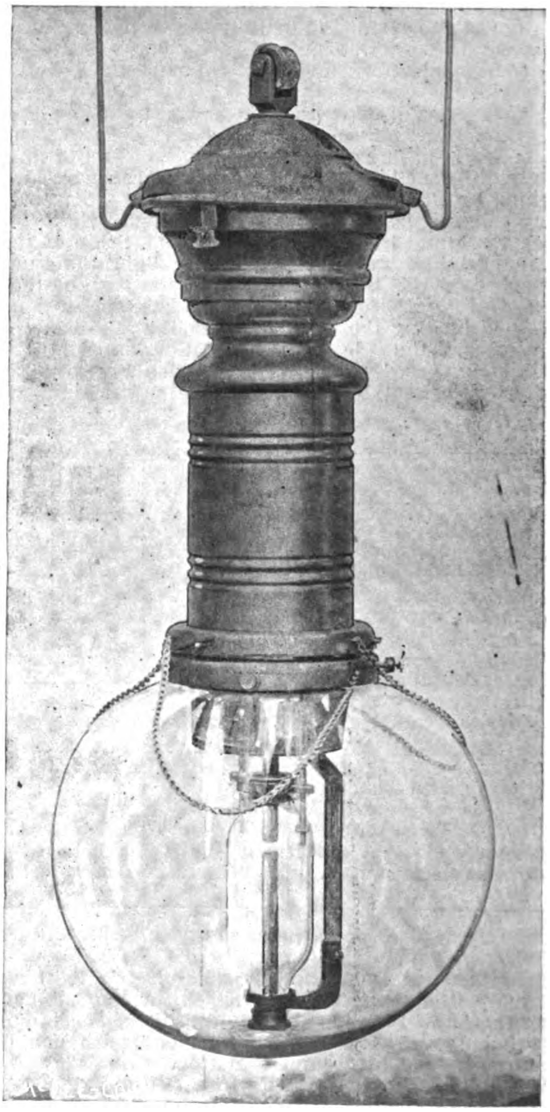

Fig. 2.—The Nowotny Long-Burning Enclosed Arc Lamp.

The general arrangement of this lamp is such that it is extremely easy for even an inexperienced person to re-carbon and take care of it, and there are no adjustments to get out of order. Owing to the unique manner in which the inner globe is held in position there is ample room for the glass to expand and contract without danger of its breaking, and the breakage of inner globes is rare. The outer globe is supported by a ring at its top, which when lowered is held by three chains in such a manner that the globe can be raised or lowered without detaching it. The lamp is ornamental in appearance for both interior and exterior service. The outdoor lamp shown in Fig. 2 is fully weatherproof, preventing any moisture from getting into the mechanism. It is furnished to consume 4 amperes, 4½ amperes and 5 amperes at 80 volts across the arc, with 110 volts on the line.

This lamp is manufactured by the Nowotny Electric Company, 208-212 Lawrence street, Cincinnati, O.

ELECTRIC LIGHTS AT THE NASHVILLE EXPOSITION.

MR. HERMAN JUSTI, of the Nashville Exposition staff, sends us the following data as to the lighting from the plant illustrated and described in The Electrical Engineer May 12:

There are burning on the roofs 12,000 8-candle-power lamps. These lamps require a very small amount of current and the effect is equally as good as 16 candle power would make. The Commercial Building has 1,600 lights on the roof. The lines of the cornice have been followed; all arches have a row of lights above them and the dome alone has 680 lights. The building being of pure white, the effect is enchanting.

The Transportation Building has 620 lights on the roof; the Agricultural Building has 1,600 lights on the roof, and is considered the best effect on the grounds. The Machinery Hall has 580 lights on the roof; the Negro Building has 479 lights on roof; the Rialto has 540 lights in colors. They are exhibited in curved lines, following the line of the ridge and produce a most strikingly attractive effect. The Mineral and Forestry Building has 702 lights on roof; the Auditorium has 840, the Woman's Building has 280, the History Building has 294, the Parthenon has 280 on roof; the Educational Building has 610.

There are a great number of private lights on the grounds and streets, and the number is being constantly augmented.

All wires within the park proper are under ground. The wire consists of 37,000 feet of New York Safety Insulated Wire Co.'s lead-covered cable, and on the entire underground system there has been no trouble whatever, as new lines have been followed here in the installation of the underground.

There are two power circuits 500 volts and 110 volts constant potential. The buildings are thoroughly wired for power circuits. They have in operation at present about 20 small motors from ¼ to 1 horse power; two 5-horse-power motors. There will be added two 30-horse-power motors and a great many smaller ones.

The superintendent, J. W. Pentecost, has been extremely efficient, and has had immediate charge of the work from its inception.

ONONDAGA DIRECT CONNECTED GENERATOR.

PERHAPS the best lighted establishment at Syracuse, N. Y., is the immense shoe store of S. Rosenbloom & Sons. This enterprising concern have installed their own electric lighting plant, consisting of a 75-kilowatt Onondaga direct connected dynamo, built by the Onondaga Dynamo Company, of Syracuse, N. Y. The unit, shown in the accompanying engraving, Fig. 1, consists of a six-pole machine mounted on one base with the engine and thus affording a rigid connection, conducing largely to the noiseless operation of the machine.

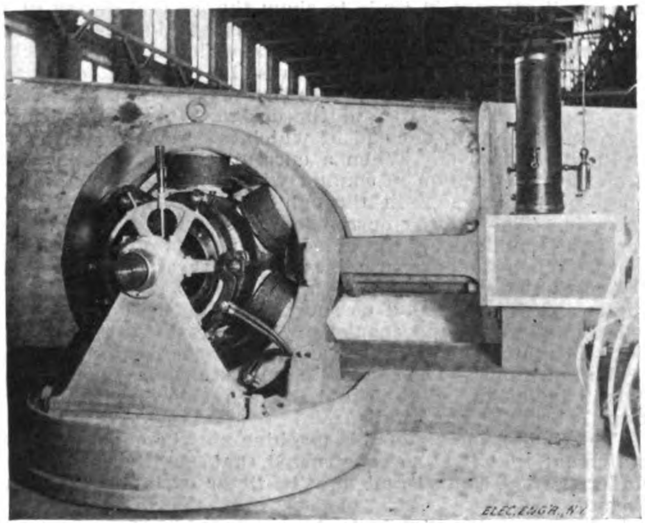

FIG. 1.—ONONDAGA DIRECT CONNECTED GENERATOR.

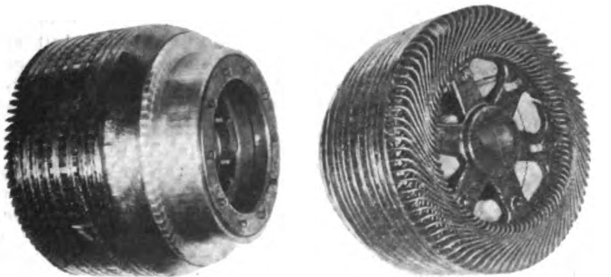


FIGS. 2 AND 3.—ARMATURE OF ONONDAGA DYNAMO.

The armature and engine are both so well balanced that scarcely a tremor is perceptible when the unit is in operation, the speed being 265 r. p. m.

In this machine, as in all of those built by the Onondaga Dynamo Company, the magnet yoke is made of a special mixture of gray cast iron, while the magnet cores are of soft charcoal forged iron. These cores are cast solid in the magnet yoke, thus avoiding the necessity for bolted joints.

Special attention has been given to the construction of the armature to secure ventilation. The engravings, Figs. 2 and 3, show two views of the armature, indicating how this is secured. The armature coils are formed to standard shape on a "former"; no end connectors are required except the connection with the commutator. The armature when complete allows of a free circulation of air between the coils at both ends. As a result of this construction the machine can run at a temporary overload of 25 per cent.

The Onondaga Dynamo Company build dynamos and motors from ¾ horse power up to 75 kilowatts and over for voltages of 125, 250 and 500 volts direct current. Their "Clover Leaf" type of belt driven machines have already won an enviable reputation.

NEWS AND NOTES.

THE HOLLAND SUBMARINE TORPEDO BOATS.

BY ROBERT McA. LLOYD.

THERE has been so much said in the newspapers during the last year about the two Holland submarine torpedo boats being built at the Columbian Iron Works, Baltimore, Md., and the Crescent Ship Yard, Elizabethport, N. J., and so little actually done with the boats, that the public have very little faith in the promises of the apostles of this kind of navigation. The boat at Baltimore has been two years in process of construction, under government supervision, and may be finished during the coming summer; the one at Elizabethport was contracted for in November of last year (1896) and has been rapidly completed, so that within a few weeks it will be ready for trial, having been launched on Monday.

The Baltimore boat is much the larger, and more powerful, but since it will not be finished for some time, I shall refer to it very briefly. It is 85 feet long and 168 tons displacement. On the surface it will be propelled with 1,500 horse power of steam engines, and under water by an electric motor of 70 horse power, getting its current from a storage battery which has a six-hour capacity at that rate. This boat has a heavy armor turret and a great quantity of machinery and is armed with two torpedo tubes in the bow.

The Elizabethport boat has the advantage of greater simplicity both as to construction of the hull, and equipment of machinery, and will have some features of importance in the way of armament not included in the other. It is 53 feet long with a displacement of 74 tons and a diameter of 10¼ feet. It is propelled by a single screw, and has for power a large gas engine, and an electric motor with a storage battery that will deliver 150 horse power for one hour, driving the boat at 14 knots submerged or 50 horse power for 6 hours, giving a speed of 8 knots submerged. The speed in surface running will not be so great for the same power. The boat has a small telescopic turret for observation and effective devices for handling under water. She has a single 18-inch torpedo expulsion tube in her bow, an aerial dynamite gun forward and a submarine dynamite gun aft. She will be able to dive and run at any any depth below the surface down to 100 feet and can be instantly adjusted to maintain any fixed depth while running. If running under a fleet in deep water, she would of course, need at least 30 feet of clear depth over her, but when attacking a ship might take a higher level so as to be able to come quickly to the surface now and then for an observation. She has a powerful hull and could stand the pressure at 150 feet if necessary, but for fighting purposes would never be required to go to a great depth.

The many details for ventilating, trimming, diving, steering and propelling cannot be described here, but inasmuch as electricity plays such an important part in these operations, electrical engineers may well consider the launching of this boat an event in the history of electrical development. Submarine boats have been built and tried many times in the past two centuries, and of late years have received considerable scientific treatment, but nothing of practical value has been accomplished until recently, when the electric motor and storage battery have made the problem easier to solve. The history of Mr. John P. Holland's tireless efforts with the government, and with capitalists, to put the submarine boat business and submarine warfare on a practical basis would make interesting reading, but a point has now been reached when it is not too much to predict that naval warfare is about to be revolutionized, and electricity is to find a new and large field. If the boat to be tested next month is a success at all, our government will order a large number of them this year and may possibly use hundreds of them, which, of course, means a large quantity of electrical apparatus.

Then there is a large field for their use in wrecking operations and in harbor surveying; in submarine exploration, mining, building, etc., and in all these boats the propulsion, lighting, pumping and other mechanical offices will be performed by electricity. There may be also large submarine battleships but it seems probable that nothing could be accomplished by them that would not be within the capabilities of a 100-foot boat.

In the serious business of war the submarine torpedo boat has such a manifest advantage that the only question ever raised is, can you build one? A few more weeks will apparently settle this question in the affirmative, and the indications are that with every government in the world armed with submarine ships within the next ten years, naval warfare will become very unpopular.

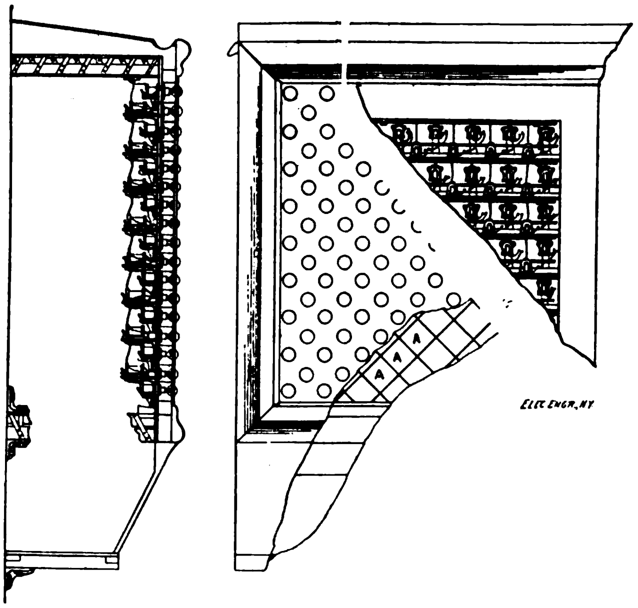
In the fascinating pursuit of lost treasure, and the exploration of submarine property, the submarine boat will doubtless become a great aid to the wrecker and diver, and make possible the lifting of ships that otherwise could not be reached and add much to our knowledge of the sea. Most of the wrecks that are going down every day, lie less than 250 feet from the surface—not too great a depth for submarine boats—and with their aid in sweeping chains and fastening them to pontoons, a much larger proportion will be recovered than in the past.

To enumerate further the possibilities now awaiting fulfillment seems to be taking up space which should be devoted to the technical details of this subject, but the machinery is so simple that it does not compare in interest with the boat as a whole, or its mission. Dynamos, motors, storage batteries, air compressors, gas engine, ventilating pump, bilge pump, steering engines, gauges, valve controllers; nothing worth writing about half so much as a single dive will be in the waters of New York Bay a few weeks hence.

AN AUTOMATIC ELECTRIC ADVERTISING SIGN.

BY FARLEY G. CLARK.

IN the design of the apparatus shown in the accompanying drawings, the inventors, Chas. H. and F. G. Clark, drew up a set of specifications representing what was necessary in an ideal sign, fulfilling all the commercial requirements. The first specification calls for a sign capable of showing perfectly formed and spaced letters of different sizes and styles. The second, for a controlling apparatus which will allow the circuit through the lamp to be made or broken at any instant, independently of any other lamp. The third, for a perfectly automatic arrangement in which a number of designs may be shown on the sign mat according to a prearranged plan which may differ from night to night. The fourth and last calls for an apparatus which will be accepted as safe by the Board of Fire Underwriters. Without showing the different steps taken in perfecting a machine to meet these specifications, we will proceed at once to its description.



FIGS. 1, 2 AND 3.

The Automatic Sign.—Figs. 1, 2 and 3 are views of the sign mat, being respectively the front, side and rear elevations. It will be seen that this follows the Schneider plan of showing the design upon a mat of lamps. Referring to Fig. 1 we note that the lamps are equally spaced, and arranged in rows at an angle of 45 degs. to the ground line. By using the lamps nine deep, as shown in the drawing, perfectly formed letters may be shown. Each lamp is separated from the others by a partition, as shown by A A, so that the reflection of a lighted lamp, upon its neighbors, will not produce the hazy effect noted in signs of this description.

Figs. 2 and 3 show the positions of the relays, and in Fig. 2 a small attempt is made to show the general design of the sign. A generous amount of space is left between the sign mat and building to facilitate repairs, which, although not considered as probably necessary, must be provided for.

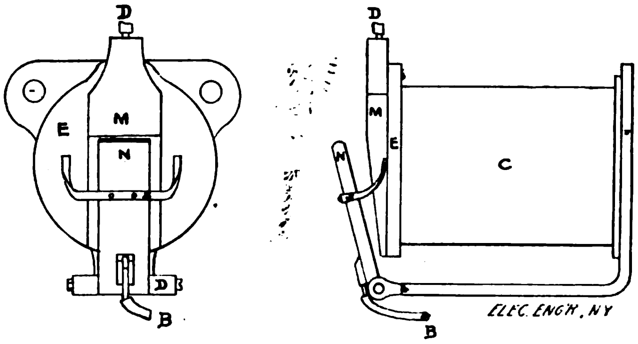


FIG. 4.

The Relay.—In Fig. 4 we have two views of the relay which is a fundamental feature of the design. In the side view C represents the coil, one end of which is connected to the controlling mechanism. When a current is sent through C the armature N is drawn in contact with M, thus completing the main or lighting circuit through the lamp which the relay controls. The lighting current comes from the positive main through D, and passes through B and the lamp to the negative main. When the current ceases to flow through C, the spring S causes the armature N to break contact, thus putting out the lamp. In order that no short circuiting may occur, an insulating piece E and insulating bearings D are used. The parts M and N are made of tempered copper or a brass alloy.

The Controller.—The controlling mechanism is shown in Figs. 5 to 9 inclusive. Figs. 5 and 6 are a side and front elevation; 7, 8 and 9 are details.

The whole principle of this machine may be embodied in the statement that it is so constructed that each lamp is always under perfect control and may be lit or extinguished at any instant.

Referring to Fig. 6, which shows a machine for operating a 3.200-lamp sign, we see nine drums which are kept in synchronous motion by the motor working a worm and train of gears.

Each lamp, or rather relay, has its contact point on one of these nine tiers, as shown by the heavy black and the fine lines, though Fig. 9 shows them full size. Each tier, beginning at the top, carries the contact points for a line of lamps on the sign, and as the mechanism of the nine parts are duplicates of each other, a description of one will suffice for all.

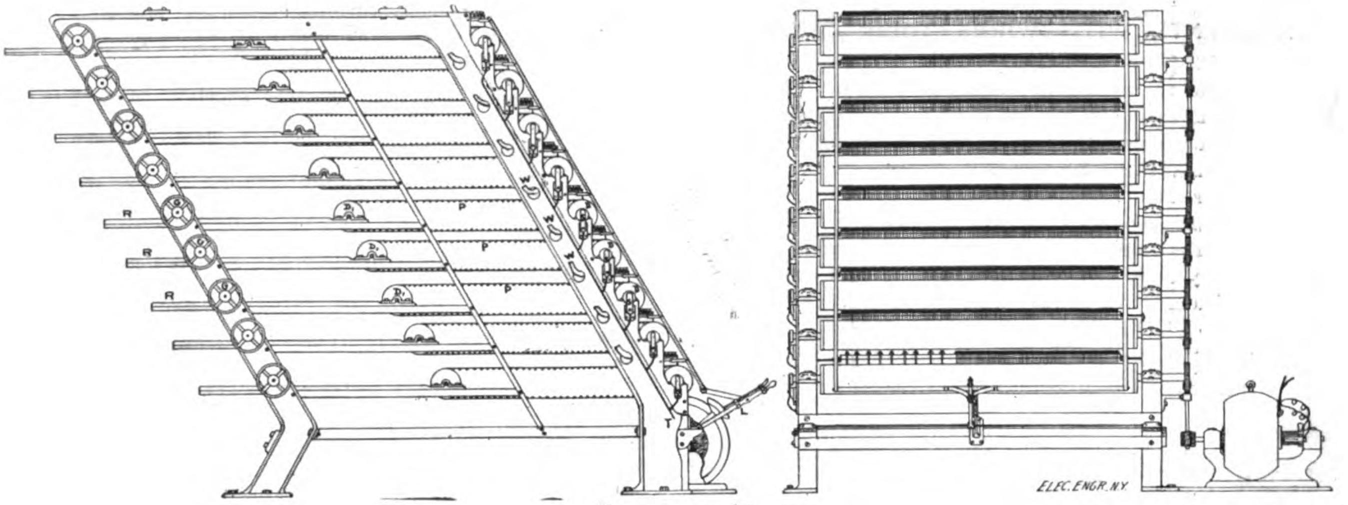
In Fig. 5 D and D are drums carrying the design, and P is the design itself. The design is divided into nine parts and each part consists of a strip of thin and pliable but strong insulating material. Upon each of these strips or sheets a part of the design is represented by slots cut in the material. These sheets are carried over D and D_1 and are between D and the contact points.

The drum D is connected, through S and T, to one pole of a dynamo running at a potential of about ten volts. The other pole is connected with each of the relays. It will now be readily seen that when a slot in the design sheet comes under one of the contact points, that point is thrown in contact with the drum and consequently a current sent through the relay, which in turn closes the circuit through its lamp.

In Fig. 5 D is the driving drum D_1 the drag or follower, and rests on a rack R which can be moved by the gear S. With the drag moved nearer to the left upright of the frame, more designs could be put on the carrier and a longer time would elapse before the designs would begin to repeat.

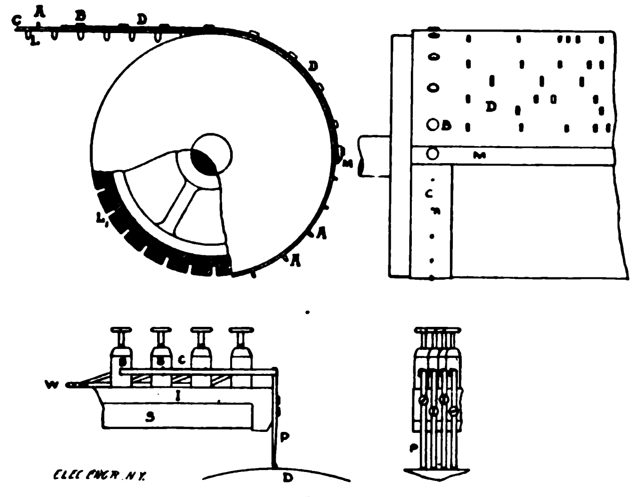
The rod marked I is used in conjunction with L to raise the shelves carrying the contact points. This mechanism is added to keep the points away from the drum when the machine is not running. The wires connecting the contact points with the relays are brought out on the side of the frame and are represented by the cables W, W, etc.

The Drum and Carrier.—Figs. 7 and 8 show the driving drum, design sheet, and carrier in detail. The carrier is a thin ribbon of soft steel, having teeth L on its under surface, which fit into the gear L_1 on the drum. This arrangement is similar at the other end of the drum and insures an even motion to the carrier. On the upper surface are little points A which are made to project through the design sheet, and carry a thread so that a cap B may be screwed on. With the design sheet held thus firmly there is little danger of its becoming warped.. Another detail is what, for want of a better name, will be called a guide. It is represented by M and is a delicate but very rigid strip of steel which is attached to the edge of the design sheet and to the carrier. Its duty is to prevent any sag in the center of the sheet. The slots in D, Fig. 8, give an idea of the appearance of the design sheet.



Figs. 5 and 6.

The Contact Mechanism.—In Fig. 9 I is the insulation between the steel shelf S and the contact mechanism. The tempered steel points P are connected through C and B to the wires W, which run to the relays. These points are so designed that they will give a quick action and make and break contact without perceptible sparking. While insuring good electrical contact they are not so stiff as to distort the design by an undue drag upon the design sheet.



Figs. 7, 8 and 9.

The large contact points on the lower tier of the controller, as seen in Fig. 6, are used to operate auxiliary controlling devices, as, for instance, to increase or diminish the speed of the motor, and to compensate for a decrease in the call for current by the relays. This latter is necessary to prevent sparking at the contact points when a large number of lamps are suddenly switched off.

Wiring Diagram.—In Fig. 10 we have a diagrammatic representation of the wiring plan. The auxiliary dynamo, generating the currents for the relays is represented by A. R is the compensating resistance, D the drum, C C the contact points and R R, the relays. M is the main or lighting dynamo and L L the lamps. The simplicity of a single part of this apparatus is apparent at the first glance.

In preparing the design sheets a very simple machine, somewhat similar to that used in preparing the cards for a Jacquard loom, has been designed. With it, the designs needed for a five-hour run can be made in a few moments.

For showing bulletins or election returns, the controlling machine described could be used, or a machine of the typewriter pattern somewhat similar to that designed by Norden would answer. The possibilities in the effects which may be produced upon the sign by the automatic controlling device are innumerable. As examples it will be sufficient to mention the possibilities in outline sketches, and geometrical figures in motion, such as are produced in firework displays.

The question to be answered by the reader is, Does the apparatus described fulfill the requirements of the specifications? If it does, and it has been the aim of the writer to show it, it is unnecessary to speak of the place it will occupy in the advertising field of the future.

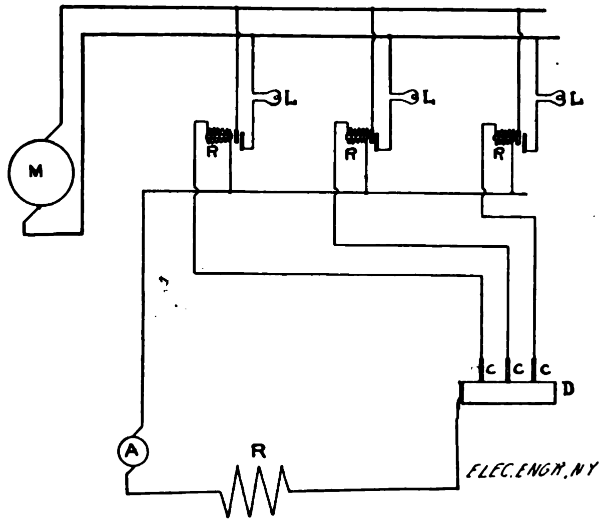


Fig. 10.

TOOK AN ELECTRIC LIGHT TO BED.

A dispatch from Lexington, Va., of April 22 says: A Lynchburg drummer nearly caused a serious conflagration at one of the leading hotels here the other night. The weather was cold, and he took an incandescent light, which had a long connection to it, in his room, wrapped a bed sheet around it, and placed it in the foot of the bed to keep his feet warm. He was awakened some hours afterward by smoke and roasted feet. The light had set fire to his bed, which was in a full blaze, and was extinguished after much difficulty. The globe to the light had become soft and plastic from the intense heat and assumed an almost flat shape.

BOSTON WIRES.

According to the report of the Boston Superintendent of Wires the total number of fires last year due to electrical causes was 85, of which 12 were on the outside and 22 inside of buildings; miscellaneous number 21, and 13 injuries were recorded and 3 deaths. No fire was caused by wires or appliances that had been approved by the wire department. The total amount of street conduit now laid is nearly 92 miles. There are about 566 miles of single duct, 65 miles of Edison tube and about 244 miles of single conductors in them; besides there are about 36,277 miles of single conductors in cables.

ACCIDENTS WITH WIRES—THEIR CAUSE.

BY W. S. ECKERT.

APROPOS of the article appearing in the May 12 issue of the Engineer on "Accidents With Wires," it seems to the writer that there ought to be some way of reducing the number of accidents there recorded.

It has been shown that hard drawn copper wire, having 98 per cent. of the conductivity of pure copper, lacks tensile strength and absolute reliability from a mechanical point of view. Not only does such wire stretch under its own weight, the diameter decreasing always and with it, also, its mechanical resistance, but the slightest abrasion, caused in transportation or when putting the wire in place, will bring about complete rupture when the wire is subjected to strain. The one important mechanical advantage of copper is that it does not corrode.

Galvanized iron wire and steel wire rust, and, as the points of oxidation increase the mechanical resistance decreases. These wires, when first put into service, are, as compared with copper, but poor conductors, but, when oxidized, they lose a large part of their initial properties. It has been found by experience that neither iron nor steel wires can be relied upon, either electrically or mechanically, for any considerable time; they are, therefore, really more costly than a high-grade conductor in the end.

Bi-metallic wire, composed of copper and steel—steel center with solid copper surrounding it—seems to meet the mechanical deficiencies in copper wire, though, for the transmission of direct currents, at the expense of conductivity. In view of the many accidents caused by the breaking of wires, and the liability of damages therefor by the operating companies, it is a question whether it is not best to sacrifice a certain portion of the conducting qualities of the wire rather than the strength. Bi-metallic wire, like copper, does not corrode, neither does it stretch. It retains its electrical and mechanical qualities always, as shown by the experience of the Postal Telegraph Cable Company with wire of that description, put up in 1883, and which, according to reports of the officers of that company, tests as well to-day as it did fourteen years ago.

The conductivity of bi-metallic for the transmission of direct current is, substantially, 65 per cent. of that of solid copper of equal diameter; its strength, practically four times its weight per mile; but, as mentioned before, this strength is retained, while wires of copper, iron or steel commence to deteriorate when first put into service. The conductivity of bi-metallic wire is sufficient to meet all ordinary uses; its strength will more than counteract the deficiency in electrical transmission. Railway companies, using high voltage and bare wires, require a strong and rigid trolley wire, and, if feeders are employed, bi-metallic, which has both strength and rigidity, also has sufficient conductivity to operate the cars. Where guard wires are specified, bi-metallic will be found suitable for that purpose; it neither corrodes nor stretches, remaining strong always.

Telegraph, telephone and other wires must, necessarily, be carried over railway wires at many points, and such wires are always liable to be broken in storms or by other wires or objects falling upon them. To minimize the danger of falling wires it seems best to strengthen the wire—apparently bi-metallic meets the requirements. Telephonically considered, bi-metallic wire is superior to copper wire, and the users of that wire have secured very good service which, at the same time, is reliable. Bimetallic wire, possessing about 50 per cent. of copper, is cheaper than copper wire.

X-RAY PHOTOGRAPHY.

IT may be interesting to note, says William Webster, in "Nature," that it is possible to take shadowgraphs (so-called) instantaneously without any special arrangement of induction coil or deviation in the form of Jackson tube. The apparatus used consists of 10-inch Apps' induction, coil, a Jackson focus tube supplied by Messrs. Newton (one of a set of twenty-five I have in my possession), and a set of small secondary batteries, about 30 ampere hour capacity, six cells in the set. The induction coil is of the ordinary type with ordinary commutator. For the purpose of obtaining these results in such short exposures, a special choice of tube is necessary, working the tube for a considerable period before desired condition is arrived at, and that condition judged by experience, for no ampere measurement will give the information. The tube must be strongly heated by a spirit lamp, and when the desired condition (tube being of course connected with coil) is arrived at, the exposure must take place.

(1) By instantaneously turning current on and off.

(2) By interposing a ½-inch iron plate between tube and object to be shadowed, removing plate for the exposure.

Having carefully timed the exposures, I have been able to repeat the experiment with assured success. For some time past I knew that hands and arms of children could be taken in from twenty to thirty seconds, but have now succeeded in taking children's hands in half a second (showing all bones and cell tissue of bones), and adults' hands, bones of wrist, and even arms, with exposure of only one second, again showing cell tissue of bones.

ELECTRICAL VIBRATIONS OF MERCURY.

The following observations, recorded by E. Braun, in "Nature," were made with a globule of mercury, about 1½ cms. in diameter, placed in a photographic developing dish containing some ordinary tap water, the mercury being well covered with water. A 4-volt accumulator of 6 ampere-hours' capacity supplied the current. Two wires from the terminals served as anode and cathode; the cathode had a short piece of fine wire attached, and this was so adjusted that it only just touched the mercury.

(1) When the circuit was completed by dipping the anode into the water, the mercury, after a few seconds, became visibly flattened.

(2) If the circuit was broken, or the mercury became detached from the cathode, it at once regained its original shape.

(3) When the circuit was completed, and the mercury becoming flattened broke away, it was thrown into a regular and continuous vibration.

(4) The frequency and amplitude of the vibrations depended on the distance of the anode from the cathode, the frequency and amplitude increasing as the anode was brought nearer.

(5) If the current was reversed, thus making the cathode an anode, the vibrations were not produced.

(6) The vibrating mercury generally retained its circular shape, but sometimes it became almost square, or took the shape of a cross, which seemed to be produced by a rapid motion alternating at right angles.

(7) The water was thrown into circular waves, which corresponded to the vibrations of the mercury.

(8) If the circuit was broken, and an interval of time was allowed to elapse, and then again completed, a decided lag was observed between the "making" of the circuit and the flattening of the mercury. If no appreciable lapse of time took place between "make" and "break," the response was instantaneous.

LES APPLICATIONS DE L'ELECTROLYSE A LA METALLURGIE (The applications of electrolysis to electrometallurgy).—By M. U. Le Verrier, Paris, Gauthier-Villars & Fils. 57 pp. 9 x 5½ in. Illus. Price, $1.00.

A concise treatsie on the practical application of electrolysis to metallurgical operations, comprising galvanaplastics, refining metals, treatment of minerals and electrolysis of molten salts.

ELECTRICITAET UND LICHT (Electricity and Light).—By Dr. O. Lehmann, Braunschweig, Vieweg & Sohn. 390 pp. Illus. 9 x 6 inches. Price, $2.80.

This work gives an introduction into the quantitative determination of electric power and light. All measurements required by the electrician are exhaustively treated and clear deductions show the origin of all formulas used in calculating force and effect.

This work constitutes one of the best treatises on the subject which we have yet seen. Its illustrations are particularly well done and very helpful to the understanding of the text.

SOCIETY & CLUB NOTES

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Secretary Porter writes us: The Trunk Line Association, the New England Passenger Association, the Central Passenger Association and the Southern Passenger Association have made a rate of a fare and one-third, on the certificate plan, from all points in their territory to Niagara Falls and return for delegates to our twentieth convention, to be held at Niagara Falls June 8, 9, 10. In purchasing tickets delegates should ask for a certificate which will entitle the purchaser to be returned at one-third the regular fare.

The arrangement for a special train has been a somewhat perplexing question, owing to the desire that our members should enjoy the best possible service at the lowest possible rate. After long and continuous negotiations, a most satisfactory arrangement has been made with the West Shore Railroad to run a special train of vestibuled parlor, library and dining cars, leaving New York (foot Forty-second street, North River, at 10:16 a. m., and foot Franklin street 10 a. m.), Monday, June 7. Tickets to return will be via West Shore Railroad or New York Central and Hudson River Railroad, thus enabling the delegates who take this train to enjoy the view of both sides of the river if they so desire.

The daylight run was decided upon owing to an almost unanimous request on the part of our members, on account of the large number of ladies who propose honoring us with their presence. The special train has always been one of the features of our conventions, and this one promises to excel any of its predecessors, even to providing a souvenir for the ladies.

Price of tickets to Niagara Falls, including parlor car seat, $10. For ticket and parlor car accommodation, apply to C. O. Baker, Jr., 136 Liberty street, New York, master of transportation.

NEW YORK ELECTRICAL SOCIETY.

The annual meeting of the society and election of officers will take place at Columbia University, Madison avenue and Forty-ninth street, on Thursday, May 20. Mr. H. Barringer Cox will lecture on "The Direct Conversion of Heat Into Electricity." A brief review will be given of the history of thermo-electric generators; the reason of previous failure in this direction; the real problem of thermo-electricity; the practical mission of a successful device. Thermo-electric generators will be shown in actual operation, furnishing current to fan motors, X-ray outfits, medical apparatus, telegraph sets, annunciator systems, and other devices in ordinary use and every-day demand. The regular business of the meeting will be taken up at 7:45 p. m., and the lecture will commence at 8.

MARRIED

STACEY-PARKER.

On May 5, at Evanston, Ill., Mr. T. I. Stacey, the estimable secretary and treasurer of the Electric Appliance Company, of Chicago, was married to Miss Lillie Parker, of Evanston, at the St. Mark's Episcopal Church in that city, where they will take up their residence on returning from their honeymoon.

PERSONAL

MR. C. H. WILMERDING announces that he is about to sever his connection with the Chicago Edison Company, and to open an office in Chicago, at 139 Adams street, as designing, constructing, supervising and consulting engineer, more particularly with reference to the planning, remodeling and complete installation of central station and isolated electric lighting, railway and transmission plants, and the underground distribution of electric currents, embracing also the supervision, in an advisory capacity, of the operating of existing plants with a view to improved economy and greater efficiency. His experience in these branches as general manager for five years of the Chicago Arc Light and Power Company, general superintendent for the past four years of the Chicago Edison Company, and president for the past eight or nine years of the Chicago Sectional Electric Underground Company, and in various civil, mechanical and electrical engineering undertakings prior to his association with these companies, warrant him in giving the assurance that work entrusted to him will be executed in a proper and satisfactory manner, with a full knowledge of the latest and most approved methods and appliances, and the advantages of a daily intimacy with their good points and their faults.

MR. J. J. FOWLER, long time general manager of the Southern Bell Telephone and Telegraph Company at New Orleans, La., has resigned and has been succeeded by Mr. J. Sitzenstatter, of New York, well known in the Bell telephone service.

MR. FRANK C. MASON, superintendent of the police telegraphs in Brooklyn, N. Y., and a leading Mason in this part of the country, has been elected president of the Aurora Grata Club, the central and powerful Masonic organization of that city. Mr. C. E. Stump and Mr. E. A. Leslie figure prominently in his cabinet.

MR. H. C. WYBRO, of Wybro & Lawrence Company, Los Angeles, Cal., is a visitor East, and has been spending a week in New York. The concern do a large business in electrical and steam apparatus, and the brisk condition of trade in Los Angeles keeps them very busy. They are just now extending the Anaheim municipal plant, putting in a 60 kilowatt Warren alternator, a 100 horse-power Fisher engine, and a 125 horse-power Stirling boiler, with oil burning furnace.

EDUCATIONAL

MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

Entrance examinations for the Massachusetts Institute of Technology will be held on July 1 and 2 at Boston; New York, Fifth Avenue Hotel; Philadelphia, Lafayette Hotel; Chicago, Medill High School, and elsewhere. To be admitted as a regular student in the first-year class the applicant must have attained the age of 17 years, and must pass satisfactory examinations in algebra, plane geometry, advanced algebra, or solid geometry, French or German, English and history. Detailed information can be had by applying to H. W. Tyler, Ph. D., secretary Massachusetts Institute Technology, Boston, Mass.

THE STOCK MARKET

VACILLATION.

The general conditions of finance and trade remain vacillating and oscillatory, some things being good, others bad. The financial markets have been affected by the gold exports, and pig iron has been lower, but the crop reports from the West are very encouraging, and the railroads and particularly the express companies report a brisker distribution of all classes of goods.

In electrical securities, the main feature of the past week was the Berliner decision which sent American Bell telephone stock up 10 points, from 222 to 232, a gain that it bids fair to hold; while other "old line" telephone stocks have also gained in strength and are in demand. On sales of 44,312 shares Western Union gained somewhat from its recent decline, and closed at 76¾. General Electric is extremely quiet around 31. It is thought that the management is repressing any tendency to buoyancy in the stock, preferring to see a slow advance on established gains in output and profit. Local lighting and railway securities throughout the country are dull, many quotations being lower than they should be.

COPPER.

The Boston "Globe" says, regarding the copper market: The recent large sales of copper are said by pretty confident authorities to aggregate between 15,000,000 and 20,000,000 pounds at 11 cents. These sales were not only by the Calumet and Hecla, but by other companies, although the Calumet and Hecla was the largest seller.

The Franklin Mining Company sold 200,000 pounds of copper at 11 cents, and has refused to accept same price for more.

The treasurer of several copper mines says: "We are bid from New York, by telephone, 11 cents cash for round lots, and there is a bid for a big lot for each month of July, August and September. It seems to me that copper has started and will go higher."

ANNUAL REPORT OF THE CHICAGO EDISON CO.

THE report of the Chicago Edison Company for the fiscal year ending March 31 shows a gain in both gross and net as compared with the preceding year. For both years the earnings applicable to dividends amounted to a fraction more than 8 per cent on the outstanding capital stock. The figures for the two years are as follows:

	1896-97.	1895-96.	Increase.
Gross	$1,548,608	$1,461,084	$87,524
Operating expenses	948,934	898,517	50,417
Net earnings	$599,674	$562,567	$37,107
Interest	180,334	158,135	22,199
Earned on stock	419,340	404,432	14,908
Per cent on stock	8.43	8.17	....
Dividends	397,518	390,382	7,136
Surplus for year	21,822	14,050	7,772

It is noteworthy that the company has in the last two years made a marked reduction in operating expenses as compared with the two preceding years. The percentage of operating expenses to gross receipts in the last four years has been:

1896-97.	1895-96.	1894-95.	1893-94.
61.3%.	61.5%.	66.3%.	68.2%.

The growth in the company's business during the year was:

BUSINESS CONNECTED.

Incandescent lamps	208,954
Arc lamps	5,180
Motors (horse power)	6,824.7
Total equivalent in 16 c. p. lamps, March 31, 1897	355,140
Total equivalent in 16 c. p. lamps, March 31, 1896	315,732
Increase for fiscal year	39,408

Important changes in the company's funded debt were made during the year as follows:

New 5 per cent. bonds issued		$2,267,000
Retired—		
6 per cent. debentures	$712,000	
6 per cent. first mortgage bonds	130,300	
6 per cent. bonds of Chicago Warehouse and Manufacturing Company	125,000	
6 per cent. purchase notes	53,000	
		$1,020,300
Leaving balance of proceeds of bonds		$1,246,700

This balance has been applied to improvement of plant, extensions, etc. The company's unfunded debt shows a decrease of $175,229 as compared with the previous balance sheet. These changes leave the company with only the balance of the debentures, $1,483,000, and the $2,267,000 of new bonds outstanding. The bonds are part of the $6,000,000 authorized last summer, of which $3,733,000 more may be issued at any time for extensions and improvements or to retire the outstanding debentures. The remaining $1,024,100 is issuable only after an equal amount of capital stock has been issued and fully paid.

In the year just closed the company got comparatively no benefit on account of the reduction in interest on its funded debt. The offer under which the debentures were exchangeable for bonds terminated only on December 15. The Warehouse and Manufacturing Company bonds and the company's first mortgage bonds were called, payable March 1 last. The purchase money notes were called payable May 1 and were paid only a short time before that date.

Whatever extensions and improvements the company has made of recent years have been of the best possible character, and its expenditures on plant have been undertaken not merely to meet immediate needs but with regard both to future growth and to producing and transmitting current at the lowest possible cost. The pursuit of this policy has resulted in a remarkable record during the last four and a quarter years. On December 31, 1892, the company had outstanding $1,500,000 of capital stock and $130,300 of first mortgage bonds, a total of $1,630,300. The last balance sheet shows capital stock $4,975,900 and funded debt $3,750,000, a total of $8,725,900. Thus the company has increased its capitalization by $7,095,600 during four years of almost continuous depression in general business. Of this increase $2,195,000 was paid for the Chicago Arc Light and Power Company's property and business in 1893 and $4,500,000 in round numbers represents new money taken into the concern. The general depression has naturally had a very marked effect on the company's business, and while it has maintained, and earned, its 8 per cent. dividends, it has not reaped the advantage which it would have obtained under normal conditions from its large outlays.

The company has divided its surplus fund, transferring $200,000 to depreciation account and $20,000 to insurance fund. The company will ultimately carry its own insurance, increasing the insurance fund from time to time with that end in view. The charge to depreciation account is in accordance with the terms of the mortgage. It does not represent depreciation in the ordinary sense of the term, but is a fund against which extensions and improvements may be charged. The mortgage provides that certain sums must be set aside yearly, and the company may either charge them off or use the amount for actual extensions and betterments. It is the equivalent of a sinking fund, only the money, instead of lying in the hands of a trustee, goes into the company's property.

The balance sheet for the last two years, with comparisons, shows:

ASSETS.

	March 31, 1897.	March 31, 1896.	Increase.
Plants, real estate, etc	$8,630,330	$7,705,517	$924,813
Work in progress, etc.	136,405	109,915	26,490
Accounts receivable	197,799	190,329	7,470
Cash	206,541	48,920	157,621
Total	$9,171,075	$8,054,681	$1,116,394

LIABILITIES.

	March 31, 1897.	March 31, 1896.	Increase.
Capital stock	$4,975,900	$4,948,437	27,463
Bonds and debentures	3,750,000	2,503,300	1,246,700
Accounts, notes payable	131,066	304,426	*173,360
Open accounts	17,842	19,711	*1,869
Surplus fund	76,267	278,807	*202,540
Depreciation account	200,000	....	200,000
Insurance fund	20,000	....	20,000
Total	$9,171,075	$8,054,681	$1,116,394

GENERAL ELECTRIC ANNUAL MEETING.

The annual meeting of the General Electric Company was held May 11, when the old board of directors was unanimously re-elected. At the meeting 210,000 shares were represented. The directors are Gordon Abbott, Boston; Oliver Ames, Boston; C. A. Coffin, Schenectady; T. J. Coolidge, Boston; C. H. Coster, New York; T. A. Edison, Orange, N. J.; G. P. Gardiner, Boston; Eugene Griffin, Schenectady; J. P. Morgan, New York; R. T. Paine, 2nd, Boston; G. F. Peabody, New York.

The board will hold their next meeting the second Monday in June.

LEGAL NOTES

DECISION AS TO DUTIES ON CARBONS.

The point having been raised that carbons, as preparations from coal tar should come in free, of if not exempt should come in under the coal duties of 40 or 15 cents a ton, or not more than 20 per cent. ad valorem as non-enumerated manufactured articles, the Board of General Appraisers has overruled the protest and affirmed the collection of a duty of 30 per cent., as on articles composed of earthen or mineral substances. Another protest, on carbon electrodes for mineral reduction, claiming duty at 20 per cent. ad valorem, has also been overruled, and the 30 per cent affirmed.

NIAGARA POWER.

IN Ottawa the standing committee on miscellaneous private bills has reported adversely a bill which would give the Canadian Power Company the right to cut a canal through Queen Victoria Park at Niagara, on the Canadian side, for the purpose of generating 15,000 horse power. The bill asked that the work be declared one for the general advantage of Canada, but Mr. Irving of Toronto, who appeared to represent the Attorney General of the province of Ontario, stated that he considered the work a purely provincial matter. It will be recalled that questions relating to the respective rights of the Canadian Power Company and the Canadian Niagara Power Company have been submitted to the Court of Appeals by the council of the province of Ontario. The Canadian Niagara Power Company is controlled by the Niagara Falls Power Company, and it is paying an annual rental of $25,000 for the exclusive right to develop power in Victoria Park, work on which development was commenced on April 30. The fact that the Attorney General of the province of Ontario was represented at the hearing referred to in opposition to the Canadian Power Company would make it look as though the Ontario government was disposed to maintain the supremacy of franchises granted or approved by it so far as Victoria Park is concerned.

THE EFFECT OF THE BERLINER DECISION.

MR. T. A. ROSS, general manager of the Stromberg-Carlson Telephone Manufacturing Company, Chicago, writes us as follows in regard to the effect of the Berliner decision, on their business and the public generally:

For our part, we are jubilant over the decision and we consider it a signal victory for the opposition companies for the following reasons, which certainly appeal to common sense, viz.: The Supreme Court refused to consider the question of validity of the patent in view of the 1880 Berliner patent and other defences, thus compelling the Bell Company to settle the vital questions relating to anticipation by a protracted infringement suit, which cannot be settled for many years. The only court, Judge Carpenter of Boston, who passed upon the questions which will arise in the infringement suit, decided against the Bell Company, and it is reasonable to suppose that any other court considering the same questions will do the same thing.

The Appeal and Supreme Courts hold that these questions which will arise in an infringement suit could not properly be considered in a suit founded on fraud.

The Chicago "Record," in an editorial of May 11 sums up the situation better than we can do it, as follows: "The policy of the Bell Company in evading a decision upon all the grounds of invalidity that had been raised, and thus throwing away an opportunity to gain a clear title to the invention if it had a right to it, seems to lend color to the claim of the independent telephone companies that the Bell Company has really little faith in this patent, and that, instead of securing a judicial decision upon the merits of the case, it proposes to use the Berliner patent and the decision of the United States Supreme Court as a club over weaker corporations. In spite of all the claims that may be made by the American Bell Telephone Company and its agents and advocates, the decision of the Supreme Court of the United States is apparently of no practical value in continuing and sustaining the monopoly of the telephone industry."

As to the moral effect of the decision on public business, there is no question but what it will be more or less great until the public comes to learn that this is but another cloud the Bell Company has shrewdly thrown over the industry. Nerveless and weak-kneed investors will undoubtedly take alarm for the time being, but this decision gives to those best posted wonderful opportunities to make telephones while the clouds hang low.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 11, 1897.

Alarms and Signals:—

ELECTRICAL STRIKING AND ALARM ATTACHMENT FOR CLOCKS. B. De Witt, Terra Alta, W. Va., 582,273. Filed April 20, 1896.

Adapted for use in connection with ordinary striking clocks to provide means for striking the hours and half hours on electrical bells at places remote from the clock.

ELECTRICAL INDICATING DEVICE, W. W. Dean, St. Louis, Mo., 582,461. Filed Sept. 19, 1896.

An electrically operated visible signal of the self-restoring type.

Connectors, Conduits and Insulators:—

INSULATOR. W. G. Schnee, Pueblo, Col., 582,396. Filed Feb. 26, 1897.

An insulator having the top grooved to receive the conductor and provided with a cap adapted to hold the wire in place.

ELECTRIC CIRCUIT TERMINAL. E. N. Dickerson, New York, 582,462. Filed April 5, 1897.

Consists of a substantially U-shaped, flat portion, one of the arms of the U being provided with a rounded projection.

ELECTRIC CONTACT. C. C. Dusenbury, Lake Mahopac, N. Y., 582,464. Filed Feb. 8, 1897.

Designed to be substituted for a switch.

OUTLET INSULATOR. J. M. Anderson, Boston, Mass., 582,514. Filed March 16, 1897.

Consists of a sleeve of insulating material provided on its interior with screw threads.

Dynamos and Motors:—

ELECTRIC MOTOR. J. A. Mosher, Chicago, Ill., 582,218. Filed Feb. 9, 1893.

An armature of electro-magnets, consisting of a number of plates arranged in succession upon a shaft obliquely to its axis.

ARMATURE FOR DYNAMO ELECTRIC MACHINES. E. P. Clark, New York, 582,269. Filed July 16, 1896.

Consists of segments composed of H-shaped punchings from sheet iron.

FASTENING MEANS FOR CORE PLATES OF ELECTRICAL MACHINES. E. E. Nolan, Wilkinsburg, Pa., 582,481. Filed Jan. 20, 1897.

CORE FOR ELECTRICAL MACHINES. G. Westinghouse, Pittsburg, Pa., 582,494. Filed Jan. 20, 1897.

Comprises a casting having a cylindrical surface supporting laminæ, an annular clamping plate and a fastening ring interposed between the clamping plate and a shoulder on the casting.

Lamps and Appurtenances:—

CARBON FOR ARC LAMPS. J. D. Smith, Washington, D. C., 582,378. Filed March 1, 1897.

Comprises a carbon and a piece of insulating material attached to the carbon and interposed in the path of the arc to extinguish it.

Measurement: -

ELECTRIC METER. G. A. J. Telge, Oldenburg, Germany, 582,493. Filed Nov. 16, 1896.

The measurement of the current is effected by causing the current to influence the oscillations of the pendulum of a clock and from the difference in time effected is deduced the amount of current.

Miscellaneous:—

GOVERNING DEVICE FOR FLUID PRESSURE MOTORS. F. M. Rites, Ithaca, N. Y., 582,233. Filed Jan. 13, 1897.

A device for modifying the effects of inertia and other disturbing forces which is adjustable by electricity.

ELECTRICALLY PROPELLED AGRICULTURAL IMPLEMENT. H. Schimpff, Halle-on-the-Saale, Germany, 582,237. Filed Sept. 25, 1896.

An electric plow adapted to be moved along an anchored chain.

METHOD OF TREATING ARTIFICIAL DENTURES. E. L. Chaffin, Helena, Ark., 582,342. Filed Aug. 31, 1896.

Consists in plating plastic dentures with non-corrodible metal by means of electrolysis.

INCANDESCENT GAS BURNER AND MANTLE. W. H. Cottingham, Milwaukee, Wis., 582,459. Filed April 3, 1896.

Consists of layers of copper, platinum, and ruthenium, which have been electrically deposited upon a suitable base, and the base subsequently destroyed by heat.

Railways and Appliances:—

ELECTRIC TROLLEY DEVICE. W. M. Brown, Johnstown, Pa., 582,259. Filed Dec. 16, 1896.

Comprises a carriage carrying a contact maker, the carriage being adapted to slide transversely within a tube.

TROLLEY WIRE HANGER. J. E. Atwood, Stonington, Conn., 582,337. Filed Oct. 12, 1895.

Obviates the use of solder in fastening the conductor to the hanger.

SUPPORT FOR TROLLEY WIRES. E. J. Cook, Cleveland, Ohio, 582,344. Filed March 6, 1897.

A trolley car having a chambered groove adapted to receive a flattened wire when turned to an unusual position, and to retain it when in the normal position.

Switches, Cut-Outs, Etc.:—

ELECTRICALLY ACTUATED SWITCH. J. Bryan, Pittsburg, Pa., 582,262. Filed Aug. 1, 1896.

Electrically operated switch controlled by motorman on the car.

ELECTRIC SWITCH. W. J. Newton, New York, 582,303. Filed Jan. 28, 1897.

Flush switch.

Telephones:—

TELEPHONE TRANSMITTER. R. P. Green, Columbus, Ohio, 582,200. Filed Jan. 11, 1897.

Comprises an electrode consisting of oxygenated sulfid of copper in an envelope composed of zinc.

TELEPHONE TRANSMITTER. H. C. Alexander, Bonham, Tex., 582,513. Filed Dec. 4, 1896.

Of the granulated electrode type.

TELEPHONE. C. F. Dunderdale, Chicago, Ill., 582,522. Filed June 17, 1895.

Temperature compensating device for telephone receivers.

SYSTEM OF ELECTRICAL INTERCOMMUNICATION. E. A. Clark, Sioux City, Iowa; J. P. Ellacott & W. J. O. Johnson, Chicago, Ill., 582,578. Filed Sept. 28, 1893.

Means whereby the several subscribers of a system may place themselves in communication without the aid of a central operator.

TELEPHONE CONTROLLING DEVICE. T. A. Dull, Chicago. Ill. Filed Oct. 14, 1895.

Coin actuated telephone controlling device.

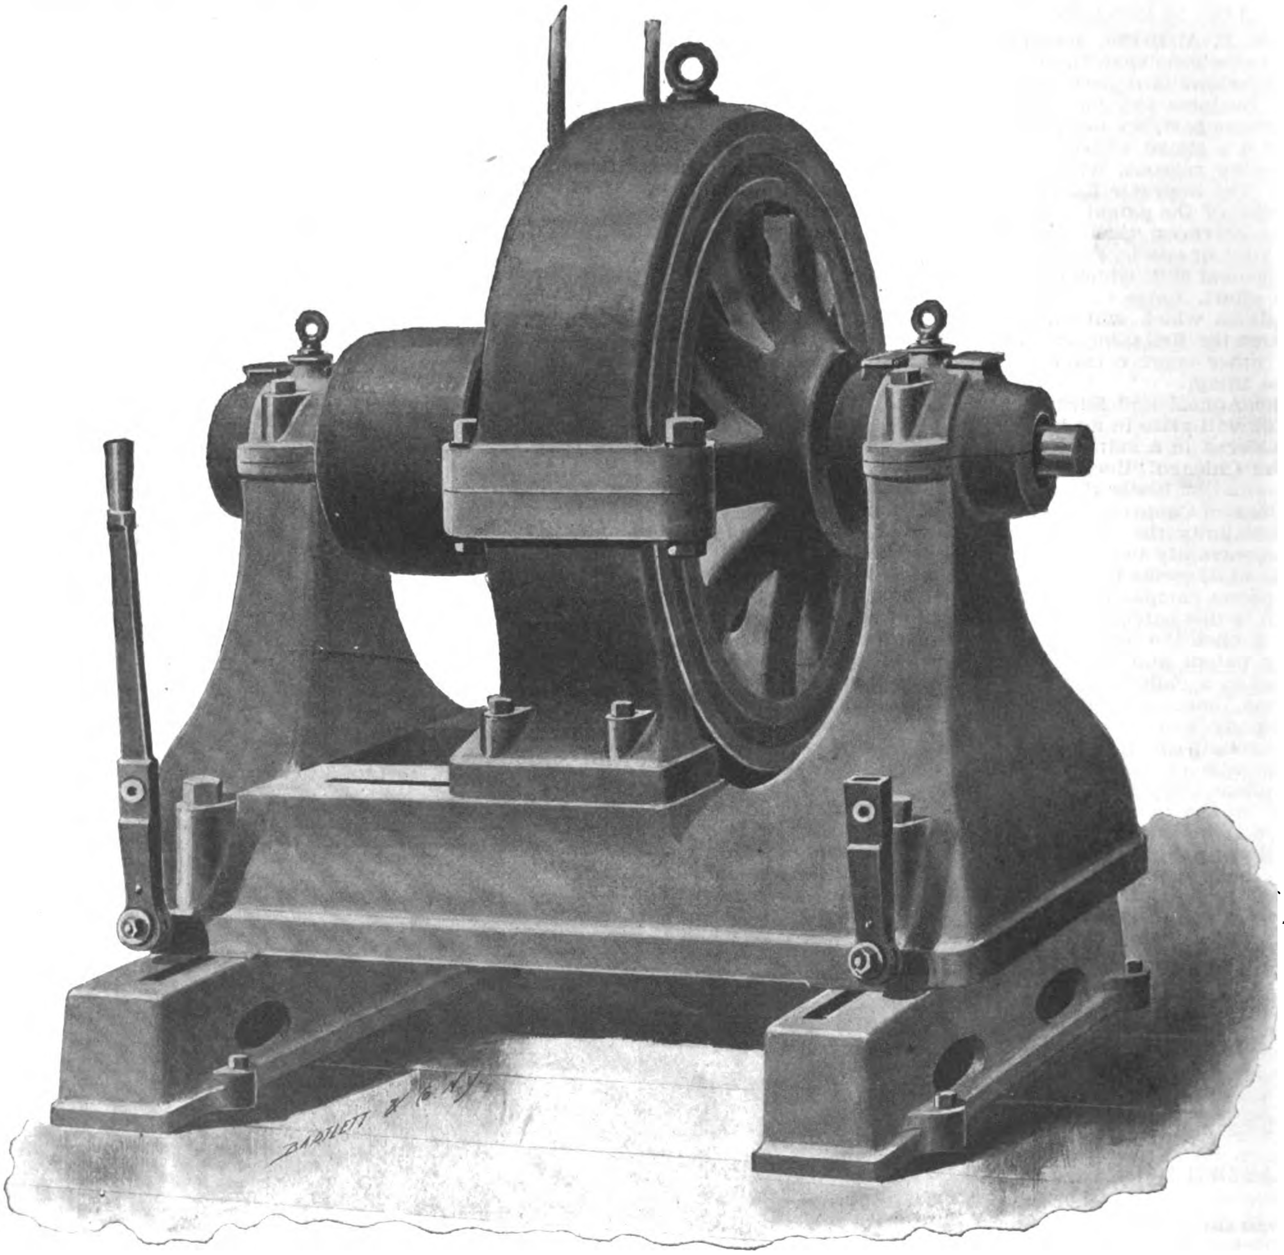
STOWE, VT.—Mr. H. M. Burgett and associates are building what is to be an electric road between Stowe and Waterbury, Vt. They expect to handle a large amount of freight. The organization is to be known as the Mount Mansfield Railroad Company, and P. D. Pike, of Stowe, is president. The road will give a beautiful ride of ten miles through the scenery of the finest mountain region in New England.

BALTIMORE, MD.—In view of the projected consolidation of the street railways, people have been buying up for future use large quantities of the tickets issued at the rate of 6 for 25 cents, thus making 20 cents on the dollar so long as their supply holds out.

TRADE NOTES & NOVELTIES

THE WALKER ALTERNATOR.

Up to recent date the Walker Co. had confined its activity to the manufacture of direct current apparatus, such as dynamos for railway and isolated plant work and to stationary and railway motors. The demands made upon it for arc and alternating apparatus have, however, been such that they could not be ignored, and the result has been the designing of complete systems of both types of the latter apparatus. The Walker arc lamp was illustrated in our last issue, and this week we are able to present an illustration and description of the new Walker alternator.



The New Walker Inductor Alternator.

This machine is of the "inductor" type, the inductor consisting of a solid iron casting keyed to the rotating shaft. The hub, together with the outwardly projecting arms or spokes with laminated iron tips, forms part of the magnet circuit. There are no windings upon this rotor, the function of which is (1) to provide a path for the magnetic field, and (2) as part of the magnetic circuit, to vary the position of the magnetic flux, relative to the armature coils.

To the interior of the fixed ring shown are secured annular laminations. These armature laminations are furnished with inwardly projecting teeth and support the armature coils. There are twice as many armature coils as there are inductor projections, and at any instant half the coils lie opposite these, and half opposite the spaces between the inductors. The armature lying external as it does to the inductor, gives room for ample cross section of conducting wire, without infringing on the space necessary for insulation. The coils, themselves, are thoroughly insulated in the process of construction; and again, the sides and bottom of the slots are lined with composite insulation of the best materials before receiving the coils. Thus the insulation between armature windings and frame is of the highest quality, and being upon the stationary portion of the machine, is not exposed to the slow disintegration which deteriorates some varieties of insulation upon revolving armatures.

The inductor and armature together form a discoidal box, the stationary armature ring being the periphery. One side is closed by the projecting arms of the inductor; the other by a casting continuous with the armature ring, and extending radially inwards, leaving only the necessary clearance between it and the inductor hub. Within this annular box, concentric with the shaft and securely bolted to the armature casting, is the coil supplying the excitation necessary for the machine. The magnetic lines generated by this coil, starting from the armature ring, flow inwards along the side of the armature casting, across the air-gap into the inductor hub, out along the inductor arms and through the laminated tips, across the air-gap into the armature teeth; the changing position of the inductor arms supply the variation of magnetic flux through the armature coils necessary to produce the required voltage.

The machine is so designed that any repairs, when necessary, can be readily and quickly effected.

KEYSTONE PORTABLE VOLTMETERS.

THE Keystone Electrical Instrument Company, of Philadelphia, announce that they are now prepared to offer a complete line of portable voltmeters for combined use on the direct and alternating current.

In the construction of these voltmeters nothing is incorporated which is subject to change or deterioration, and, having been calibrated from absolute standards of voltage, they may be relied upon to maintain their accuracy. The system is such that there is no magnetic lag nor any error due to self-induction, therefore they are independent of frequency variations on the alternating current.

They are mounted in highly polished mahogany cases with key lock and leather carrying handle. With each instrument is included a pair of flexible leads for which a special compartment is provided.

This line of voltmeters is the result of a large number of experiments covering several years followed by time tests in actual practice.

Two features are incorporated which busy users will appreciate; one is that the instruments are dead-beat without the use of a mechanical brake, and the second is that each instrument is provided with a switch for reversing the direction of the current flow through the voltmeter when used on direct current circuits. This latter enables the user to obtain mean readings easily and promptly, and, further, by turning the switch to the dead-point to throw the instrument out of circuit without disconnecting the leads.

These voltmeters are listed in ranges from 12 to 700 volts, single and double scales, so that all classes of testing work are provided for.

INFRINGEMENT OF MAGNOLIA METAL.

WE are in receipt of the following communication from Mr. E. C. Miller, vice-president of the Magnolia Metal Company, of New York City, under date of May 11:

We beg to inform you that the firm of Sugden, Pound & Wagner of London (former selling agents for Magnolia Metal in Europe, and who traded under the name of the Magnolia Anti-Friction Metal Company, of Great Britain, by special permission of our company) have been dispossessed of their agency by the English courts and that our London office and our foreign business are now under the management of Mr. Chas. B. Miller, the president of this company.

We beg also to inform you that Messrs. Sugden, Pound & Wagner were recently perpetually enjoined, together with the Atlas Metal Company, Limited, of London, John Sugden, Max Wagner, Arthur George Brown, the Globe Engineering Company, Limited, of Manchester; the Atlas Bronze Company, Limited, and the Atlas Bronze Company from continuing the fraudulent business of making an anti-friction metal and branding it with the trade mark of the Magnolia Metal Company, of New York, imitating their ingots, marking the boxes in which the metal is packed, "Made in the United States," and otherwise deceiving and imposing upon purchasers of anti-friction metal in Great Britain and Europe.

Justice Collins heard this case and gave judgment against Sugden, Wagner, Brown, the Globe Engineering Company, Limited, and others, for selling counterfeit goods and deceiving the public by representing that the goods they sold were made in the United States by the Magnolia Metal Company.

An appeal was taken from the injunction above referred to. This appeal was tried before the Court of Appeals, Lord Esher presiding, and the perpetual injunction granted by Justice Collins was confirmed. It was in this trial that Lord Esher denounced the action of the parties above named and characterized their performance as "A Disgusting Fraud."

It has come to our notice that parties in this country have attempted to perpetrate a similar fraud, and we now have one Western firm in the courts over this matter, and we desire through your columns to warn the engineers and the general public, users of anti-friction metal, against these fraudulent attempts to pirate and appropriate the use of our trade marks and name of our metal.

Every bar of Magnolia metal bears the steel stamp of the Magnolia flower, and the impression of the steel die "Patented June 3, 1890," and "Manufactured in the United States," with the exception of the metal manufactured by this company in Russia, which bears the stamp of the Magnolia flower and the words "Manufactured in Russia."

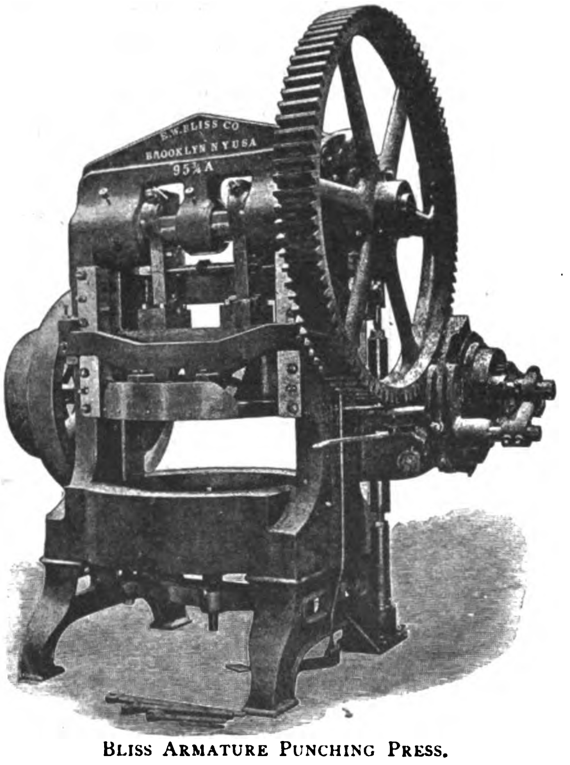
Will you kindly publish this letter and help in that way to give publicity to the facts set forth and thereby protect, in some measure, American manufacturers who are being wronged by foreign as well as domestic competitors.

BLISS ARMATURE DISC CUTTING PRESSES.

THE requirements of armature work for electric motors and dynamos have led to the construction of presses which differ in essential points from those used for other styles of sheet metal work.

The usual form of armature is made up of annular discs with notches on the outside or inside circumference. As it is essential to have the outside and inside exactly concentric, it has been found best to adopt dies which, by cutting them simultaneously, eliminate the inaccuracies which are almost unavoidable when the cutting is done in two or more operations. In many cases the notches and key-slots are also punched at the same time, all of which calls for tools having "throw-out pads" in addition to the cutting parts, so as to automatically push the disc and scrap out of the dies and punches.

These "throw-out pads" are now usually operated by means of heavy springs, which are not always reliable, and consume a great deal of the power of the press. The press shown herewith is designed to operate these "throw-outs" in a positive manner, and consume but little of the power of the press. The bottom plate which operates the "die-pads" through radial slots or pin-holes in the bolster, is actuated by an outside crank connection, or by means of two rods connecting it directly with the slide, as shown. Two cross-pieces, adjustably attached to the frame of the press, actuate the "throw-out pads" of the punches by striking against them on the return motion of the main slide.



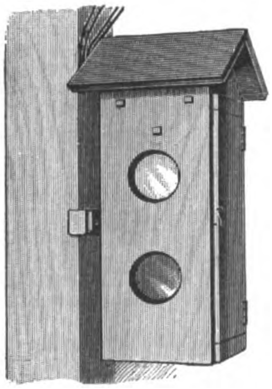
BLISS ARMATURE PUNCHING PRESS.

This press is designed for the class of work mentioned by the E. W. Bliss Company, 43 Adams street, Brooklyn, N. Y. It will cut the outside and inside simultaneously on plain discs up to 31½ inches diameter, and up to 14 or 15 inches diameter, when all the outside notches are also to be cut at the same stroke. It may also be used for cutting segments or sections complete at one stroke with all their teeth or holes up to 31½ inches long.

ELECTRIC BLOCK SIGNAL FOR TROLLEY ROADS.

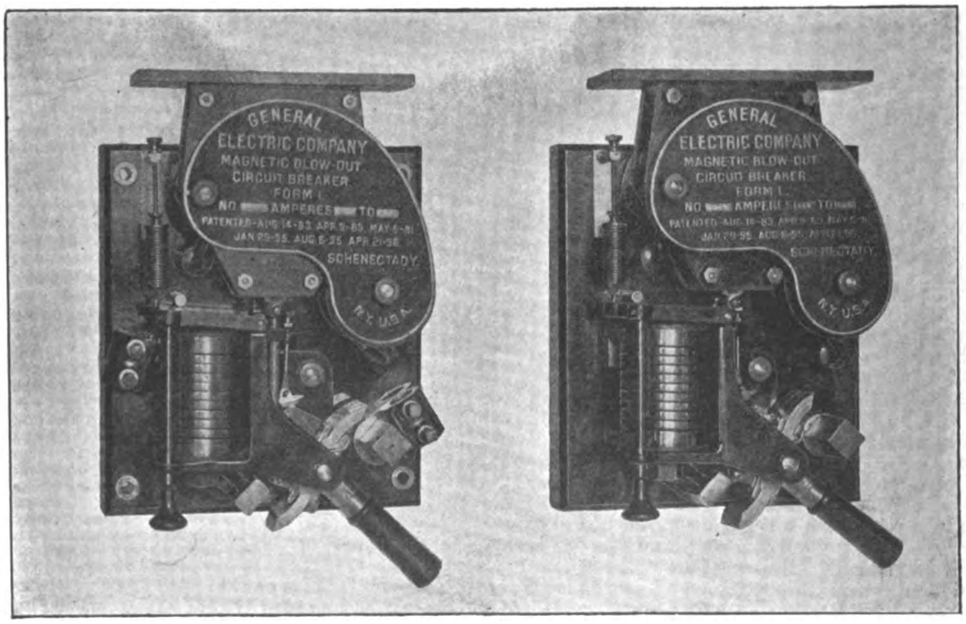
THE Automatic Block Signal Company, of 136 Liberty street, is introducing a novel and ingenious automatic electric block signal that should be hailed with delight by both managers and patrons of single track trolley lines, as it does away with the annoyances incident to cars going in opposite directions meeting between turnouts.

The accompanying engraving shows the appearance of the box containing the signal. One of these boxes is placed on a pole near the turnout at each end of the "block" or section of single track. The box has two lenses on each side, the two upper lenses having green glass and the two lower ones red glass, with a group of lamps between each pair of lenses. Each box has wires running to automatic contacts on the in and out trolley wires of the switch. Two wires also connect the two signal boxes with each other.



AUTOMATIC ELECTRIC BLOCK SIGNAL FOR TROLLEY ROADS.

The operation is as follows: The trolley wheel of a car on passing over the turn-out to enter the block strikes the corresponding automatic contact which lights the lamps that show the green signal in the signal box at entering end and the red signal at the other end of the section. On passing out of the block or section the trolley wheels strike the automatic contact on the "out" side of the turn-out trolley wire and this shuts off the current from the lamps at both ends of the section. It will thus be seen that this block signal not only indicates at each end when a car is on the "block," but also the direction in which it is moving.



THE GENERAL ELECTRIC CIRCUIT BREAKER.

These signals have been in use by the Paterson (N. J.) Railway Company and by the New Jersey Electric Railway Company, in Hoboken, since October, 1896, and have given perfect satisfaction.

NEW G. E. FORM L CIRCUIT BREAKER.

THE well-known automatic circuit breaker of the General Electric Company, known as form K, for heavy currents, is now followed by one for use with smaller currents, that is, for 100 to 500 amperes. It is known as the form L and as with the K, may be used on any potential up to 750 volts.

The deleterious effect of arcs on unprotected contact parts, destroys in a short time their usefulness, introducing a serious problem on all circuit breaking apparatus, and the greater the voltage and current the greater the difficulty presented in handling arcs. To eliminate the destructive effect of arcs on contacts the magnetic blow-out principle was applied, and by this a means is provided for destroying the arc at the moment of its formation. The addition to a switch thus equipped of a tripping device to open the circuit as soon as a predetermined current flows, gives an automatic circuit breaker unsurpassed for reliability and convenience.

The form L circuit breaker is substantial in construction and compact in form. It is mounted on a slate base 11 by 12½ inches, and the maximum overall measurement from the back of the base is 6 inches. It can be provided with either front or back connections. Its action is similar to that of the form K circuit breaker, adopted so widely in power stations for use with heavy currents. The current passes through built-up leaf contacts to the tripping coil, the armature of which actuates the tripping device. An adjustable tension spring holds the armature away until sufficient current flows to overcome its pull, drawing the armature to the magnet coil.

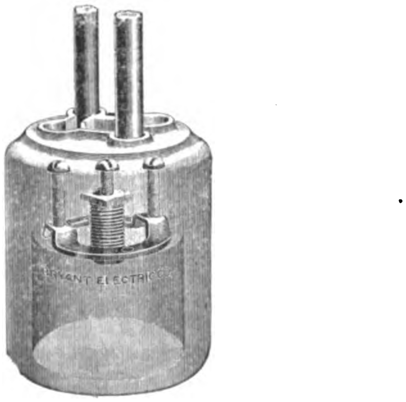
The leaf contacts are held normally against the main contact blocks. When the tripping armature is drawn to its magnet, the main contact is released and the circuit instantly opened by the action of the main spring. To prevent arcing at the main contact, the current is shunted through a secondary contact plug protected by the blow-out magnet. This plug is not withdrawn until after the leaf contacts have left the contact blocks and all tendency to arc, therefore, is confined to this point, where the magnetic action prevents it from doing damage. The blow-out magnet and secondary contact are in series contact. Owing to their high resistance, practically no current flows through them until the circuit through the main contact is opened, when they take the whole current, creating the magnetic field and extinguishing the arc indepenently and apart from the main contact.

The marked rating of a circuit breaker, as 100-500, indicates the lowest current that will automatically open the circuit and the maximum normal current carrying capacity. The circuit breaker is set to open at any desired current from its lowest rating to 50 per cent. in excess of its highest rating, by adjusting the calibrating spring of the tripping armature. An indicator on the adjusting stud registers with well-spaced marks on a brass scale, showing the current at which the circuit will be opened.

The handle of the form L circuit breaker is removable, but is automatically locked in place so long as the circuit remains closed. It can be removed only when the circuit breaker is open. Moreover, when the handle is removed the circuit breaker cannot be closed. This interlocking device allows feeder circuits to be kept open at the will of a single operator, avoiding to a large extent any accidental closing.

THE BRYANT WEATHER-PROOF SOCKET.

THE accompanying engraving represents a new weather-proof socket just brought out by the Bryant Electric Company, of Bridgeport, Conn. The special features of this new socket are the method of sealing in the wires, which makes it absolutely weatherproof, and the length of the porcelain skirt, which is unusually long and which fully covers the lamp base. This style of socket is made with T-H and Westinghouse bases.



BRYANT WEATHERPROOF SOCKET.

SALES OF BALL ENGINES.

The Ball Engine Company, Erie, Pa., report the following recent shipments of engines for electric purposes: Vulcan Coal Co., Treveskyn, Pa., one 225-h.-p. direct connected to generator; Queen City Electric Light and Power Company, Clarksville, Tenn., one 125-h.-p. engine; Langhorne Electric Light and Power Company, Langhorne, Pa., 3d order, one 200-h.-p. engine; Maxwell House, Nashville, Tenn., 3d order, 125-h.-p. engine, direct connected to dynamo; Rockville (Md.) Water Works, one 80-h.-p. engine; Wilmington Gas Light Company, Wilmington, N. C., 3d order, one 300-h.-p. cross-compound engine; Pennsylvania Tube Works, Pittsburg, Pa., one 60-h.-p. engine; Seaboard Air Line, Portsmouth, Va., one 70-h.-p. engine, direct connected to dynamo; Apollo Iron and Steel Works, Apollo, Pa., 4th order, one 150-h.-p. vertical cross-compound, direct connected alternating machine; Kirk's Soap Factory, Chicago, Ill., one 50-h.-p. engine, direct connected to dynamo; Lexington Hotel, Richmond, Va., one 40-h.-p. engine; (Congo O.) Mining Co., Congo, O., one 175-h.-p. engine, Wainwright Brewing Company, Pittsburg, Pa., one 80-h.-p. engine, direct connected to dynamo; Fox Pressed Steel Company, Pittsburg, Pa., one 100-h.-p. engine, direct connected to dynamo; F. O. Norton Cement Co., Binnewater, N. Y., one 60-h.-p. engine; Lakewood Hotel and Land Company, Lakewood, N. Y., one 165-h.-p. tandem compound engine.

BRISK TRADE OF THE BERLIN, IRON BRIDGE CO.

The Berlin Iron Bridge Company, of East Berlin, Conn., are working full time, and report that Spring business is opening up in quite a brisk manner. They have a large number of contracts on hand, including a water tower at North Berwick, Me.; large school building at East Albany, N. Y.; steel frame work for the Providence Institution for Savings, at Providence, R. I.; steel frame work for the new Waterbury, Conn., Savings Bank; large addition to the Waterbury, Conn., Farrel Foundry and Machine Company; an addition to the boiler plant of the Bay State Brewery, in South Boston, Mass.; steel trusses for the Opera House at Corinth, N. Y.; steel work for the new Public Library Building, at Providence, R. I.; an addition to the boiler plant of the Connecticut Hospital for the Insane, at Middletown, Conn.; new pumping station for the York, Pa., Water Company; addition to the boiler plant of the Dunnell Manufacturing Company, at Pawtucket, R. I.; fire proof building for the Guggenheim Smelting Company, at Perth Amboy, N. J.; steel frame work for a church, at Bartlett, N. H.; bridge at Charlemont, Mass.; large steel bridge for Somerset County, N. J.; a steel bridge for the town of Coventry, Conn.; steel highway bridge for the town of Hermon, N. Y.; large city bridge at Vergennes, Vt.; large bridge for the S. D. Warren Company, at Cumberland Mills, Me.; also highway bridge at Wilmington, N. Y.

THE STANDARD AIR BRAKE CO.'S NEW CATALOGUE.

A CATALOGUE that entirely satisfies the eye and mind and gives the feeling of a piece of work thoroughly well done, is that just issued by the Standard Air Brake Company, of 100 Broadway, E. J. Wessels, general manager. It is 9 by 12, in stiff paper cover, and contains about 40 pages of text, put together in a very illuminative and instructive manner. The uses of the Standard brake are dealt with, in relation to street cars, freight cars and locomotives, cable cars, rack-rail cars, lift bridges, etc. These various applications are dealt with in detail, and are shown in many handsome illustrations. A large part of the text, and that which for most people will be of chief interest, is devoted to a discussion of air brake problems, and to a very complete illustrated description of the mechanism and the method of employing it. The introduction of air brakes on street cars has been uphill work, but the day seems fast approaching when no car that ought to have such brakes will be without them. To that end such admirable trade literature as this must contribute powerfully. The company will be glad to send copies on application to any one who is genuinely interested. They want every shot to tell.

THE BELTLESS AGE.

Mr. A. M. Lozier, M. E., of the Bullock Electric Manufacturing Company, says in the "American Machinist": "When electrical transmission stepped to the fore, even the best equipped factories presented a most inconsistent appearance. Their condition might be compared to two strong iron links of a chain held together by a piece of string, for on the one hand their boilers and engines were of the best and most economical types, and on the other hand, their tools or printing presses were compact, automatic and highly efficient. But the connecting link, the means of transmitting the power from the engine to the tool, was a weak one, a great source of waste in power and a relic of conservatism. It is astounding that for years, thousands (indeed, one may say millions) of horse-power hours have been wasted in the mere friction load of shafting and belting, without any serious consideration of the matter by mill owners and printers. Records of tests made in over two hundred representative factories and printing establishments of this country alone show, as an average, that about 50 per cent. of all the power generated by the engines has been wasted in belt or rope transmission of power."

ADVERTISERS' HINTS

THE CHICAGO FUSE WIRE AND MANUFACTURING COMPANY have removed to 152-154 Lake street, occupying larger quarters in their new location.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., will send a free sample of "Highland" soldering paste on application. One pound of the paste is equal to three gallons of soldering solution.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY have secured offices in the Bowling Green Building, 11 Broadway, New York.

THE ELECTRIC ENGINEERING AND SUPPLY CO., Syracuse, N. Y., illustrate their "ad" in this issue with a cut of their style "K" "Baby" switch in 35 and 50 amperes capacity.

THE ELECTRO-CHEMICAL STORAGE BATTERY COMPANY, 36 Broad street, New York, have moved their factory to 35 Gold street, which will greatly facilitite the prompt delivery of goods.

THE MITCHELL TEMPERED COPPER COMPANY, Corry, Pa., advertise pure hardened copper electrical appliances.

WM. S. TURNER, M. S., is now located at 1 Nassau street, New York.

THE INGERSOLL-SERGEANT DRILL COMPANY draw attention to the Pohlé system of raising water by means of compressed air. This system is designed specially for pumping water from artesian wells. Besides the economy claimed for the system, sand or grit does not affect it, the water is purified and one air compressor will pump from any number of wells regardless of distance. The company's interesting catalogue contains descriptions of a number of successful installations of this kind.

WESTERN NOTES

THE AMERICAN RHEOSTAT COMPANY, Milwaukee, Wis., report that business has been very good with them for some time past and that they have found it necessary to run their factory at night in order to enable them to make prompt shipments. Amongst the most important orders which they have lately supplied were all the printing press controllers, field rheostats, and starting boxes for the new Germania Building, Milwaukee; a 200-horse-power rheostat for the Chicago Edison Company, Washington street station, and several others to different parts of the country.

KEELYN & SMITH, electrical engineers and contractors, Milwaukee, Wis., have removed from their old quarters at 148 Second street to much more commodious premises at 169 W. Water street.

D. L. BATES & BRO., Dayton, Ohio, are running night and day to fill the unprecedented demand for their ceiling fans.

NEW YORK NOTES

L. E. FRORUP continues as general sales agent of Schiff, Jordan & Co., with offices at 232 and 234 Greenwich street, New York. The sales of the well-known carbon handled by this company during the past three or four weeks have been enormous.

REPORTS OF COMPANIES

ERIE TELEGRAPH AND TELEPHONE CO.

FOURTEENTH ANNUAL REPORT.—FOR THE YEAR ENDING DECEMBER 31, 1896.

The principal assets of the Erie Telegraph & Telephone Company consist of an ownership of stock in the following telephone companies:

Sixty-five per cent. of the capital stock of the Cleveland Telephone Company. Capital issued, $1,700,000. Territory, Cuyahoga County in Ohio, which includes Cleveland.

Seventy per cent. of the capital stock of the Northwestern Telephone Exchange Company. Capital issued, $2,000,000. Territory, the States of North Dakota, South Dakota, excepting the Black Hills District, and Minnesota, excepting the City of Duluth. (For list of cities see below.)

Seventy per cent. of the capital stock of the Southwestern Telegraph and Telephone Company. Capital issued, $3,000,000. Territory, the States of Arkansas and Texas. (For list of cities see below.)

To the Stockholders:

Your Directors respectfully submit the Fourteenth Annual Report of the Corporation, showing the operations of this company and of the three telephone companies (in which this company owns a controlling interest), for the year ending December 31, 1896, together with a statement of assets and liabilities.

	1883.	1894.	1895.	1896.
The Cleveland Telephone Co.	1,500	3,936	4,390	4,681
The Northwest. Telep. Ex. Co.	1,933	5,479	5,968	6,538
The Southwest. Tel. & Tel. Co.	2,558	6,759	8,233	10,170
Total	5,991	16,174	18,591	21,389

Net increase for 1896, 2,798.

Total number of metallic circuit subscribers included in the above, 2,061.

Total Number of Exchanges.	1883.	1894.	1895.	1896.
The Cleveland Telephone Co.	3	3	4	4
The Northwest. Telep. Ex. Co.	13	15	15	16
The Southwest. Tel. & Tel. Co.	38	38	44	45
Total	54	56	63	65

The Erie Telegraph and Telephone Company was organized in June, 1883, and originally owned the telephone properties now operated by the Cleveland Telephone Company, the Northwestern Telephone Exchange Company, and the Southwestern Telegraph and Telephone Company. In 1887 an arrangement was entered into with the American Bell Telephone Company whereby perpetual contracts were issued covering the three sections mentioned, and the properties were conveyed by bills of sale to the corporations now owning them, this company retaining a controlling interest, heretofore mentioned, in each company. The growth of the business since 1883 has been marvelous, and the year 1896, notwithstanding the general unsatisfactory condition of the business of the country, shows a greater increase, comparatively, than any previous year.

The expenditure upon the plant and equipment during the year has been—

For new construction	$828,317.65
For maintenance	199,823.78
For real estate	206,273.07
Total	$1,234,414.50

The number of subscribers has increased from 5,991 in 1883 to 21,389 in 1896, a net gain of 15,398.

Income and expenditures since 1883 have been as follows:

Gross income	$10,745,911.59
Gross expenses	6,927,918.04
Net earnings	$3,817,993.55
Included in the item "Gross Expenses" is the sum of	$1,832,989.71
Expended in improving the plant, to which must be added the cost of all classes of extensions, and the cost of real estate	3,006,470.25
Grand total cash disbursement upon the plant since 1883 (exclusive of the cost of the original properties and rights)	$4,839,459.96

The Erie Telegraph and Telephone Company has paid 53 dividends since the organization of the company, including the dividend declared by the directors January 29, 1897, from the earnings for the quarter ending December 31, 1896.

Real Estate.—For an exchange of about 700 subscribers, where an underground system is necessary, it is advisable that a permanent location be secured for the "Central Office." The company now owns land and buildings in the following cities:

	Value.
Austin, Texas	$3,500.00
Galveston, Texas	55,000.00
Houston, Texas	37,000.00
Little Rock, Ark.	6,500.00
San Antonio, Texas	18,000.00
Cleveland, Ohio (Main)	250,000.00
Cleveland, Ohio (Branch)	20,000.00
St. Paul, Minn. (purchased Jan. 1, 1897)	50,000.00
Total	$440,000.00

There is now being constructed for our use at Minneapolis a building, which we have the option of purchasing, that will cost, with the land, a sum not exceeding $125,000. We also have under consideration a permanent location at Dallas and Fort Worth, in Texas, although at present we are well situated, under satisfactory leases.

It is the policy of the management to purchase land and erect buildings only of sufficient size and practically for our own use, as far as possible, so as to avoid the trouble of renting offices.

Underground.—The Sub-Companies commenced burying their wires in 1888, and now have 11,808 miles of wire working underground, in the following cities:

Houston, Texas. (Conduit laid ready for wires.)	
San Antonio, Texas	550 miles
St. Paul, Minn.	1,690 miles
Minneapolis, Minn.	2,173 miles
Cleveland, Ohio	7,395 miles
Total	11,808 miles

Toll Lines.—A decidedly valuable auxiliary to the exchange telephone service is the toll line department, and we have spared no effort to extend this branch of the business to every city and town in our vast territory, wherever the lines can be operated profitably. With the exception of about seventeen hundred miles of iron wire to small branch stations, our entire system of eleven thousand five hundred and twelve miles is composed of heavy copper metallic circuits, and we are prepared to give an excellent long distance service throughout our territory. The time is not far distant when we expect that the American Telephone and Telegraph Company (the Long Distance Company) will build to points in our territory, thereby connecting our extensive system with the great long distance service of the United States.

Most of the toll line construction has been done during the years 1895 and 1896, under the direction of our efficient superintendent of construction, Mr. P. G. Reynolds. The lines in most cases have been constructed outside of the railroad right of way and parallel thereto on land purchased by the company, and are built in a most able and thorough manner.

In the Northwest we are operating 5,054 miles of toll wire, as follows:

Circuits.	From	To	Pole Miles.	Copper Wire Miles.	Iron Wire Miles.
1	Grand Forks	Park River	54	108	...

60			1,452	*4,398	656

*Includes two wires, one circuit, No. 8 copper wire, Minneapolis to Fargo. This wire is of sufficient size to enable Park River, N. D., to talk with Bar Harbor, Maine, when the connection is made between Milwaukee and Minneapolis. The distance from Milwaukee to Minneapolis is 340 miles, and from Park River, North Dakota, to Bar Harbor, Maine, is about 2,148 miles. Longest circuit operated by this company is from Park River in North Dakota to Parker in South Dakota, via Minneapolis, which is 700 miles.

In the Southwest we are operating 6,458 miles of toll wire, as follows:

Circuits.	From	To	Pole Miles.	Copper Wire Miles.	Iron Wire Miles.

1	Columbus	Schulenburg	23	...	23
1	Hempstead	Wallis	38	...	38
1	Houston	Eagle Lake	69	138	...
1	Houston	Morgan City	26	...	52
1	Galveston	Texas City	7	14	...
63	Total Texas		1,762	5,034	745
11	Total Arkansas		340	384	295
74	Total Southw'n Tel. & Tel. Co.		2,102	5,418	1,040

The longest circuit operated by this company is from Clarksville, Texas, to Galveston, Tex., 600 miles. The construction of 165 miles of line between Memphis, Tenn., and Pine Bluff, Ark., and 163 miles from Malvern, Ark., to Clarksville, Tex., would connect all of Arkansas and Texas with the general long distance system of the United States. The longest telephone circuit in the world would be Bar Harbor, Me., to Galveston, Tex., 2,738 miles.

TOLL LINE SUMMARY.

Circuits.		Pole Miles.	Copper Wire Miles.	Iron Wire Miles.
60	Northwestern Telephone Exch. Co.	1,452	4,398	656
74	Southwestern Teleg. & Teleph. Co.	2,102	5,418	1,040
134	Total	3,554	9,816	1,696
	Miles iron wire		1,696	
	Total miles wire		11,512	

Grand total number of miles of wire in operation December 31, 1896 42,032

As follows:

	Underground.	Aerial.	Toll.	Total.
The Cleveland Telephone Co.	7,395	6,588	195	14,178
The Northwestern Telephone Ex. Co.	3,863	5,573	5,054	14,490
The Southwestern Teleg. & Telep. Co.	550	6,356	6,458	13,364
Total	11,808	18,517	11,707	42,032

Extensions.—To establish ample facilities in the Northwestern and Southwestern sections for the large and increasing toll business, and to reach important points demanding service, it will be necessary to build within the next eighteen months 842 miles of pole line and 3,982 miles of wire. We estimate of the total expenditure for extensions of the plant and real estate for the year 1897 will be as follows:

For New Construction	$500,000.00
For Real Estate	200,000.00
Total	$700,000.00

Funds.—To provide funds for the future growth of the business, the capital stock of the Cleveland, the Northwestern and the Southwestern companies is increased from time to time as the work progresses, the American Bell Telephone Company taking and paying for their pro rata of the increase, at par, with this company. For this purpose, to December 31, 1896, the number of shares sold in each company has been as follows:

	Shares.	Par Value.
The Cleveland Telephone Company	9,000	$900,000.00
The Northwestern Telephone Exchange Co.	21,429	1,071,450.00
The Southwestern Telegraph & Telephone Co.	10,000	1,000,000.00
Total	40,429	$2,971,450.00

To enable the Erie Telegraph and Telephone Company to take its proportion of new stock issued to date and that that may be issued in the future, you have authorized an issue of four million 5 per cent. bonds, payable in 1926. All of the bonds have been sold, to be delivered as the company may require funds. One million of this issue has already been delivered, making the total outstanding indebtedness $2,243,000.00

THE SUB-COMPANIES HAVE NO OUTSTANDING INDEBTEDNESS.

I can conservatively say that the affairs of the various corporations are in good hands throughout, that we may look forward for continued prosperity in every section of the territory.

For the Directors,
LEVI SPRAGUE, President.
Lowell, Mass., U. S. A., January 29, 1897.

The Electrical Engineer.

Vol. XXIII. MAY 26, 1897. No. 473.

ELECTRIC LIGHTING

THE VILES ELECTRIC LIGHT AND POWER PLANT, MIDDLESEX, VERMONT.

THE stimulus which has been given to the development and utilization of water powers by the introduction of electric transmission methods is becoming more and more pronounced as time passes. Water falls that had been entirely neglected in the past are now being developed on all sides and electric machinery is called in to aid in bringing the energy to the place where it can be utilized profitably.

A little over a year ago, Mr. J. S. Viles, proprietor of the Pavillion Hotel, and one of the most enterprising citizens of Montpelier, Vt., recognizing the fact that the Winooski River afforded a source of power, began the development of a power site at Middlesex, a point on the river about six miles from Montpelier. The Winooski River drains a water shed of 600 square miles and it was estimated that about 2,500 horse power could be counted on for the average throughout the year.

The operators began by the construction of a dam 35 feet high and 148 feet long, built in the shape of a V with the tip of the angle pointing down stream. The overflow or mill pond caused by the erection of the dam is the old river bed and runs back about two miles, the dam itself being at the end of a canal 600 feet long, built to change the course of the river, which was found to be necessary. Besides the main dams there are two side dams by which the water may be emptied out of the canal in case of need.

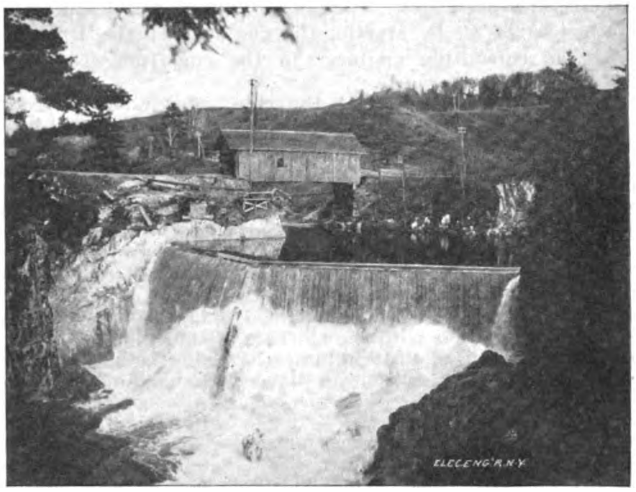
THE VILES WATER POWER TRANSMISSION PLANT, MIDDLESEX, VT.

The main building, illustrated in the accompanying engraving, is 104 feet long by 35 feet wide, with a lean-to wheel house of the same size. The water is led to the wheel house through two penstocks, 8 feet and 13 feet in diameter, respectively, and 175 feet long, with shells of one-quarter-inch boiler iron. These were built up on the site. In the wheel house there are erected three 42-inch Alcott special turbines, built by Messrs. T. C. Alcott & Co., of Mount Holly, N. J., each wheel being capable of delivering 750 horse power under a head of 48 feet. The draft tubes are 60 feet in length and give a vacuum of 21 inches.

The driving pulleys attached to the turbine shafts are 10 feet in diameter with 60-inch face; they run at 198 r. p. m., and belt direct to the line shaft which is driven at 350 feet per minute.

From the latter there are driven at present two 150-kilowatt Westinghouse three-phase alternators at a potential of 2,500 volts, and two exciters of 7½ horse power each running at 125 volts.

The switchboard is of the Westinghouse standard type, of marble, arranged so that either dynamo can be connected to any circuit. The potential is regulated by a Chapman voltage controller arranged with double-pole, double-throw switch, so that it can be connected to either generator. Running in front of all the dynamos and the switchboard is a heavy rubber mat for the attendants to stand on, thus affording immunity from accidental grounds.

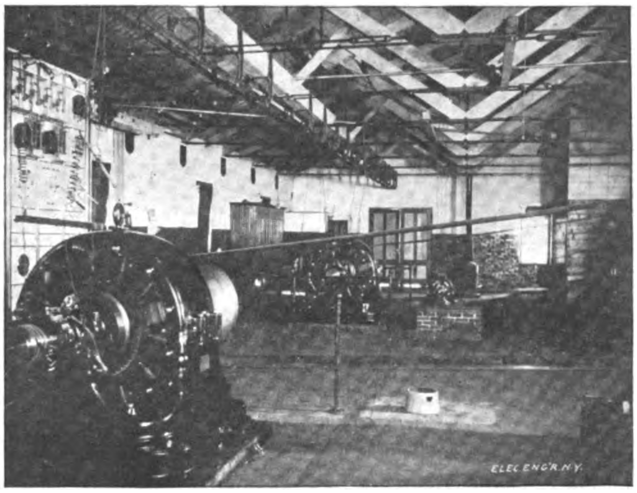


DAM OF MIDDLESEX, VT., WATER POWER TRANSMISSION PLANT.

The transformers are situated in the frame building shown in the engraving, which contains three 50-kilowatt Westinghouse transformers, with room for six more. The circuits are provided with Wurts lightning arresters with choking coils.

At present a circuit of No. 4 wires carries current at 2,500 volts to Montpelier, and another, of No. 6 wire to Barrie, at 5,500 volts, for the time being, which will be raised to 10,000 volts when the load increases. The step-up transformers are oil insulated. Porcelain insulators are employed on the line.

The distance to Barrie is 13 miles and with a motor load of 200 horse power there is a drop of 9 per cent. in the line. The motors are of the Westinghouse three-phase type, without brushes, and range from 1 to 20 horse power capacity. Besides these the station supplies about 3,000 incandescent lamps.



INTERIOR OF MIDDLESEX, VT., WATER POWER TRANSMISSION PLANT.

The plant is in charge of Superintendent E. A. Earle, and has been in continuous operation without interruption since April, 1896. The management has it in contemplation to put in a 150-kilowatt railway generator and storage batteries,

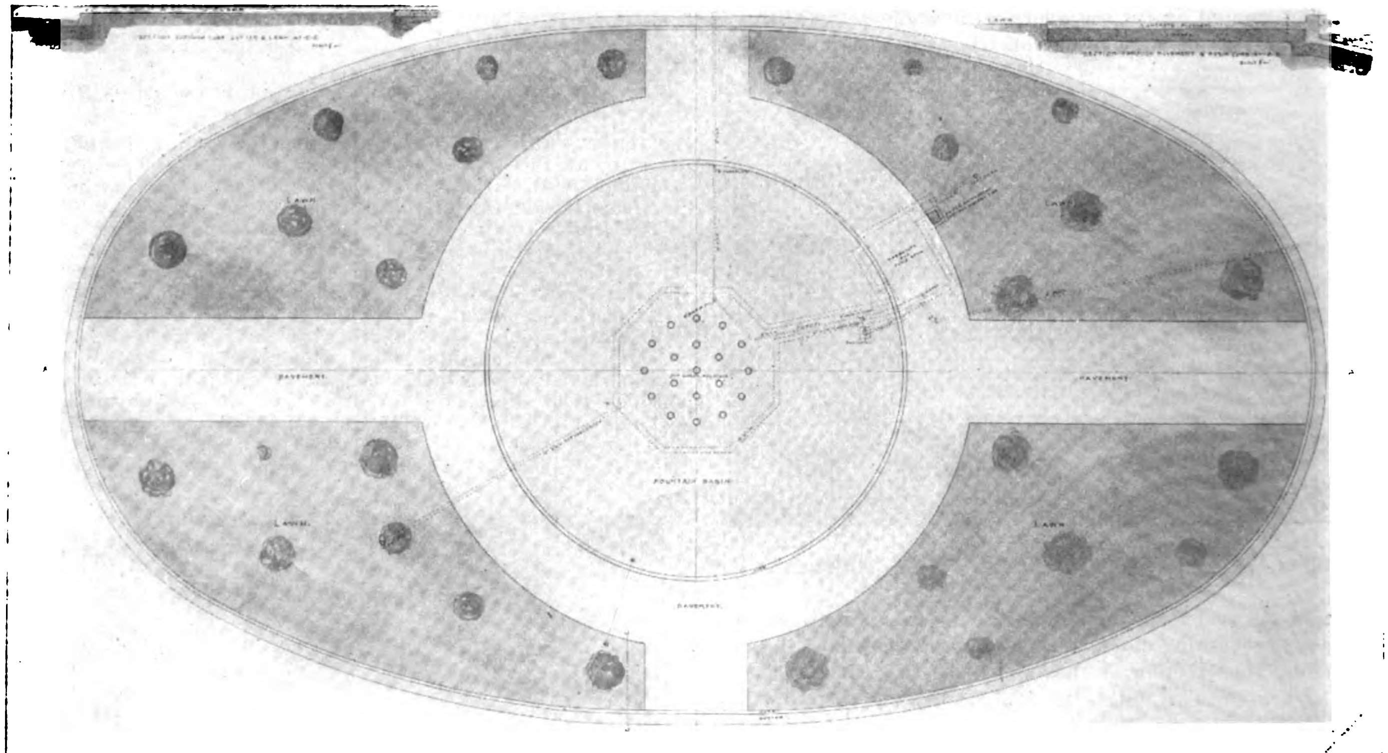
AN ELECTRIC FOUNTAIN FOR BROOKLYN, N. Y.

PARK COMMISSIONER DETTMER of Brooklyn, N. Y., has awarded a contract for the construction of an electric fountain in the park plaza to the Wilson & Baillie Manufacturing Company. The contract price is $24,500, and for this sum the company agrees to provide a fountain in complete working order and to operate it for one month to demonstrate its perfection before the final payment is made. The plans for this fountain were designed by F. W. Darlington of Philadelphia, who has constructed several fountains of a similar character in other cities. The park commissioner has secured the services of C. C. Martin, the engineer of the Brooklyn Bridge, as consulting engineer in the construction of this fountain.

The contract provides that the contractor shall take the plaza as it exists to-day and erect a fountain which will have a capacity of throwing 100,000 gallons of water per hour, and that the current required will approximate less than 100 h. p. This amount of electricity is to be furnished free of cost to the city by the Brooklyn Heights and the Nassau companies, which have entered into an agreement with the park commissioner, each to supply one-half of the current required.

The circumference of the basin will be 370 feet and will be constructed of kosmocrete. Under the center of this basin will be a pit in which will be placed a large portion of the machinery connected with the shifting of the colored plates of glass which are used to illuminate the rising columns of water. Leading from this pit to a place at the edge of the fountain basin will be a tunnel which will connect the pit with the operating room, where the person in charge of the fountain will stand, looking out of a window six inches above the water, thus enabling him to see the various combinations which his manipulation of the machinery will produce.

The electrical apparatus consists of nineteen automatic focusing arc lamps, connected in three series. Each lamp will be of 6,000 candle-power, mounted on an adjustable stand, which permits of its being raised from four to six feet from the floor of the pit, and thus providing different angles at which the light may be thrown upon the ascending water. Three rheostats are to be furnished, one for each series of lamps, and each lamp is to be provided with large silver parabolic reflectors. The colored glass is to be operated by compressed air and controlled by electricity. There will be eighty incandescent lights ranged about the wall of the basin. The combinations possible by this arrangement of pipes and lights are innumerable. They will consist of fancy jets, umbrellas, ball sprays, straight sprays, wheat sheaves, rings, fans, funnels and combination jets. One curious display that can be given at the fountain is the throwing of a wide sheet of spray upon which pictures may be displayed. The first exhibition to be given at the fountain will be on July 4, if the contractor completes his work within the required time.



PLAZA AT PROSPECT PARK, BROOKLYN, N. Y., ARRANGED FOR DARLINGTON'S ELECTRIC FOUNTAIN.

ARTIFICIAL LIGHT; MODERN METHODS COMPARED—ELECTRIC-INCANDESCENT, WELSBACH, ACETYLENE.—II.

(Concluded.)

BY PROF. D. S. JACOBUS.

IN the Pictet works, in Paris, acetylene is compressed in steel cylinders that have previously been tested to 250 atmospheres. A short time ago a cylinder of this description, of large capacity, exploded at the Pictet works, killing two workmen and injuring another. The two men were torn to pieces, and a part of the works was blown down.

There is another case on record where a cylinder of acetylene, fitted up to light a dwelling house, exploded and seriously injured a tinman and his laborer, who were at work upon the premises.

An explosion of liquid acetylene, resulting in the death of four persons, took place in a Berlin suburb some time in last December. This explosion occurred at the time when a chemist named Isaac, who had for some time experimented with acetylene with a view of depriving it of its dangerous qualities, was preparing an exhibition of the results of his experiments, a record of which was to be presented to the German Emperor. The use of acetylene is prohibited in Germany, owing to its explosive character, and it was to deprive it of its dangerous qualities that Mr. Isaac made his experiments, and thereby met his death.

By an explosion of a cylinder of liquid acetylene at New Haven, in January, 1896, three persons were killed and four injured. The explosion occurred while experiments were being made on a regulator to reduce the pressure in the tanks to that required at the burners.

An explosion occurred in Jersey City about one year ago, when it was attempted to generate the gas from the carbide under pressure. This shattered the roof of the building, the apparatus being in the upper story, and demolished the wood work in the neighborhood of the generator; but fortunately no one was near enough to the generator at the time of the explosion to be seriously injured.

All the above explosions are cases in which the acetylene was under pressure, and exploded in the same way as ordinary dynamite or gunpowder; that is, by the decomposition of its own elements without the aid of the oxygen of the air. There have been accidents, however, where it is probable that the explosions were caused by the mixture of air with the acetylene.

For example, an accident took place at Lyons a few months ago, in a café lighted by acetylene generated on the premises. The explosion produced much damage and killed two persons.

Another explosion, or, perhaps, it might be called a case of accidental ignition of the gas, occurred in Jersey City last January. The liquid acetylene was being blown from a tank into a felt bag, in order to obtain solidified acetylene, or snow, in the same way that snow may be obtained from carbonic acid. An explosion of the escaping gas occurred, which set fire to the mass of solidified acetylene. One of the workmen was severely burned about the face and hands.

In view of the above practical demonstration of the danger of acetylene gas under pressure, it would seem unwise to use it in that way; and even when generated on the premises at atmospheric pressure great precautions should be employed to prevent explosion, on account of the admixture of air.

RELATIVE COSTS FOR EQUAL ILLUMINATION.

The costs per hour for a production of 16 candle-power of light, in the city of New York, are shown in Table II:

TABLE II.

		Cents.
Incandescent electric light at 1 per cent per lamp hour		1.0
Illuminating water gas.	Ordinary burner, 4 cubic feet, at $1.25 per 1,000 cubic feet.	0.5
	Welsbach burner, 1.14 cubic feet at $1.25 per 1,000 cubic feet	0.17
Acetylene employed for Municipal distribution.	Calcium carbide, furnished to gas company and converted into gas for $40 per ton*	0.5
	Calcium carbide, furnished to gas company and converted into gas for $19.50 per ton†	0.17

* To replace flat-flame burners.
† To replace Welsbach, cost of replacing mantles of Welsbach lamps included in the estimate.

The price at which calcium carbide would have to be furnished for domestic lighting, to be as economical as kerosene oil at 8 cents per gallon, is $45 per ton. The compressed liquid acetylene would have to be furnished for 6½ cents per pound to be as economical as kerosene.

It will be seen from Table II. that to compete with an ordinary illuminating water gas selling at $1.25 per 1,000 feet in municipal distribution, the carbide would have to be furnished to the gas company and converted into gas for $40 per ton, to net the gas company the same profit, and to be as economical to the consumer as the ordinary illuminating gas burned in the flat-flame burner. To be as economical to the consumers as ordinary gas burned in Welsbach burners, it would have to be furnished to the gas companies and converted into gas for $19.50 per ton.

It is further shown that, to be as cheap as kerosene in domestic lighting the carbide would have to be supplied to the consumer at $45 per ton, and the compressed liquid acetylene would have to be supplied at 6½ cents per pound.

The figure for the Welsbach burner in Table II. is obtained by adding to the cost of the gas 0.03 cent per hour per 16 candle-power to replace mantles, which are assumed to cost 50 cents, and last 500 hours on a lamp furnishing 50 candle-power. The difference in cost in favor of the Welsbach will disappear to a great extent in practice; for if ordinary gas burners are replaced by the Welsbach, the total amount of illumination, as a rule, becomes greater, and if three times as much, the cost of gas to the consumer per month would be the same with the Welsbach as with the ordinary gas burners.

The figures for the acetylene are obtained in the following way:

Assume a plant which is furnishing an illuminating water gas at $1.25 per 1,000 cubic feet. If this plant were converted into a plant to furnish acetylene gas, there are certain expenses, such as the cost for distribution, including the maintenance of the plant, collection of bills, office expenses, etc., that would remain about the same per day for the acetylene as for the water gas. These constant expenses would practically be all other expenses, except those involved in making the gas and storing it in the holder. To simplify matters, let us consider a plant of any given capacity, say 500,000 cubic feet of gas per day. Then we have:

Paid by consumers per day, 500,000 cubic feet, at $1.25 per 1,000 cubic feet	$625.00
Cost of gas in holder, at 40 cents per 1,000 cubic feet*	200.00
Constant expenses per day, together with profit of gas company	$425.00

To furnish the consumers with the same amount of light that they obtained with the flat-flame burners and the ordinary illuminating gas, would require one-tenth the volume of acetylene, hence one-tenth of 500,000, or 50,000 cubic feet of acetylene would have to be stored in the holder for $200, in order that there should be the same profit to the gas company. This 50,000 cubic feet would be produced by 5 tons of calcium carbide; hence, the cost of 1 ton of calcium carbide, together with the cost of converting the carbide into gas, would be $40, to compete with ordinary gas at $1.25 per 1,000 cubic feet, burned in flat-flame burners.

To compete with ordinary gas burned in Welsbach burners, the amount of acetylene stored in the holders would be in the ratio of 70 to 200 to the amount of ordinary gas required for equal illumination; or, we would have to store 175,000 cubic feet in the holder for $200. In addition to this, the cost of the mantles replaced per day in the Welsbach lamps should be included, which would be $140, making a total of $340. To produce the 175,000 cubic feet would require 17.5 tons of calcium carbide, and it would have to be furnished at the gas works and converted into gas at about $19.50 per ton.
